Without such general-practitioner bed facilities I would have been unaware of the rise at 1 a.m. The difference between English and Canadian cheeses was interesting, as at that stage we were warned only of blue-vein cheeses. The following day the patient remarked she had had so much benefit from Actomol she would give up cheese for life. I regret I had not heard of phentolamine (Dr. R. K. Rondel, 11 November, p. 357).—I am, etc.,

Welwyn Garden City,

Treatment of Myocardial Ischaemia

SIR,—In your leading article (4 November, p. 249) you do not mention the role of anticoagulant therapy in the treatment of angina pectoris. This is an important omission, as there is evidence that the outlook for males with angina without frank infarction is considerably improved by anticoagulant therapy.^{1,2} I believe that all such cases should receive anticoagulant therapy as soon as the diagnosis is made, provided there is no contraindication, and thereby reduce the incidence of subsequent myocardial infarction

with its mortality in hospital of about 20%. My policy for some years has been to use anticoagulant therapy on all male cases of angina provided they are breadwinners and below the age of 70. This policy has been shown to pay dividends in the form of diminished mortality. The age limit is not critical.—I am, etc.,

G. R. ROYSTON.

Oxygen Concentrations in Tents

SIR,—The article by Dr. H. Simpson and Dr. Doreen J. Russell (28 October, p. 201) indicates the variability in the relationship between oxygen inflow rates and the concentrations found within tents and incubators. Our own investigations^{1,2} have shown that, after a tent or incubator has been opened for nursing procedures, it can take a very long time for the oxygen concentration to rise to

by Simpson and Russell between the "ideal" levels (presumably plateau levels) and the random samples taken during routine clinical use.

Continuous recordings of the changes in oxygen concentration in tents and incubators have led us to believe that, if any particular high level is required, it is essential to monitor the oxygen percentage and regulate the inflow

FIG. 1.—Oxygen concentrations measured within an Oxygenaire Junior Oxygen Tent. Note the gradual rise to plateau following routine nursing procedures. The two plateau levels (approximately 50% and 60%) are due to normal variations in seal. FIG. 2.—Same tent and patient as in Fig. 1. Note that frequent openings of the tent do not permit the attainment of a plateau.

a plateau, unless there has been a period of flushing. The gradual rise is illustrated in Fig. 1, although at lower inflow rates we have found this may take about one hour. If a tent or incubator is opened frequently the oxygen concentration may not attain a plateau; Fig. 2 shows a typical recording of changes in oxygen concentration during intensive nursing care. We have also found that the plateau concentration is affected by the efficiency of the sealing of a tent (as shown by the two plateau levels in Fig. 1), and by the temperature difference between the inside of an incubator and its surroundings.

In view of the influence of these factors it is impossible to predict the oxygen concentration from the inflow rate. This is well demonstrated by the wide discrepancy found

rate accordingly. Furthermore, we have found that the site of sampling is not critical and that readings taken from a central position are representative of the concentrations throughout the tent or incubator.

The authors wish to thank the Editor of the *Journal of the Royal College of Surgeons in Ireland* for permission to reproduce Figs. 1 and 2.

Obstetric Forceps or Vacuum Extractor?

SIR,—I cannot let the condemnation of the vacuum extractor in your leading article (23 September, p. 753) pass without comment. Having used this instrument with increasing frequency in the past four years, I have come to regard it as very safe for both mother and babe. Indeed, this has been shown conclusively by many authors and latterly by Bird¹ and again by Fahmy.² This is also my interpretation of the paper in the *American Journal of Obstetrics and Gynecology* to which you refer.³

The ventouse can be used in practically every case where forceps are indicated, and provided the classic requirements for the application of forceps are fulfilled it is a very safe instrument even in the hands of the novice. For the skilled obstetrician, as you most rightly point out, it also has the advantage that a patient can be delivered safely before complete dilatation of the cervix where there is urgent need for delivery. Further, it should be remembered that a young doctor can be trained to use this instrument safely and effectively in weeks, as compared to the many months required for training in the use of forceps. This is of particular importance in a country like Australia, where the country doctor has to put his hand to everything and often to cases which would be referred to specialist care in the cities. This instrument is also favoured by obstetricians in the so-called underprivileged countries for much the same reasons.

It seems a pity that you pay so much attention to this article and, in my opinion, misinterpret it. The many publications which emphasize the safety of the ventouse to both mother and child cannot be ignored. Finally, I must disagree with your statement that the vacuum extractor has no place in the district or in a general-practitioner maternity unit. These are the very situations where the instrument stands supreme.—I am, etc.,

Perth,
Western Australia.

SIR,—It is with considerable dismay that I have just read your leading article "Obstetric Forceps or Vacuum Extractor?" (23 September, p. 753). It suggests a parochial approach to the subject in the confines of obstetrics carried out by "the trained obstetrician" in a well-developed country. However, it is almost certainly fair to state that most complicated deliveries in the world are carried out by doctors who are not specialists in obstetrics, and the lesser skill required to apply the vacuum extractor, as opposed to forceps suggests that some points in your article may merit reconsideration. Even so, enlightened obstetricians in Europe such as Chalmers,¹ Fothergill,² Willocks,³ and Snoeck⁴ are replacing forceps with the vacuum extractor. Donald's remarks on the instrument in his *Practical Obstetric Problems*⁵ are particularly relevant.

In developing countries, with exceedingly few obstetricians about, the situation is even more poignant. Apart from being easier to apply, it can be used without anaesthesia, or

by local infiltration of the vulva only, in emergencies of foetal distress (although pudendal block is probably desirable), making the delivery just as quick as with forceps, with which anaesthesia is essential.

It is the writer's impression that it is merely tradition that makes forceps the instrument of choice in delay or foetal distress in the second stage. Dalley⁶ has said, "I could deliver safely any baby with the vacuum extractor that I could deliver alive by forceps," and Lange⁷ has concluded that there is less danger for the mother and only half the perinatal mortality. These remarks must be even more relevant with the limited obstetric skill available in developing countries, where disasters with forceps have been so frequent in the past that the caesarean section rate has risen to high percentage levels, this being undesirable for several reasons, until the vacuum extractor arrived. The relative ease with which an occipito-posterior can be delivered with the vacuum extractor may surprise many obstetricians who prefer the often difficult manual rotation or Kiellands forceps. This is certainly contrary to your own comments on this point.

It is difficult for those pre-eminent in the considerable skill needed to apply forceps to turn their attention to an instrument that may appear to usurp their prowess, but there are those of us who work as general duty medical officers, but have complicated obstetrics thrust upon us, and feel that the introduction of the vacuum extractor is the greatest advance in obstetrics since the advent of ergometrine, when considering the best management for our patients.—I am, etc.,

SIR,—Those who use the vacuum extractor to drag a baby through an undilated cervix admit the procedure carries with it the serious risks of brain damage, uterine rupture, and ruined uterine supports with subsequent prolapse. These risks should never be taken.

With good antenatal care, selective booking, careful observation during the first stage of labour, anticipating—rather than awaiting—foetal distress, and deciding on termination of labour at the latest by the eighteenth hour from its onset (or before, if it is clear that labour is halted) and while the condition of the mother and baby remain good; then, if the cervix is not fully dilated, a caesarean section should be done.—I am,

Mayday Hospital,
Croydon, Surrey.

A. CLIFT.

Deaths from Tuberculosis

SIR,—One must be grateful to Dr. A. Pines (18 November, p. 416) for drawing attention to the dangers to the community from the pool of drug-resistant, positive-sputum patients at large. Certainly there are reasons enough for making all possible efforts

to deal with their tuberculosis, but Dr. Pines has enumerated some of the difficulties.

These patients are largely from a group who have failed to stay the course in hospital, will not voluntarily return on any terms, and who cannot be relied upon to take the drugs conscientiously while remaining in their homes. The public health hazard is the real issue, I believe, rather than the mortality in this select circle of sufferers, many of whom were saved from death by the advent of the standard chemotherapeutic agents; but not before extensive lung damage had been done. Surely the latter is responsible for the gloomy figures. Do we know that adequate treatment with the second-line drugs means a longer life? Did the 33% die of their tuberculosis or from secondary infection?

If these patients resist institutional care, for their manifold reasons (largely psychological), chest physicians must continue to treat each individual as a particular and personal problem in his own environment, and the special centre will have empty beds until winter infection and respiratory failure force the victim to enter on a stretcher.—I am, etc.,

Brighton Chest Clinic,
Brighton, Sussex.

F. B. MEADE.

Smallpox Revaccination

SIR,—I was interested to read Dr. T. McL. Galloway's letter (16 September, p. 740) about smallpox revaccination. I agree with his plea in favour of vaccination.

I have been involved personally in two outbreaks of smallpox. On both occasions it was most remarkable how the disease picked out those individuals among the contacts who had never previously been satisfactorily vaccinated for one reason or another. Virulent smallpox is a killer and is so awesome that the possible side-effects of vaccination are of small significance in its presence. That has been my experience. The public will not thank the medical profession for underestimating the risk of a smallpox epidemic occurring in a poorly vaccinated population.

Until a more reliable alternative to vaccination is available, we doctors, when discussing the possible side-effects of vaccination with our patients, should tell them as well of the ravages of clinical smallpox and of the problems which arise when vaccination is not performed timeously and efficiently. Incidentally in a series of half a million vaccinations in my city there has been no fatality nor permanent disability reported among those concerned.—I am, etc.,

Screening for Phenylketonuria

SIR,—Drs. J. B. P. Stephenson and M. S. McBean (2 September, p. 582) drew attention to the lack of success in detecting phenylketonuria by early screening with Phenistix. This prompted us to investigate the stability of phenylpyruvic acid on towel napkins and also cellulose disposable napkins.

Freshly voided urine was used, to which sodium phenylpyruvate 25 mg./100 ml. was added. At this level a definite positive reaction was obtained from Phenistix when

dipped into the urine. When 5 ml. of this was applied to a 3-in. × 3-in. (7.5-cm. × 7.5-cm.) doubled piece of towel, a much reduced colour was observed on testing, and after an hour several skilled observers recorded a negative or doubtful reaction. The cellulose napkin, when used in the same manner, gave a definite positive even after two hours. These findings were consistent on four separate occasions. Quantitative estimation suggested some instability on the towel napkins associated with urine of high pH, but results varied and difficulty with turbidity from traces of detergent left from washing were experienced. However, it was found that the quantity of urine taken up by a Phenistix was much less from towel-type napkins than from cellulose or by direct dipping, as shown by the increase in weight. Average of 10 tests: dipping 29.4 mg., cellulose 39.5 mg., and towel 16.5 mg.

We suggest that this reduced uptake may be responsible for a lowering of sensitivity when Phenistix is used to detect phenylpyruvic acid on towelling napkins, especially when the urine has been given time to spread over a larger area from the original point of application. Perhaps the use of cellulose napkins would increase the detection rate of phenylketonuria to an acceptable level, as they appear to provide a more favourable material for an adequate transfer of urine to Phenistix.—We are, etc.,

Mercury Perchloride in Surgery

SIR,—We were interested in the letter by Mr. D. H. Patey (28 October, p. 238) suggesting that an accurate evaluation be made of the use of mercury perchloride in eradicating malignant cells from operation wounds. Like Mr. Patey, we too had not found any evidence of this having been done, and began some experiments some nine months ago. It is too early yet to make a complete evaluation, but our preliminary results using T₂₄₁ sarcoma cells in C₅₇ mice are encouraging and are summarized below.

Wounds Seeded with Sarcoma Cells

Irrigating Solution	Saline	Hypo-chlorite	0.1% Mercury Perchloride
Number of mice used	98	82	47
Number of mice in which tumours grew	88	40	11
Percentage in which tumours grew	90	49	23

In our earlier experiments^{1,2} we found that, using carcinoma cells under similar experimental conditions, cetrimide solution was more effective than other agents tested in preventing growth of malignant cells in operation wounds. The other agents tested included nitrogen mustard solution and hypochlorite solution.

In view of the favourable early results using mercury perchloride, we are currently comparing the effects of mercury perchloride solution with other irrigating solutions, including 1% cetrimide solution, in experi-

mental wounds seeded with carcinoma, sarcoma, and melanoma cells.—We are, etc.,

Oculogyric Crisis after Phenothiazines

SIR,—A nurse, aged 21, was recently admitted to this hospital with a severe oculogyric crisis following an injection of Fentazin (perphenazine) 10 mg. given for unexplained vomiting. She also complained of a choking sensation, had severe trismus, and presented a dramatic clinical picture.

In view of the fact that this appeared to be an extrapyramidal syndrome, as described in the manufacturer's literature, she was given atropine (0.6 mg.) as a potent anti-Parkinsonian drug. Pethidine (50 mg.) was also given. This was followed by a complete remission of symptoms within 10 minutes. There was a minor recurrence two hours later and she was given a second dose of atropine (0.6 mg.). After this she had no further symptoms.

Although this complication of Fentazin therapy is mentioned in the manufacturer's literature there is no reference to treatment.

This particular patient gave a history four months before of taking perphenazine tab. 4 mg. b.d. for five days without any adverse effect. This raises the possibility that the patient had been sensitized by the earlier administration of the drug, but such sensitization does not appear to have been previously described.—We are, etc.,

Safety of Dimethoate Insecticide

SIR,—The organophosphate anticholinesterase insecticide dimethoate is widely used in many countries for the systemic control of insects on food crops. At harvest some recently treated crops contain a small residue of dimethoate, from 0.05 up to 1 p.p.m. The safety of such residues to consumers of the crops is clearly an important matter.

Toxicological studies conducted before marketing showed that dimethoate intake rates as high as 0.04 mg./kg. bodyweight per day produced no detectable effect on whole-blood cholinesterase (ChE) values in rats (trial duration 6–12 months) or in human volunteers (duration one month). Individual human subjects were also given 0.13 and 0.26 mg./kg./day respectively for 21 days without detectable effect.¹ A special F.A.O./W.H.O. committee responsible for reviewing

safe levels of pesticides in food was naturally reluctant to accept data on individual subjects, and recommended the maximum allowable intake rate for dimethoate as 0.004 mg./kg./day.² This is the intake rate shown harmless to humans but reduced by a safety factor of 10. This recommendation tended to limit the permissible uses of an efficient insecticide with an excellent record of safe use in the field. Further studies were therefore desirable.

We now report extended observations on the response of humans to the daily ingestion of dimethoate, and in particular on the daily intake rate required to cause depression of whole-blood ChE values.

Thirty-six male and female adult volunteers without occupational exposure to organophosphate insecticides were arranged in groups and given repeated doses of dimethoate as indicated in the Table. Actual dosage was on five days per week, and each daily dose was therefore seven-fifths that shown in the Table. Missed doses of one or two days were made up by double doses on the day before or after. The dimethoate was administered as a flavoured aqueous solution. Venous blood samples were taken twice before and once or twice per week after dimethoate dosage started. ChE in whole blood was measured by the electrometric method of Michel³ and its depression taken as the critical first response to dimethoate. Activity in red cells and plasma were also determined separately. The study was under close medical supervision, and inquiry was also made for any effects other than ChE depression, though none was detected.

The Table summarizes the experimental plan and results of the study. ChE values are expressed in "cholinesterase units" (ΔpH/hr. × 100). Groups D and E were made up of previously discontinued Groups A and B, and were included to confirm at higher dosage levels the response seen in Group C.

The results show that no significant change occurred in Groups A and B. ChE values in Group C began to show a slow downward trend by day 20, and this continued to the end of the test at 57 days. Groups D and E showed the same effects at an earlier stage, and a somewhat faster rate. The rate and extent of red cell ChE depressions closely paralleled those of whole-blood ChE in Groups C and D. No localized gastrointestinal or other clinical effects occurred in any group.

From this study we concluded that dimethoate ingestion by humans at the rate of 0.4 mg./kg./day or above will cause a slow decrease in whole-blood ChE activity, but that at 0.2 mg./kg./day and below such an effect is most unlikely to occur. (Eight subjects were studied at a mean intake rate of 0.2 mg./kg./day. Their range of ChE activity before ingestion was 108–148 units (mean ± 2 standard deviations) and after 39 days was 102–146 units.)

It is therefore suggested that the experimentally adduced "no-effect level" for dimethoate ingestion by small groups of humans may now safely be taken as 0.2 mg./kg./day, which when reduced by a safety factor of 10 would imply an acceptable daily intake rate

Group	No. in Group	Daily Dose mg. Dimethoate	Duration of Test (days)	Mean Whole Blood ChE		Mean Weight (kg.)	Daily Intake Rate (mg./kg./day)
				Before	At End		
A	12	5	28	114	110	74	0.068
B	9	15	39	128	124	75	0.202
C	8	30	57	121	92	71	0.434
D	6	45	45	113	74	77	0.587
E	6	60	14	121	96	60	1.02

of 0.02 mg./kg./day. This is equivalent to the daily consumption by 60-kg. humans of 1 kg. of foodstuff containing 1.2 p.p.m. dimethoate residue. It bears a safety factor of at least 10 before the slightest effect on blood ChE activity would occur, and (from animal studies) a safety factor of about 400 before the first signs of clinical toxicity would arise. The full details of this study will be reported elsewhere. It is hoped that the findings may extend the permissible usage of an important and safe insecticide.

Grateful acknowledgement is made to the 36 volunteers concerned and to Soc. Montecatini (Milan) for providing the necessary materials.

Injury from High-speed Drills

SIR,—A serious ophthalmological hazard exists to dental practitioners from the new high-speed drills used for cavity preparation in teeth. Particles of filling or other dental debris may be projected at great speed into the orbital region of the operator, and cause damage to the eye.

In a recent case a fragment of tooth substance, propelled in this way, caused a severe corneal abrasion, which prevented the dental surgeon from working for a considerable period of time.

The necessity to wear some form of eye protection, such as goggles or spectacles, while using these drills cannot be too strongly stressed.—I am, etc.,

Eastman Dental Hospital,
London W.C.1.

Psychotropic Drugs

SIR,—As the co-author of the first British paper on phenelzine¹ I should like to comment on the views of Dr. P. Leyburn and his colleagues (18 November, p. 417).

In designing that first trial I was deeply concerned about the dangers of prescribing a placebo for depressed patients, since suicide is a possible outcome of imperfectly treated depressed patients. That risk was taken in the trial described but was not taken in any subsequent trial. The M.R.C. trial² expected a large number of investigators to take a similar risk, and this is one reason why I did not take part in the M.R.C. trial. In the design of any further trial one would hope that the M.R.C. would take the advice of people like Dr. P. J. Dally (28 October, p. 233) who are engaged in active clinical psychiatry. The previous trial was concerned with a type of patient who is found only in the pages of the older history books on psychiatry.

One of the hidden advances that monoamine oxidase inhibitor drugs and tricyclic compounds have given us has been the dis-

covery of hitherto unsuspected varieties of depression. The important task now is to marry symptomatology up with treatment. No single antidepressant drug is a specific cure for all varieties of depression.

It is time that clinicians ceased to be afraid of the dangers of these drugs. I have not seen one death from them in eight years of use, but I have seen several deaths from suicide in that period. Yet the deaths from suicide appear to be fewer than they were before these treatments were available. It would be of value for investigators to use the suicide rate as an index of success or failure in treatment.

In conclusion, it is important to remember that the elimination of suicide in depression is the main goal of all types of treatment. The suicide rate is still comparable to the death rate from road accidents, but the research and publicity directed towards its elimination compare very unfavourably with the efforts of the Ministry of Transport in dealing with its particular problem.—I am, etc.,

Surgery in Pulmonary Tuberculosis

SIR,—Your leading article "Surgery in Pulmonary Tuberculosis" (21 October, p. 127) defined six groups of patients who still require surgical treatment to complete their recovery. The fourth group contained "a few patients with 'healed cavities' which have become secondarily infected with aspergillus fungus. . . ."

The British Tuberculosis Association (B.T.A.) investigation, to be published shortly, into the incidence of aspergillus infection in "open healed" cavities has shown that the incidence is not negligible. In my own clinic, with approximately 1,000 patients on the tuberculosis register, we have 19 patients with "open healed" cavities, and no fewer than eight of these show evidence of aspergillus infection, six have a classical mycetoma demonstrated radiologically and have positive precipitin tests, and two have positive precipitin tests but so far no radiologically demonstrable mycetoma.

Resection in the presence of aspergillus infection is a more difficult and dangerous operation than resection in the absence of infection, and I submit that the likelihood of a young person left with such a cavity developing mycetoma in the future is sufficiently high to warrant resection of such residual cavities after adequate antituberculous chemotherapy, usually of two years' duration.—I am, etc.,

In Advance

SIR,—The correspondence on obstetric forceps or vacuum extractor (4 November, p. 292, and 11 November, p. 354) and on institutional care of the mentally subnormal (11 November, p. 355) reminds me of the

saying, "What Manchester thinks today London thinks tomorrow."

In the former, "the fact that it (the vacuum extractor) has largely replaced the forceps in several countries on the Continent" applies also to Northern Ireland and probably to other regions of the British Isles outside London.

In the latter, Northern Ireland for 10 years or more has cared for the mentally subnormal in the community with schools, and more recently with sheltered workshops and hostels.

Last month a swimming-pool exclusively for the use of the mentally subnormal was opened by Lady Wakehurst at Muckamore Abbey. Before this, hydrotherapy had been given at public swimming-baths, a treatment for the mentally subnormal which has been pioneered in Europe by Northern Ireland.

Several other advances in medical science have been instigated for the first time in the British Isles in Northern Ireland which I am reluctant to list for fear of appearing to boast. But the matters raised might indicate to your readers that here we appear to be in advance of, not behind, the times, and that the days of "pigs in the kitchen" have long passed away if they ever did exist.—I am, etc.,

Belfast 9.

MARY N. M. PAULIN.

North America Interview Board

SIR,—I would be grateful to be allowed to reply to the letters of Dr. J. Stanners and of Dr. C. D. H. Elton and Mr. I. W. M. Wright (18 November, p. 416).

The Interview Board's tour was arranged to meet the requests for interviews received in answer to the Ministry's advertisement of our visit published in the *B.M.J.* and other journals in July and August. Such requests were still reaching me when the Board left England on 30 September. At this time we had already invited 150 doctors to meet us for discussions of up to one hour each. It was possible to make only a few adjustments to this programme, because it was already very full and because the team's travelling schedule had to be adhered to. Every effort was made to accommodate doctors who approached the team at short notice, and where this was not possible informal meetings with individual members of the Board were arranged. I am sorry if some British doctors in Alberta were unaware of our visit before receiving a letter from the British Head of Post in Edmonton, but this, as I have said, was not the first intimation of our visit.

The Board would have gladly visited Edmonton if a sufficient number of doctors there had asked to meet us, but the centres chosen were necessarily locations which suited the convenience of the majority of doctors who had replied to the Board's advertisements. We sincerely regret that some of the doctors who approached us at very short notice could not be seen; this happened only where the Board's time was entirely taken up with appointments already arranged and confirmed.—I am, etc.,

R. H. BARRETT,

Chairman,
Interview Board, Ministry of Health.
London S.E.1.

Government-owned Health Centres

SIR,—It would appear that in the near future general practice will be conducted from well-equipped Government-owned health centres which will provide ancillary and laboratory facilities. At any rate I find that most of my colleagues are of the opinion that this transformation is in the natural process of the evolution of general practice, and that it is coming whether we like it or not. In fact it would also appear that the majority of general practitioners do like it. What is in no doubt at all is that the Government is keen on the idea and is offering financial inducements to general practitioners to form groups and go into health centres. Personally I am unable to view these inducements without a certain amount of misgiving—*timeo Danaos et dona ferentes*.

Nevertheless, I also feel that the "new general practice" is going to be a fact in a very few years from now, and that a salaried service will quickly follow. To my mind this change represents a possible threat to what is left of our independence and at the same time a possible chance to raise the status of family medicine and those who are expert in its practice. At worst, we can passively acquiesce to a take-over bid by a cynical Government aided by a handful of power-hungry medical politicians, in which case we shall have lost what little independence we have left, and our status will have become even lower than at present. At best, we can react in such a way to these imminent changes as to direct them towards the formation of a better type of general practice to the benefit of our patients and ourselves alike. I suggest that it would be worth our while to sacrifice a measure of independence (and this seems inevitable) for a career structure wherein an able doctor who had devoted eight to ten years of his life to general practice could expect to attain the rank of consultant (in family medicine) with the same pay, pension, and opportunity to win a merit award as his colleagues in the hospital service. It is quite unthinkable that we should be content to accept anything less than this. I would point out that there is nothing in the least inappropriate or even novel in this idea. The Indian Medical Service made the appointment of "Specialist in Family Medicine," which carried the same rank, pay, and kudos as any other specialty.

I also think that such a career structure would attract many of the best young doctors into family medicine—which could and should be the most rewarding of all the branches of our art.—I am, etc.,

Belfast 5.

J. D. H. MAHONY.

Practice "Twinning" Arrangements

SIR,—The health centre age is upon us, but what of those patients, those practitioners, and those areas where single-handed practice will continue to be a satisfactory, practical, and, in the case of country practice, an essential way of life.

Single-handed practice in future will be possible, and practicable, only if an efficient, reliable locum service is set up. Fewer and fewer young doctors, not forgetting their wives, will want to go to areas where they are isolated in terms of colleague contact and where in their isolation they are unable to

get time off for leisure, holidays, study, and illness. A patchy, unpredictable, sometimes unreliable and often absent locum service, as at present, will not do, as some areas will soon find to their cost.

I would like to suggest that consideration should be given to practice "twinning" arrangements whereby country doctors should be "twinning" with group practices in towns, even although these might be many miles away. The arrangement would cost little or nothing, but payment would be a problem, unless from central funds. Perhaps the Minister might be persuaded to put up a retainer for the involved parties. "Twinning" arrangements would allow country doctors to have freedom from the worry of personal illness and locum cover for holidays. Study courses could be regularly attended at the great teaching centres, and the country doctor could also, from time to time, work at the group practice with which he was "twinning," thereby having colleague contact which would be interesting, instructive, and stimulating for all concerned. Not all doctors in a group might wish to be available, and indeed not all might be suitable for what would be involved in taking over and running a single-handed country practice, sometimes at short notice in the case of illness. Experienced general practitioners in their forties would be best suited, and by repeated contact could get to know the particular practice well, and vice versa. How stimulating it would be for town general practitioners to practise real medicine occasionally in isolated country practice, especially if a cottage hospital was available.

Arrangements could be by mutual agreement and personal contact. Many single-handed doctors with doubts about the future of their practice might well be heartened by knowing that they were not alone and that a telephone call would bring a known, reliable, experienced colleague whose own work could be covered by his partners, helped by the local locum service of retired practitioners or retrained married women doctors, who would simply be required to help with the work at peak times and not have the considerable worry and responsibility of actually running the practice.

As a partner in a group practice I would welcome and be happy to participate in a properly organized practice twinning arrangement.—I am, etc.,

Musselburgh,
Midlothian.

CLIFFORD C. LUTTON.

"Mediflash"

SIR,—The "Mediflash" medical emergency light appears to be the subject of police criticism at present, and unless someone defends the scheme the authorities may well conclude that doctors do not care about being held up in traffic, so may I as originator of the design adopted by the B.M.A. comment on a few of the points in question?

In a letter to the B.M.A. (*Supplement*, 11 November, p. 50) the Chief Commissioner of the Metropolitan Police deprecates the use of the scheme because "... any further proliferation of flashing lights is bound to detract from the effectiveness of those that are already fitted to vehicles belonging to the fire, ambulance, and police services." This would be acceptable perhaps if the light was blue, but as it makes use of a different colour

surely this scheme cannot detract from the effectiveness of the blue light any more than the amber flashing lights permitted on vehicles such as gas works vans. Also, unlike the amber lights which are a permanent attachment, the green light will be seen only when required. Has not a doctor going to an emergency involving life a greater claim for this type of vehicle purpose identification than, for instance, a motoring organization's van attending a member's punctured car tyre? The letter also mentions that there may be no benefit without an audible warning device; the ordinary car horn, though not distinctive, will effectively draw attention to the flashing green light, which is.

A letter (18 November, p. 423) draws attention to the fact that the self-adhesive "Doctor-Emergency Duty" signs are "... almost invisible beyond the car's bonnet." Is this not strictly comparable to the abandonment of the old "Ambulance-Accident" sign in favour of the instantly recognizable symbol of the blue light, and should not doctors follow this example and adopt a symbol? If the doctor can be seen and helped by the police and motorists he can save much valuable time in difficult traffic, as compared with a small saving from just speeding in light traffic. Certainly the idea has been welcomed by the drivers of all three emergency services that I have spoken to, especially in the example of a doctor who when called to a bad road accident is readily visible to those already at the scene and to those motorists held up by the accident who have to be passed. This was confirmed when it was reported in the *Daily Mail* on 7 November that the medical officer in charge of the Lewisham Hospital major accident scheme (Hither Green rail disaster) was delayed by traffic and by police who had no means of knowing his identity until they had stopped his car and spoken to him. This resulted in a journey time to the control centre of over 30 minutes instead of the usual 15, and resulted in the first ambulance reaching the hospital with patients from the accident over 12 minutes before the arrival of the controlling medical officer.

If the profession is not allowed official recognition on the road then as traffic density problems increase so will delay times and the Documenta Geigy book on road accidents¹ confirms my own observations that delay in treating some emergencies can have very serious consequences. Granted these emergencies are not everyday occurrences, but this does not make them any less important when they arise.

If the green-light scheme is allowed to be quietly extinguished the parking badge will almost certainly suffer the same fate, and the doctor will then have no recognition at all even when dealing with a really urgent emergency.—I am, etc.,

Dunkerton,
Nr. Bath, Somerset.

R. SNOOK.

Prospects for Hospital Doctors

SIR,—I was glad to see Dr. E. A. Harvey-Smith (11 November, p. 359) drawing attention to the failure of the consultant establishment to expand as it should.

I was puzzled, however, by his penultimate paragraph, in which he says, "... I am assured that the Central Advisory Committee on Consultant Establishments never turns down a needed consultant post. . . ." From this he draws the conclusion that either hospitals are not asking for them, or boards are failing to forward requests that are made. This is at variance with our experience in Chelmsford. The anaesthetic department, the medical advisory committee, the hospital management committee, and the regional board all agreed in February 1966 that another maximum part-time consultant anaesthetist was needed, but this has been twice turned down by the Ministry of Health.

Perhaps Dr. Harvey-Smith can tell us by whom he was assured that this does not happen; or perhaps it all depends on the Ministry's interpretation of "needed consultant post."—I am, etc.,

Chelmsford,
Essex.

D. A. WALMSLEY.

Seniority Payments

SIR,—I refer to the "Eligibility in Seniority Payments" being tied to the "stipulated average numbers of sessions per annum of approved postgraduate training." I strongly object to this provision on grounds of principle and practicability.

I have a 3,000-list single-handed practice in this designated area, with a high percentage of immigrants and over 65s, and qualify for maximum seniority payment. I have four morning and evening surgery sessions, plus two morning-only (each of 1½ hours) and two afternoon maternity sessions. I do only N.H.S. work and I find myself fully occupied in coping with this, my relaxation being one half-day away (from 3 p.m.) per week, and an hour's rest in the afternoons. I have for several years also had an annual two weeks' holiday. I may add that I find it pays me to visit on a Sunday morning, which I almost always do. Thus in practice I find that the only times I am not regularly occupied are Saturday afternoon and evening and Sundays, and, apart from the question of needing time for a break for health reasons, I find it difficult to pick out postgraduate training sessions to fit in with these periods. A further and by no means theoretical point is that I would be in breach of my contract with the executive council by attending these sessions, the majority of which are at a distance where I would not be readily available for possible calls.

On the principle involved, it seems clear that there should be no strings attached to a payment factor of this kind, especially those of a harassing nature. My case and views must be typical of many, and I should welcome the comments of others. I urge our negotiators to take up the cudgels again even at this late hour.—I am, etc.,

Wolverhampton, Staffs.

S. STOWE.

REFERENCE

¹ *Statement of Fees and Allowances payable to General Medical Practitioners in England and Wales, 1966.* Ministry of Health.

SIR,—Doctors who qualified in 1953 find themselves the first to have to fulfil the new regulations involving provisional registration for one year before full registration.

Next year these doctors will find that though they have been qualified for 15 years they are ineligible for seniority award, as the "New Deal" has based seniority on the number of years since full registration, not since qualification.¹ This must seem strange to us all, as their colleagues who qualified in 1952 have received payment for seniority *this year*. To rub salt into their wounds a large percentage of these doctors have been disallowed vocational awards, as their two years' National Service, compulsory in 1953, is not considered adequate enough experience. Either our negotiators are unaware of these glaring defects in our contract, in which case they are incompetent, or they have sacrificed considerable sums of money to the Ministry at the expense of the younger doctors for some motive which is beyond my comprehension. I cannot believe that the Review Body intended different sets of values for doctors qualifying before and after 1953.—I am, etc.,

Edgware,
Middx.

A. B. DAVID.

Improving General Practice

SIR,—The revisions of the last Charter¹ were designed to stimulate the provision of improved medical services under improved working conditions. As part of this policy group practice was encouraged. There is, however, an anomaly in this respect in the provisions relating to the reimbursement for the cost of a locum during sickness. At present this reimbursement will be given only if the average list size of the remaining partners is 4,000 or more. Thus a two-man partnership with an average list of 2,000 would be reimbursed for a locum, but a three-man partnership with an average list of 2,000 would not be reimbursed. In other words, the larger the group the more difficult for it to obtain financial help in this respect. One appreciates that the larger the group the easier it is for it to absorb the extra work occasioned by the incapacity of one partner. Nevertheless this is not in line with the general principles of the Charter to improve the standard of general practice.

I hope that this anomaly will be reconsidered by the next Review Body.—I am, etc.,

London N.W.10.

PETER G. BRENT.

First Fellows of the Royal College of General Practitioners

SIR,—I was amazed to see a list of the first Fellows of the Royal College of General Practitioners elected (25 November, p. 498).

I have not seen any definite strict criteria laid down, such as original published work, etc., concerning general practice in the regulations of the Royal College of General Practitioners for such an election to Fellowship. No doubt most of the names of the newly elected Fellows are very familiar to us members of the College mostly for their various committee activities. The Fellows elected may be very deserving general practi-

tioners, but surely it is invidious to elect some members as Fellows because of their various committee activities or on some suchlike assessment.

This once again emphasizes how right the majority of we general practitioners were to overwhelmingly reject and throw out for ever the merit awards for general practitioners as proposed by the Ministry of Health and at that time accepted by our negotiators.—I am, etc.,

Nottingham.

B. I. KOHLINSKY.

Christmas Gifts Fund Appeal

SIR,—I should like to remind your readers who have not yet responded to the president's appeal (7 October, p. 57) that it is our custom to distribute the gifts in good time for Christmas.

In view of the rising costs of even basic necessities, it is the wish of the committee that the amount of the Christmas gift cheque given to each regular beneficiary should be increased this year, and it is hoped that the response will be even more generous than in previous years.

Please send contributions marked "Christmas Gifts" to the Royal Medical Benevolent Fund, 24 King's Road, Wimbledon, London S.W.19, as soon as possible.—I am, etc.,

GEOFFREY H. BATEMAN,

Honorary Treasurer,
Royal Medical Benevolent Fund.

London S.W.19.

Points from Letters

Deterioration of Professional Relationships

Dr. L. T. NEWMAN (London N.W.6) writes: "... It is becoming increasingly common, when one has referred a patient for a consultant opinion, for a general practitioner to be in the embarrassing position of not having a report on which to comment for a considerable period of time, even allowing for all the vagaries of our postal service. There is furthermore the appalling delay which takes place when a patient has been referred to a hospital before the hospital writes to give the general practitioner a report. I frequently have patients attending the surgery and have to contact the hospital before I am able to carry out their recommendations. Occasionally, one's patients have returned home after an operation before one is aware of the fact that they were even admitted to hospital. Naturally, the relatives concerned think that we are either callous or disinterested if, during the interim, we have made no inquiries concerning the patient's welfare.

There are, of course, many consultants who are both courteous and efficient, but I am afraid that, with the passing of time, these will become the exception rather than the rule, and thus widen the schism between these two branches of our profession. . . .

Reprints: Who Should Pay?

Mr. E. D. RUSKIN (Medical Librarian, Butterworth Hospital, Michigan, U.S.A.) writes: Dr. S. E. Browne's reply (7 October, p. 57) to the question: "Reprints: who should pay?" poses the problem of doctors finding time to answer requests, but neglects the difficulty of photocopying articles in journals that are so tightly bound (and lacking adequate margin-space) that at least a fraction of a page is lost in the process. Examples of this are the *B.M.J.* and the *New England Journal of Medicine*, both of which ought to consider reform—for the sake of the librarian who has to photocopy articles in bound volumes of them. . . .

Obituary Notices

G. H. BUCKLEY, M.B., CH.B., F.R.C.S.ED., F.R.C.S., J.P.

Mr. G. H. Buckley, formerly senior consultant surgeon to the Blackpool and Fylde hospital group, died at his home in Lytham on 17 November after a short illness. He was 71.

George Holden Buckley, son of a doctor, was born in Poulton-le-Fylde on 3 February 1896, and was educated at Blackpool

Grammar School and Manchester University. His medical studies were interrupted by the first world war, during which he served in the Royal Engineers. After demobilization he resumed his studies, and graduated M.B., Ch.B. in 1921. After holding junior appoint-

ments in the Manchester Royal Infirmary he took the F.R.C.S.ED. in 1925. He was greatly pleased by his election to the Fellowship of the Royal College of Surgeons of England, *ad eundem*, in 1949.

He joined the staff of the old Victoria Hospital, Blackpool—which at that time was virtually a cottage hospital—as an honorary consulting surgeon in 1927, and when he retired in 1961 he had been for a number of years the senior consulting surgeon to the Blackpool and Fylde hospital group. A superb technical surgeon, he devoted himself to raising the standard of surgery that then

prevailed in the provinces, and it is very largely due to his foresight, and to that of a few friends he gathered round him, that the Victoria Hospital has developed on its present site into the large specialist hospital that it is today.

Among his many activities, he was a Fellow of the Association of Surgeons of Great Britain, and was both a member and a past-president of the Provincial Surgical Club, with which he travelled widely. He was an original member of the Central Consultants and Specialists Committee which negotiated the terms of the National Health Services Act. He took a lively interest in the activities of the Blackpool and Fylde Division of the British Medical Association, and was chairman in 1938–9. He served throughout his active life on the Board of Management and after 1948 on the Hospital Management Committee of the Victoria Hospital, Blackpool, where his portrait now hangs in a position of honour as a tribute to his unique contribution to its progress over the years. In spite of the demands of a large consulting practice, he contrived to serve the community in other ways. He was appointed a magistrate in 1950, and on moving his home to Lytham St. Annes some ten years ago he began a new interest in local government and became chairman of the local health committee.

In 1928 he married Miss Eileen Heyworth, of Rossall Beach, who survives him. The deep sympathy of George Buckley's many friends and past patients will be extended to her and to her son and daughter in their sad loss.—D. K. L.

O. A. TROWELL, M.A., M.D., F.R.S.ED.

Dr. O. A. Trowell, an internationally distinguished senior member of the scientific staff of the Medical Research Council Radiobiological Research Unit at Harwell, died on 17 November. He was 58.

Oswald Arthur Trowell was born on 19 May 1909, and received his early education at King Edward VI School, Birmingham, and went to St. John's College, Cambridge, as an open exhibitioner in 1926. He became a scholar in 1928,

and obtained first-class honours in both parts of the natural sciences tripos. He did his clinical studies at Birmingham, and graduated M.B., B.Chir. in 1933. He proceeded M.D. in 1940, and was awarded the Raymond Horton-Smith prize for the best thesis of the year. He became a demonstrator in physiology at Liverpool, but in 1934 returned to

Cambridge. He was elected a Fellow of St. John's College, and later became director of medical studies. During the second world war he was lecturer in physiology in Edinburgh. From 1946 to 1948 he was reader in physiology at Bristol. During these years he soon gained recognition as an exceptionally lucid teacher of physiology.

In 1935 he published his first independent work in a paper on choline and liver respiration. This was followed in 1942 by a study of urea formation in the isolated perfused liver of the rat, and in 1946 by one on watery vacuolation of the liver, which is a classic. In these papers is ample evidence of the original approach, scrupulous attention to detail, and clarity of purpose which characterized all his later work.

In 1948 he embarked on a full-time career in research at Harwell at the comparatively late age of 39, and devoted himself to developing a method of maintaining lymph nodes for several days *in vitro* on a chemically defined medium. The method evolved had features in common with classical tissue culture technique and short-term methods for tissue slices. It is now widely used for many organs besides lymph nodes.

Being able to maintain lymph nodes *in vitro* enabled him to produce a formidable series of fundamental studies on the effects of x rays and numerous other agents on lymphocytes. The last of these studies was devoted to ultrastructural changes. His interests were by no means confined to lymphocytes, and he collaborated with others on papers dealing with subjects as diverse as the retina, the diaphragm, and the salivary glands. He also found time to write a review on the lymphocyte for the *International Review of Cytology* in 1958, and contributed several chapters to *Cells and Tissues in Culture*, which appeared in 1964–6. These are particularly valuable because of his clear, fluent style and complete mastery of the subject.

Despite his exceptional gifts, Ossie was a modest man. Behind his reserved, almost austere, demeanour he had a warm generous nature and a delightful dry wit. His personality was reflected in the happy atmosphere which prevailed in his laboratory; he was much loved by his staff. He was always ready to welcome to his laboratory the many other research workers who sought his advice, and he never grudged the time spent in giving help and advice—advice that was always sound and constructive.

Outside his work his tastes were simple and his interests wide. He was a talented artist with brush, pen, and pencil, and an expert gardener. Occasionally his scientific outlook intruded in his hobbies, as when he compared the "compost value" of the *Lancet* and the *Economist*. He was a great naturalist, and enjoyed an encyclopaedic knowledge of wild flowers and birds.

At home he was devoted to his family, and it is appropriate to conclude with a tribute to his wife, whose tireless love and patience helped him endure the distressing illness which marred the last year of his life. Our sympathy goes out to her and their two sons, the younger of whom recently qualified in medicine.—D. R. L.

E. N. W. writes: Trowell, whom I first met as a distinguished third-year student in physiology in 1929, joined Jacoby and myself in studies on fibroblastic growth in 1934, and we had a very fruitful triumvirate till Jacoby went to Birmingham three years later. Trowell stayed on for another year or two, and we worked together on the effects of tissue extracts on growth. He combined penetrating analytical powers with great technical skill and a scrupulous attention to detail. The minute and the precise fascinated him. He was an exceptionally clear teacher and writer, and took endless trouble to help his students. He was gloriously outspoken, and even his best friends were not spared the caustic edge of his tongue. While the latter knew that his bark was infinitely worse than his bite, unfortunately those who knew him less well were often put off by this mannerism. In fact, he was one of the gentlest and kindest people I have known. He had a very well developed sense of right and wrong, and would not tolerate humbug.

He had a delightfully pungent sense of humour, with a predilection for sophisticated puns, double meanings, and for the exploitation of the pompous and ridiculous. His letters were masterpieces of literary humour, and were often enlivened by highly skilful and apposite illustrations executed with a fine economy of line.

We had many interests in common. He and I constructed a rock garden together at his house in Cambridge. Bird-watching and indeed natural history in general were constant pleasures to him. Painting and drawing, too, held his attention for a time, and he brought to all these hobbies the same skill and precision that he gave to his scientific work. His death will be greatly mourned by his many friends, both at home and abroad.

DOROTHY C. HARE, C.B.E., M.D.
F.R.C.P., D.P.H.

Dr. Dorothy C. Hare, a former consulting physician to the Royal Free Hospital and Elizabeth Garrett Anderson Hospital, died on 19 November, at the age of 91.

Dorothy Christian Hare, daughter of Edward Hare, C.S.I., deputy inspector-general of hospitals in the Indian Medical Service, was born at Bath on 14 September 1876. She was educated at Cheltenham Ladies' College and the London School of Medicine for Women (now the Royal Free Hospital), graduating M.B., B.S. in 1905 and proceeding M.D. three years later. After holding early hospital appointments, she entered general practice at Cambridge in 1910, and in 1912 she took the D.P.H. She left her practice during the first world war and rendered distinguished service, first in Malta where in 1916-7 she was attached to the R.A.M.C., and later as medical director of the Women's Royal Naval Service in 1918-9. In recognition of these valuable services she was appointed C.B.E. in 1919. She took the M.R.C.P. in 1920, and the following year was appointed medical registrar at the Royal Free Hospital, later becoming assistant physician, and eventually consultant, to the Royal Free and Elizabeth Garrett Anderson Hospitals. She was elected F.R.C.P. in 1936.

Dr. Hare was a past-president of the section of therapeutics of the Royal Society of Medicine. She was the author of *Simple Instructions for Diabetic Patients*, which appeared in 1933.

Dr. Lilia Blackett Jeffries writes: When I reached the Royal Free Hospital—along with the first sizable group of women medical students following the pioneers—in 1905-6, Dorothy Hare was a house physician. She very quickly attracted our notice, partly for the sculptural correctness of her features, then for her calm and impressively confident manner, her obvious intellectual ability, and finally for the respect with which her chief treated her. She had a fine voice and gave a great deal of pleasure by her singing. None of her contemporaries were surprised by the professional honours she earned, and the recognition awarded her from her war service and public services. Many of us remember her guidance and help with gratitude.

W. BEAUMONT, M.R.C.S., L.R.C.P.

Dr. W. Beaumont, honorary consultant in physical medicine to the Westminster Hospital, died at the hospital on 14 November. He was 75.

William Beaumont was born in Huddersfield on 16 April 1892, and received his early education at Spring Grove Council School. He entered the London Hospital Medical College in October 1914. His studies were interrupted by the first world war, during which he served with the Royal Naval Volunteer Reserve. After demobilization he returned to the London Hospital, qualifying with the Conjoint diploma in 1922. He was house-surgeon to the ear, nose, and throat department at the London Hospital, and surgical registrar at the Throat Hospital, Golden Square. Subsequently he became interested in electrotherapy, and this was in the days when pyogenic infection was treated by rest, heat, and surgical drainage; surgical tuberculosis by rest and ultraviolet light; and wasted muscles by electrical stimulation. He soon became recognized as an authority on electrotherapy, and was one of the first medical examiners to the Chartered Society of Massage and Medical Gymnastics (now the Chartered Society of Physiotherapy). He published *Fundamental Principles of Ray Therapy* in 1931, *Diathermy* in 1939, and *Infra-red Irradiation*, which reached its third edition in 1951. During the second world war he served as a medical officer in the Emergency Medical Service.

Beaumont was instrumental in the establishment and became the first director of the Institute of Ray Therapy (now the Medical Rehabilitation Centre) at Camden Town, London. He was appointed consultant in physical medicine to the Westminster Hospital and to the Manor House Industrial Orthopaedic Hospital. He was a founder member of the British Association of Physical Medicine, in which he maintained an active interest after he had retired from hospital practice.

He leaves a widow and a son, to whom we extend our deepest sympathy.—F. S. C.

CHRISTINA B. BUCHANAN, M.B.
CH.B.

Dr. Christina B. Buchanan, a former consultant bacteriologist at the Royal Infirmary, Glasgow, died on 15 October after a short illness. She was 74.

Christina Blair Buchanan was born in Glasgow on 22 April 1893, and was educated at the Girls' High School and Glasgow University, graduating M.B., Ch.B. in 1916. After an appointment as medical officer at Ruchill Fever Hospital, she became assistant bacteriologist in the City of Glasgow Public Health Laboratory under Dr. R. M. Buchanan. She was later appointed assistant bacteriologist to Glasgow Royal Infirmary, where she reached consultant status. She also had a long association with the Federation of University Women.

Dr. Buchanan had a pleasant personality, and was very popular with a large circle of friends and colleagues, by whom she will be greatly missed.—M. H. M.

J. C. DICK, M.D., F.R.C.P. GLASG.
F.C.PATH.

J. R. McD. writes: As commanding officer of 19th General Hospital in the Suez Canal Zone I had the privilege of having John Dick (obituary, 4 November, p. 301) as pathologist in my hospital. I remember him with gratitude for three special reasons. When I went to the Middle East I knew very little about tropical medicine. John taught me all I know. Secondly, all German casualties came to our hospital, where we had 1,000 beds for them and a German staff, which included 13 German medical officers. It was almost self-sufficient, but despite repeated attempts we were unable to create a satisfactory pathology department. John solved the problem by accepting all their specimens in his own department. Thirdly, by his scrupulous care he established a department that was recognized by all as the "temple of truth."

F. A. PICKWORTH, B.SC., M.B., B.S.

Mr. W. STIRK ADAMS writes: I would like to offer my tribute to the memory of my old colleague and friend, Dr. F. A. Pickworth (obituary, 11 November, p. 363). In 1923 he joined Sir Frederick Mott as assistant pathologist to the Rubery and Hollymoor Mental Hospitals in Birmingham, and succeeded him as pathologist and director of pathological research in 1926. This research programme was sponsored after the first world war by Dr. T. C. Graves, F.R.C.S., medical superintendent, Sir Gilbert Barling, Pro-Chancellor of the University of Birmingham, and Sir Frederick Mott, who was in charge of the pathological services there after his retirement from London. Initially, under Sir Frederick's guidance, the special pathological investigation was directed to abnormalities present in the thyroid gland in the cadaver, and changes in its secretion. Later, similar studies were directed to possible abnormalities in the pituitary gland, which was excised with surrounding bone. Macroscopic evidence of chronic sphenoidal sinus infection and penetration by bacterial organisms into the surrounding bone and the brain stem was found in 24% of cases.

As a result of this finding a continuing clinical study of infections in the accessory nasal sinuses was made, and its extent recorded among the various types of mental disorder in the certified population of the hospitals. These investigations were carried out in every case under general anaesthesia. The recovery rate in these patients with certified mental disorders was found to be 10% better than the recovery rate published by any other hospital accepting similar cases, and this figure was maintained over many years.

Dr. Pickworth was an outstanding member of the team from 1923 to 1954, and by his continuing laboratory investigations he proved an essential guide in the clinical work, adding to its prestige. He also published numerous scientific articles, and later a summary of the pathological aspect of infective mental disorder in a *New Outlook on Mental Disease* (1955). Throughout he was a happy and friendly colleague and a loyal friend.

News and Notes

EPIDEMIOLOGY

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of scarlet fever and whooping-cough in England and Wales. Figures for

1967 are compared with the highest and lowest figures for each week in the previous

years shown. Areas where numbers of notifications were high in the latest two weeks for which figures are available.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending 11 November (No. 45) and corresponding week 1966.

Figures of cases are for the countries shown and for Greater London. Figures of deaths and births are for the whole of England and Wales (London included), Greater London, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES	1967					1966

MOTORING

Progress of the Wankel Rotary Engine

[FROM OUR MOTORING CORRESPONDENT]

Sooner or later it seems possible that some form of rotary power unit will supplant the reciprocating engine for motor-car propulsion. The most prominent contender in this field is the ingenious engine designed by Dr. Wankel, which has been the subject of a tremendous amount of research and development during the past 10 years—initially by N.S.U. Motorenwerke and more recently by Mercedes, Citroën, Curtis-Wright, Toyo Kogyo, and other companies.

N.S.U. were first in the field with a rotary-engined car for sale to the public in limited numbers. This had a Wankel engine with a single rotor, and in all some 2,500 cars were made. For the 1968 model year N.S.U. have announced a larger and much more ambitious front-drive car, designed to suit a twin-rotor Wankel engine, for which an output of 100 vehicles per day has been planned. Concurrently, the "Mazda Cosmo" sports model has been launched by Toyo Kogyo (in Japan) with a twin-rotor Wankel engine of their own design, based on six years of engineering development and testing.

Each of these projects ranks as a courageous, full-scale marketing evaluation of the technical and commercial merits of a power unit quite different in design from the reciprocating piston engine with which it competes. In fact the only principle in common is the thermodynamic operating cycle. In the car engines with which we are all familiar successive downward and upward strokes of each piston provide for the intake, compression, combustion, and exhaust of a mixture of petrol and air. The Wankel engine is a rotary machine, without pistons or valves, but the working cycle has four phases which correspond with those of the piston engine.

A photograph of the Mazda engine with an end cover removed shows the Wankel rotor and the curious "epitrochoidal" contour of the casing in which it turns (see Fig. 1). An eccentric shaft (not shown) adds the orbital motion to the rotation of the rotor, with the result that the three apex seals (S) make continuous rubbing contact with the curved inner surfaces. I should add that the sides of the rotor are flat and carry additional sealing devices which press against the ends of the "box" in which the rotor revolves.

Each of the three crescent-shaped chambers between the rotor and the casing alternately expand and contract in volume as the rotor turns. The one seen on the right is going through an expanding phase, in which a mixture of petrol and air enters through an intake port. A little later the continued movement of the rotor will close this port and the volume of the chamber will decrease, so providing the compression phase. This particular chamber will then occupy the position of the one seen at the top, where combustion is initiated by sparking plugs. As rotation continues the volume will first increase, completing the combustion or power phase, after which another port (not visible) is exposed to allow the exhaust gases to escape as the volume decreases again. The whole cycle is then repeated. Consequently, in each revolution of the rotor three charges of petrol and air are inspired, compressed, fired, and exhausted.

The unusual geometry of the engine requires that the eccentric shaft shall be geared to run at three times the speed of the rotor. Consequently, there is one firing impulse per shaft revolution in a single-rotor engine and two impulses in a twin-rotor design. If the volume displaced during each intake phase is,

for example, 500 c.c., a twin-rotor Wankel engine will burn 1,000 c.c. of mixture per shaft revolution, and is therefore equivalent in size to a four-stroke piston engine of 2,000 c.c. capacity. This is in fact the size to which both the N.S.U. and the Mazda engines approximate, and each of them develops about 110 b.h.p.

The principal advantages of the Wankel rotary engine can be summarized as:

- (1) Smooth, continuous rotation replaces the "stop-go" characteristics of a reciprocating engine.
- (2) Number of working parts is greatly reduced.
- (3) Engine is unusually light and compact.

The latest N.S.U. engine, for example, weighs only 265 lb. with all accessories; an equivalent piston engine would probably weigh an extra 150 lb. This saving in weight, together with compact overall dimensions, enabled the N.S.U. designers to install the engine ahead of the front wheels with an overall economy in space.

Problems in Design

Unfortunately, the engine presents some difficult problems to offset the impressive list of advantages. These are concerned with the sealing system, combustion efficiency, and production costs. No engineering training is needed to appreciate the difficulty of designing durable and effective sealing devices to prevent gas leaks from occurring between one chamber and another, remembering the extreme differences in pressure and temperature that exist during the various phases of the working cycle.

The development of piston rings to their present high standards of gas sealing, oil con-

FIG. 1.—A Wankel engine with an end cover removed to show the three-cornered rotor and other mechanical details.

FIG. 2.—Typical reciprocating parts of a conventional engine (Jaguar) showing the three rings which provide a seal between the piston and cylinder.

tol, and durability has taken many years—and yet a springy circular ring is a simple device in comparison with the seals that must be fitted to the three longitudinal peaks, the flat ends, and the six corners of a Wankel rotor. Furthermore, the seal at each peak, or apex, presents only one line of defence, whereas three rings in series are usually fitted to a piston (see Fig. 2). Like piston rings, the Wankel seals are spring-loaded and must be lubricated in order to last for a reasonable mileage.

At the present time lubricant for the seals is provided by a metering pump which feeds oil into the fuel pump at a rate which varies according to engine speed and throttle opening. It has been claimed by N.S.U. that this system gives adequate seal lubrication in return for an oil consumption amounting to 1% of the fuel used; say 3,000 m.p.g. on oil for a car giving 30 m.p.g. on petrol. This is a higher oil consumption than in many piston engines, but is acceptable.

Casings are made of aluminium alloy, mainly for the reason that the good conduc-

tive properties of this metal help to lessen the temperature differences between the hot and cool sections of the engine. To provide the durable and smooth inner surface required for satisfactory sealing (and seal life) the interior of the casing is electroplated with a hard metal, such as chromium. This coating then has to be finished in a special grinding machine, which adds to the production costs.

Combustion is something of a problem because the shape of the chamber is largely predetermined by the geometry of the engine. In order to get regular firing and efficient burning at all speeds and loads, a dual carburation system has been found necessary. One part of the system has a restricted choke (and passage) which gives a sufficiently high gas speed for starting, idling, and light loads. A second and larger "channel" comes into action for full throttle operation. Latterly combustion problems have been accentuated by the legal restrictions on exhaust gas pollution which will come into force in the United States on 1 January next and which

will probably also apply, later on, in many other countries.

Two sparking plugs per rotor are used both by N.S.U. and by Mazda. The main reason is that the optimum position for the spark varies according to operating conditions. A second reason is the fact that the cycle of events in a Wankel engine provides no "rest period" for the plugs, so that failures occur more often than in piston engines.

Summing up, it would be rash at this stage to predict that the Wankel engine is destined to supersede piston engines. Much more will be known when service experience with thousands of rotary-engined cars (in private, inexpert hands) has been accumulated. The N.S.U. engineers also believe that, with further development, manufacturing costs will be reduced and may even turn out to be less than that of an equivalent piston engine.

It will be very interesting to follow the future progress of a design that has a great deal of merit but which also presents some formidable difficulties.

PARLIAMENT

Health Services Bill

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The Health Services and Public Health Bill, which the Government have introduced in the Commons (it was read a first time on 22 November) is an omnibus measure of 74 clauses, plus four schedules. Much of it is a collection of minor changes in health and welfare service administration that has accumulated on the Ministry shelves waiting the arrival of the rare legislative opportunity "Parliamentary Time" to be put right.

It does also, however, impose new powers and obligations on local authorities, and it introduces a new hospital designation.

"University Hospitals"

Clause 5 enables the Minister of Health to designate by order certain hospitals which provide teaching facilities as "university hospitals"—a designation which will be an alternative to that of "teaching hospital" under existing provisions. The hospital or group to be so designated will be those that provide, or are to provide, for a university "facilities for undergraduate or postgraduate clinical teaching." Such hospitals will be administered by hospital management committees and not boards of governors.

The Minister is enabled by clauses 1 and 2 to make accommodation in Health Service hospitals available for private patients, without the accommodation having to be especially set aside for the purpose. These facilities are to be available for "resident patients who undertake . . . to pay such charges" as the Minister may determine; and in so determining the Minister is authorized to classify hospitals and fix the charges to be made, making different charges for different accommodation, different services, and different circumstances. The clause retains the condition that the use of hospital accommodation

shall be determined by the urgency of the demand on it.

The power to fix charges for private non-resident patients, and for amenity beds, contained in clauses 2 and 4, is specifically attached to the Minister.

Local Authority Services

In the local authority services the Bill imposes on the authorities the duty of providing a domestic help service "on such a scale as is adequate for the needs of their area," and includes the provision of laundry facilities. It amends existing legislation by enabling midwives, health visitors, and nurses to attend patients elsewhere than in their own homes. Local authorities are also to be enabled to accommodate the elderly and the handicapped in registered homes run privately for profit, as well as in voluntary or local authority homes as at present.

Opticians, dentists, and pharmacists will be able under the new provisions to engage in private practice at health centres—there are new definitions of "dispensing" and "ophthalmic" opticians—on terms and conditions to be fixed by the Minister. The membership of executive councils is increased to 30 to include the general ophthalmic service now put on a permanent basis.

Questions in the Commons

Registration under Abortion Act

Dr. JOHN DUNWOODY (Falmouth and Camborne, Lab.) asked the Minister of Health on 27 November how many private nursing-homes had applied for forms to be registered under the Abortion Act 1967.

Mr. K. ROBINSON: I have had 100 applications, of which 89 are from private nursing-homes.

Sir JOHN GILMOUR (East Fife, Con.) asked for similar information for Scotland.

Mr. W. ROSS: So far applications have been received from five establishments, of which two are in the county of Stirling and one each in Edinburgh, Dundee, and the county of Dumfries. These applications have not yet been considered.

Doctor-Patient Ratio

Mr. A. BUCHANAN-SMITH (North Angus and Mearns, Con.) asked the Minister of Health if he would state the ratio of patients to general practitioners in 1967.

Mr. ROBINSON: Final figures are not yet available, but the estimated average number of patients on the lists of doctors providing full medical services in England and Wales on 1 October 1967 was 2,470. The true number of patients per doctor will be slightly smaller, since it is not possible to eliminate all duplicate entries from doctors' lists.

Mr. BUCHANAN-SMITH asked the Secretary of State for Scotland what was the number of doctors providing unrestricted general medical services in each of the past five years, and what was the average number of patients per doctor.

Mr. W. ROSS gave the following figures:

	Principals Providing Unrestricted General Medical Services	Estimated Average Number of Patients
1963	2,633	1,996
1964	2,656	2,005
1965	2,611	2,049
1966	2,573	2,083
1967	2,583	2,082

(The figures in the second column are inflated by up to 3%, since it is not possible to eliminate all duplicate entries from doctors' lists.)

MEDICAL NEWS

College of Pathologists

The College of Pathologists held its fourth annual general meeting on 22 November at the Royal College of Physicians, London. Dr. J. W. HOWIE, president, was in the chair. It was announced that the following had been re-elected honorary officers for the forthcoming year: Dr. J. W. HOWIE, *president*; Professor J. GOUGH and Professor N. H. MARTIN, *vice-presidents*; Professor T. CRAWFORD, *registrar*; and Dr. F. HAMPSON, *treasurer*.

In the afternoon Sir HANS KREBS, F.R.S., and Sir RUDOLPH PETERS, F.R.S., were admitted to the honorary fellowship of the College at a ceremony preceding the fourth Foundation Lecture, which was given by Professor R. R. A. COOMBS, F.R.S., his subject being immunopathology.

The annual dinner was held in the Royal College of Physicians the same evening. Sir HECTOR MACLENNAN proposed the toast of the College, to which the President responded. The toast of the guests was proposed by Professor N. H. MARTIN, and Sir HAROLD HIMSWORTH, F.R.S., expressed their thanks.

Brompton Hospital Extension

A new wing at the Brompton Hospital, London, was officially opened on 17 November by the MINISTER OF HEALTH. It houses a department of radiology, operating-theatre suite, cardiology department, and a paediatric unit, the cost of which is being met from the hospital's endowment fund. In his address the Minister referred to the discussions that were taking place about the future relationships between the Brompton Hospital, National Heart Hospital, Institute for Diseases of the Chest, and Institute of Cardiology. He was encouraged, he said, by the progress made on proposals for joint development. The extension has cost about £300,000.

Course in Basic Medical Sciences

A revision course in basic medical sciences will be held at Addenbrooke's Hospital, Cambridge. The course is intended mainly for anaesthetists preparing for the March 1968 primary F.F.A. R.C.S. examination, but others are welcome to attend. It will be held every Saturday from 30 December 1967 to 16 March 1968 and will consist of 60 lectures and demonstrations (anatomy and pathology, 11 each, pharmacology 16, and physiology 22). The fee for the course will be £20, which will include refreshments. Further details and programme may be obtained from the Secretary, Cambridge University Medical School, Tennis Court Road, Cambridge.

Importation of Carcinogenic Substances

An Order in Council prohibiting the importation into the United Kingdom of certain chemicals which can cause cancer and are used in the rubber, chemical, paint, and dye-stuffs industries was published last week. The chemicals are beta-naphthylamine, benzidine, 4-aminodiphenyl, 4-nitrodiphenyl and their salts and any substance or article containing any of these compounds. The order complements the carcinogenic substances regulations made in June prohibiting the manufacture and use of these chemicals in this country. Exemption from the prohibition may be granted when the material is to be used in medical or scientific research.

The order will come into operation on 9 December. (*Carcinogenic Substances (Prohibition of Importation) Order, S.I. 1967, No. 1675, H.M.S.O. 8d.*)

Irradiation of Food

The Advisory Committee on the Irradiation of Food (see *B.M.J.*, 27 May, p. 583) has prepared a memorandum outlining the functions of the committee and giving advice to those who seek any exemption from the regulations. Copies can be obtained from the Secretary to the Committee, Room D303, Division I.F.(B), Ministry of Health, Alexander Fleming House, London S.E.1.

N.Y. Recognition of British Graduates

The Secretary of the Board of Medical Examiners, New York, in reply to an inquiry about the recognition of British medical qualifications in New York State, makes the following observations:

"Each case of a British medical graduate is considered individually by the Board of Regents on the submission of completed petition forms. In certain instances in which there is evidence of advanced and extensive acceptable hospital training and in which the physician has obtained the F.R.C.S. of England, M.R.C.P. of London or Edinburgh, F.F.A. or the F.R.C., endorsement of the British registration may be considered by the Board of Regents.

"If a physician wishes to petition the Board of Regents for an evaluation of his education and training and a determination as to his eligibility for admission to the New York State medical licensing examination or to medical licensure, he should notify this office [State Education Department, Albany, New York 12224] giving the name of the medical school from which he graduated and the date of graduation. Instructions and appropriate forms will then be sent."

Singapore Academy of Medicine

The office-bearers of the Academy of Medicine at Singapore for the year 1967-8 are as follows: *master*, Professor K. S. RATNAM; *assistant master*, Dr. SEAH CHENG SIANG; *scribe*, Dr. LEE YONG KIAT; *bursar*, Mr. ROBERT C. K. LOH; *bedel*, Dr. CHEW CHIN HIN; *censors*, Lieut.-Col. CHOO JIM ENG, Mr. YAHYA COHEN, Dr. GWEE AH LENG, Dr. GEORGE TAY, and Dr. YEOW SEANG AUN.

Termination of Pregnancy

The Ministry of Health announces that applications for approval of premises for the termination of pregnancy should be made forthwith (see *B.M.J.*, 11 November, p. 368). It points out that if they are delayed, and the number is substantial, there may be difficulty in clearing them before the Abortion Act comes into operation.

Fellowships in Mental Research

The Mental Health Research Fund has announced the following awards: John Spedan Lewis Foundation Fellowship for Research into Psychosomatic Illness (£4,970) to Dr. ANDREW ZEALLEY, Royal Edinburgh Hospital, for study of the importance of anxiety in the cause and management of asthma; Brunner Fellowship for Research in Depression (£9,000) to Dr. BRENDA HERZBERG, Epsom, for study of the effects on emotional mood of certain forms of oral contraceptive pill; Mental Health Research Fund Senior Fellowship (£6,866) to Dr. JOHN OXBURY, Oxford, for study of the functions of the temporal lobe of the brain in relation to epilepsy.

People in the News

► Dr. JAMES PATTERSON has been appointed medical secretary of the Medical and Dental Defence Union of Scotland, Ltd. He will take up his duties on 1 February 1968.

Recent Publications

Current Medical Research: a reprint of the articles in the Medical Research Council's annual report April 1966 to March 1967. The articles review advances made in some of the subjects with which the Council is concerned, but the scope of the reviews is not confined to work sponsored by the Council. H.M.S.O., 8s. net.

British Hospitals—Home and Overseas (1967 edition), sponsored by the British Hospitals Export Council in association with the King's Fund Hospital Centre, demonstrates British achievement in hospital design, construction, and equipment. The volume, which is illustrated by numerous pictures and diagrams, is intended to be a source of reference for those concerned with the provision of hospital services anywhere in the world. It contains a bibliography. Published by Trafalgar Press Ltd., 29 Palace Street, London S.W.1, price £1 post free.

Therapeutic Diets in Hospitals: a nutritional guide for hospital caterers, published by King Edward's Hospital Fund for London, 14 Palace Court, London W.2, 8s. 6d. post free.

W.H.O. Guide to Ship Sanitation, by VINCENT B. LAMOUREUX, H.M.S.O., £1.

The Psychosomatic Disorders: a pamphlet published by the Mental Health Research Fund (38 Wigmore Street, London W.1), price 1s. 6d., plus 3d. postage.

Coming Events

Postgraduate Medicine, 1967 (T.V. Programme).—"Growth in Childhood," Scottish Television, 4 December (11.50 p.m.), repeat 6 December (1.10 p.m.). "Advances in Reconstructive Surgery," Tyne Tees Television, 5 December (1.15 p.m.), repeat 10 December (10.15 a.m.).

Hungarian Scientific and Technical Days in London.—13 December. Papers on "New System Cobalt Units" and "An Analysis of the Respiratory Function in Post-traumatic Failures." Tickets and full details from the London Chamber of Commerce (Inc.), 69 Cannon Street, London E.C.4.

Sheffield University Faculty of Medicine.—Course in dermatology for general practitioners, 1-5 April 1968. For details see advertisement on page xxix.

Societies and Lectures

For attending lectures marked ● a fee is charged or a ticket is required. Applications should be made first to the institution concerned.

Sunday, 3 December

INSTITUTE OF LARYNGOLOGY AND OTOLGY.—10.15 a.m., seminar for general practitioners by Mr. A. Radcliffe.

Monday, 4 December

BLAIR BELL RESEARCH SOCIETY.—At Royal College of Obstetricians and Gynaecologists, 5.30 p.m., ordinary meeting.

CHELMSFORD MEDICAL EDUCATION AND RESEARCH TRUST.—At Chelmsford Medical Academic Unit, London Road (grounds of Chelmsford and Essex Hospital), 5.30 p.m., clinical meeting.

INSTITUTE OF DERMATOLOGY.—4.30 p.m., Professor A. S. Breathnach: The Melanocyte and Langerhans Cell.

INSTITUTE OF DISEASES OF THE CHEST.—6.15 p.m., Dr. J. N. Pattinson: Acquired Pulmonary Stenosis.

INSTITUTE OF LARYNGOLOGY AND OTOLGY.—5.30 p.m., Professor I. Friedmann, Dr. D. A. Osborn, Dr. M. I. Wright: clinicopathological conference.

KINGSTON-UPON-THAMES MEDICAL CENTRE.—5.15 p.m., Dr. R. G. Chittam: Chromosomes—Methods of Study; 6.30 p.m., Dr. D. E. H. Tee: Cancer—Experimental Carcinogenesis. ●

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—8.30 p.m., FitzPatrick lecture by Dr. P. E. Thompson Hancock: Thomas Hodgkin, Physician and Philanthropist.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—5 p.m., Wade demonstration—I by Mr. A. A. Gunn: Surgical Pathology of the Gall Bladder.

ROYAL POSTGRADUATE MEDICAL SCHOOL.—At Wolfson Institute, 4 p.m., Dr. Roger Bannister: Investigation and Treatment of Idiopathic Orthostatic Hypotension.

SCOTTISH TELEVISION LTD.—11.45 p.m., Growth in Childhood. (Sponsored by Glasgow Postgraduate Medical Board.)

SOCIETY FOR MEDICAL AND DENTAL HYPNOSIS.—At Royal Society of Medicine, 8 p.m., clinical meeting, cases will be presented.

Tuesday, 5 December

B.B.C. 2 TELEVISION.—1.15 p.m., medicine today: Parkinsonism. (Sponsored by A.S.M.E.)

BOLTON AND DISTRICT MEDICAL SOCIETY.—At Gymnasium, Bolton Royal Infirmary, 8.15 p.m., medico-legal lecture by Dr. L. A. Liversedge: Some Neurological Problems.

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At Kennedy Lecture Theatre, Institute of Child Health, 5.30 p.m., Dr. E. T. O. Slater: The Genetics of Schizophrenia.

INSTITUTE OF DERMATOLOGY.—4.30 p.m., Dr. E. A. Cronin: Mechanism of Pigmentation and its Anomalies.

MANCHESTER MEDICAL SOCIETY: SECTION OF SURGERY.—At Large Anatomy Theatre, Manchester University Medical School, 5 p.m., Mr. A. B. Wallace: The Plastic Surgeon in Paediatrics. NORTHAMPTON GENERAL HOSPITAL.—8 p.m., Professor P. B. Beeson: General Considerations in Management of Infections.

ROYAL ARMY MEDICAL COLLEGE.—5 p.m., Professor

W. Linford Rees: Drug Addiction.

ROYAL COLLEGE OF GENERAL PRACTITIONERS: SOUTH LONDON FACULTY.—At General Practitioners Centre, St. Mary's Road, London S.E., 8.15 p.m., Dr. T. H. Bewley: Drug Addiction.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—5 p.m., Wade demonstration—II by Mr. A. A. Gunn: Surgical Pathology of the Gall Bladder.

ROYAL POSTGRADUATE MEDICAL SCHOOL.—4 p.m., Mr. A. K. Monro: Tumours of the Colon.

St. CHARLES'S HOSPITAL MEDICAL CENTRE.—8.45 p.m., Dr. M. Feiwel: Dermatological Colour Slides.

WESTMINSTER MEDICAL SCHOOL.—At Keene Theatre, 5.15 p.m., Dr. J. G. B. Thurston: Intensive Coronary Care.

Wednesday, 6 December

BROOK GENERAL HOSPITAL.—8.15 p.m., neurology meeting with presentation of cases. Dr. D. Geraint James: Neurosarcoidosis.

CAMBRIDGE MEDICAL SOCIETY.—At University Arms Hotel, 7.30 p.m., supper meeting, Professor K. Simpson: Crime and the Doctor (illustrated).

CHELMSFORD MEDICAL EDUCATION AND RESEARCH TRUST.—At Chelmsford Medical Academic Unit, London Road (grounds of Chelmsford and Essex Hospital), 12 noon, surgical meeting.

INSTITUTE OF DERMATOLOGY.—4.30 p.m., Professor

F. A. Whitlock: Psychosomatic Disease—II.

INSTITUTE OF DISEASES OF THE CHEST.—5 p.m., Dr. R. V. Gibson: Clinical Assessment of Heart Disease.

New Issues of Specialist Journals

Obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London W.C.1.

ANNALS OF THE RHEUMATIC DISEASES

Contents of the November issue are as follows:

Rheumatoid Pleuritis. W. C. Walker and V. Wright.

Clinical Background of Rheumatoid Vascular Disease. M. Wilkinson and W. N. Torrance.

Lipid Content of Human Costal and Articular Cartilage. R. A. Stockwell.

A Clinical and Serological Study of Rheumatoid Arthritis. Mary Corbett, June M. Downes, and F. R. Schmid.

Mefenamic Acid in Rheumatoid Arthritis. A. B. Myles, P. A. Bacon, and K. A. Williams.

An Investigation of the Prevalence and Significance of Gastric Parietal-cell Autoantibody in Rheumatoid Arthritis. E. M. Armstrong.

Influence of Lymphatic Tissue on the Development of Adjuvant-Induced Polyarthritis in Rats. A. G. Ryzewski.

Ultrastructure of Synovial Membrane in Osteoarthritis. S. Roy.

Haemolytic Complement Level and Ragoocyte (R A Cell) Concentration in Synovial Fluid. A. P. Felder, F. Delbarre, and G. Krassinine.

Influence of Trauma on the Development of Chronic Inflammatory Polyarthritis. K. A. Williams and J. T. Scott.

Rheumatoid Arthritis of the Temporomandibular Joints. J. J. Marbach and H. Spiera.

Immunological Characterization of Some Basement Membrane Antigens. G. Loewi.

Nature of Anaemia in Rheumatoid Arthritis. VII. Storage of Iron in Rheumatoid Disease. A. A. H. Lawson, E. T. Owen, and A. G. Mowat.

Ibuprofen in the Treatment of Rheumatoid Arthritis and Osteoarthritis. P. L. Boardman, G. Nuki, and R. Dudley Hart.

Shakespeare's Rheumatology. G. E. Ehrlich.

Book Reviews. Icterden Society. Abstracts. Index, 1967.

Volume 26, No. 6. Yearly subscription (6 numbers) £4 4s., abroad £4 15s.

JOURNAL OF CLINICAL PATHOLOGY

Contents of the November issue are as follows:

Activation of Lymphocytes. R. J. V. Pulvertaft and Isobel Pulvertaft.

Lipofuscinosis of the Gastrointestinal Tract in Man. Bernard Fox.

Tracheopathia Osteoplastica. S. P. B. Way.

Acute Necrotic Alveolitis and Perivascular Encephalomyelitis Associated with Hypertension and Renal Infection. A. A. Miller and F. Ramsden.

Incidence and Significance of Argentaffin and Paneth Cells in Some Tumours of the Large Intestine. N. M. G. Hiss.

Significance and Interpretation of Laboratory Tests in Pulmonary Aspergillosis. Mary P. English and A. H. Henderson.

Further Observations on Inclusion-bearing Cells in Urinary Sediment in Infectious Diseases. J. F. Boyd and Nada Nedelkoska.

Granulomatous Giant Cell Reticulosis Associated with Cases of Treated Leukaemia. G. Krasznai, S. Keresztury, and L. Szűcs.

Platelet Adhesiveness in Diabetes Mellitus. S. Shaw, G. D. Pegrum, Sylvia Wolff, and W. L. Ashton.

Red Blood Cell Abnormalities in Cardiac Valvular Disease. J. Forshaw and L. Harwood.

Hyaline Droplet Formation in the Renal Epithelium of Patients with Haemoglobinuria. S. J. Bryant.

Hyaline Cast Formation in Patients Treated with Cephaloridine. W. D. Linsell, A. Pines, and J. W. Hayden.

Observations on the Levels of γ G, γ A, and γ M Globulins, Anti-A and Anti-B Agglutinins, and Antibodies to Escherichia coli in Down's Anomaly. M. Adinolfi, Brigitte Gardiner, and Wendy Martin.

Mycoplasmas and Recurrent Oral Ulceration. A. M. Gordon, H. M. Dick, D. K. Mason, W. Manderson, and W. R. Crichton.

Resistance to Cloxacillin Among Hospital Staphylococci. G. C. Turner and P. E. Cox.

Serological Diagnosis of Amoebiasis by Immunofluorescence. Somnate Boonpucknavig and R. C. Nairn.

Evaluation of the Fluorescent Antibody Technique for the Diagnosis of Smallpox. A. L. A. El-Ganzoury.

Fatal Transfusion Reaction Due to Serratia marcescens. W. A. Black, A. Pollock, and Elizabeth L. Batchelor.

Importance of Potency in Typing by Colicine Production. J. McGeachie and W. McCormick.

Young Disabled and Sick in Hospital

In 1959 the welfare of children in hospital was the subject of a report¹ by a Central Health Services Council committee under the chairmanship of Sir Harry Platt, and subsequently the Minister invited hospital authorities to act on its recommendations. On a date in 1964, and on a further date in 1965, hospital authorities took a census of patients aged under 17 in National Health Service hospitals in England and Wales to obtain information about children and adolescents in hospital. The census² showed to what extent hospital practice accorded with the recommendations of the Platt Committee, and it disclosed 22,047 children and adolescents in hospitals in 1964, and 22,350 in 1965—or 1.8 children and adolescents per 1,000 of the population under 17 years of age. Most of them were under 12, and the census showed that 5% were being nursed in adult wards without any separation, while a further 13% were in adult wards but separated from adult patients. One-third of the adolescents were nursed in children's hospitals or in children's wards, one-tenth in adult wards but separated, and well over half in adult wards without separation.

The Platt Committee had recommended that the ward sister should be a registered sick children's nurse as well as S.R.N., but the census showed that only about half of the young children were under the care of registered sick children's nurses. Again, the committee had recommended that a children's physician should have a general concern with the care of all children, but this practice was not by any means evident. Other examples could be mentioned of failure to implement recommendations of an expert committee which the Ministry of Health had "invited" hospital authorities to do.

A pilot survey³ carried out by the two geriatric physicians in Fife, R. Rankine and R. M. L. Weir, with the aid of a grant from the South-eastern Regional Hospital Board (Scotland), adds to our knowledge about the plight of the younger disabled and chronic sick. It covered a sample population of 30,000–35,000 persons (about 10% of the total population of the county), and the two physicians had the assistance of 14 general practitioners as well as the local health departments. The survey included people aged 15 to 60 years suffering from long-term physical illness or disability to the extent that they were unable to take part in the normal activities of daily living. It revealed 87 cases, or 2.63 per 1,000 population, the lowest rate being in a rural practice and the highest in a practice largely confined to one of the older mining communities. The sexes were equally affected, and the incidence increased with age. Multiple sclerosis was the most common disability, closely followed by rheumatoid arthritis, cerebrovascular disease, and chronic bronchitis. Only 5 of the 87 patients were in institutional care; the care of the remainder devolved increasingly on the parents, usually the mother.

The authors of this report suggest that unsatisfactory housing conditions were of little importance, though they were distressed at the number

of persons who might have been rehoused in ground-floor accommodation. The patients themselves thought that the interests of the family had to be recognized, and were determined to be as independent as possible. The authors conclude that the number of such persons under the age of 35 was small and that in almost every respect they fared better than their elders, particularly in terms of medical care and of opportunities for employment. They confirmed the statement in the Piercy Report⁴ that "doctors still need to be better informed of the scope, nature and potentialities of rehabilitation," and suggested that local authorities needed to know more about the chronic sick and disabled in their areas. They considered that a hospital unit of 60 beds should be adequate to serve the needs of a population of about 300,000.

It is difficult to determine precisely the size of the problem. The number of substantially and permanently handicapped people aged between 16 and 65 years in Great Britain at the end of 1964 on the registers of local authorities was 164,000. In 1963 the Ministry of Pensions and National Insurance recorded 225,800 people in Great Britain between the ages of 18 and 65 years (60 for women) who had been receiving sickness benefit for two years or more, with perhaps a further 100,000 sick or handicapped people of this age group in receipt of National Assistance allowances for the same period. There are thus, possibly, some 500,000 people of working age in Great Britain so handicapped as to be incapable of paid employment, though with the exclusion of mental illness and mental subnormality the estimate might fall to 370,000. The most unsatisfactory position relates to the thousands of young chronic sick patients, of whom perhaps only one-tenth are in special units designated for their care. Many of the remainder are scattered through geriatric wards. Though some of these are middle-aged, this is no excuse for a lack of interest and drive that is an unhappy reflection on our hospital service.

It is often said that many such patients prefer to be in hospital wards, however unsuitable, near their homes and former environment. But this is not always borne out by experience, for many of the excellent homes provided by voluntary organizations attract patients from all over the country, who soon adapt themselves to the new community in which they are placed. This type of patient often comes to the hospital service as a social emergency. Consequently there might well be established in each region a hospital unit, or units, for the young chronic sick which would provide not only a hospital ward with single and double rooms and cubicles but occupational rooms of sufficient variety to recognize that the patient is usually going to spend the remainder of his days in that hospital, and needs an environment appropriate to his condition and to his mental faculties and interests. Such units might be of 25-50 beds, and without doubt relatives and friends would not resent travel if they were satisfied by the better conditions for the patients. The unit for young chronic sick could be in the environs of the general hospital rather than in an isolated institution, and the patients should be in the clinical charge of a special physician. More needs to be done to arrange temporary admissions of patients for their own benefit and for the relief of relatives, and to organize holidays in a new setting.

These two reports merit careful study, and point the way to a more active policy to alleviate the lot of these unfortunate, but not always recognized, children and young and middle-aged people suffering from long-term disability and sickness.

Pulmonary Embolectomy

When Trendelenburg¹ first told of his method of removing pulmonary emboli his vision and daring were received with enthusiasm. Sadly, the patient's strength was rarely able to match the surgeon's skill, and only a few cases of emergency embolectomy were successful. The development of cardiac surgery and the heart-lung bypass machine brought a new understanding of the physiology and surgery of the heart, and the possibility of successful pulmonary embolectomy became real. Now all cardiac surgeons practise emergency embolectomy, most of them using the heart-lung bypass,²⁻⁴ but some good results have been achieved without it.⁵ It is no longer a question of whether an embolectomy can be done, but when is the right time to do it.

Pulmonary embolism presents in four ways: firstly, sudden death; secondly, collapse, hypotension, and right heart failure followed by death or slow recovery over a few hours; thirdly, sudden severe pain, haemoptysis, and collapse followed by a steady, sometimes rapid, cardiovascular recovery; and, fourthly, without clinical disturbance of the cardiovascular system.

In making the diagnosis the surgeon will in some cases note the clinical signs of peripheral vascular collapse, high central venous pressure, third heart sounds, characteristic changes in the E.C.G., and the absence of vascular markings on the chest radiograph. These are diagnostic if they are all present, but unfortunately many cases do not have these physical signs. Consequently some surgeons advocate doing a preoperative pulmonary angiogram to avoid operating on a coronary infarction—the main differential diagnosis. This takes time, as does lung scanning after the injection of labelled macroaggregates of albumin,⁶ and often there is no time to spare.

The approach to the management of the four clinical groups is slowly evolving along the following lines. Sudden death from pulmonary embolism should be treated by external cardiac massage, for in some cases the massage will break up the thrombus, move it on, and so allow some pulmonary blood flow. If the circulation is restored and the patient responds, then the massage is continued until the patient is anaesthetized and either put on a heart-lung bypass or given supportive perfusion with blood taken from the femoral vein, oxygenated, and returned to the arterial circulation. There is obviously no time to confirm the diagnosis before operation, and so it must be accepted that a certain number of these patients will

be found to have a normal pulmonary artery and an infarcted myocardium.

Those who collapse and remain very ill require surgical treatment, or possibly thrombolytic therapy.^{7,8} But there is usually time for diagnostic investigations,⁹ and emergency pulmonary angiography is of great help. Embolectomy can then be done, and this is the group of patients in whom the best results are obtained.¹⁰ It is difficult to decide when to operate, but failure to improve over one to three hours, with hypotension and a raised central venous pressure, are sound indications for surgery.

The third group, collapse followed by fairly rapid recovery, presents many problems. Though surgery is not needed to save life, two great risks threaten these patients. Firstly, there may be another embolus waiting in the legs which, added to the first, could kill (second emboli occur in 30% of patients).¹¹ Secondly, early cardiovascular recovery does not mean that the patient will ultimately attain normal health. D. Phear¹² has shown that 30% of patients who survive a major embolism have persistent and sometimes disabling dyspnoea, due either to the initial embolus or to recurrent small subclinical emboli. It seems reasonable to suggest that these patients should have their peripheral veins studied, as suggested by N. L. Browse and his colleagues (p. 596), and a pulmonary angiogram done, and then be considered for thrombolytic therapy or surgery. How much time is available for these investigations before the thrombus becomes so adherent that it is irremovable? The paper by Lord Brock and his colleagues published at page 598 of the *B.M.J.* this week sheds light on this question, for it shows that emboli can sometimes be removed months after impaction. Many cardiovascular surgeons have operated on pulmonary and peripheral arterial emboli after impaction and found some to be irremovable and others loose. More information is required about the natural history of emboli. Though they undergo lysis spontaneously and rapidly in the dog,¹³ there is ample clinical evidence to prove that this does not always happen in man. The increasing use of pulmonary embolectomy should expand our knowledge of the local lesion in the pulmonary artery.

The present trend is to be bold not only to save life but also to reduce the late morbidity. But this approach needs to be continually reviewed in accordance with the findings at operation and the long-term results.

Doctors' Diseases

In the evidence which the B.M.A. submitted to the Goodenough Committee it deplored the failure of the medical schools to exclude men and women who, though able to pass examinations, have not the requisite aptitude, character, or staying power for a medical career. The Committee agreed, and recommended¹ that there should be machinery not only to select students from this standpoint but also to weed out students who prove unsuitable. No one, however, was bold enough to state the criteria of rejection, or, more specifically, to say whether a propensity to some form of psychological illness should be regarded as a sign of unsuitability. Deans of medical schools might have very discrepant views on this matter, and on their ability to look sufficiently into the future of some nervous aspirant aged 18 or 19 to foretell his professional fitness or inadequacy. Nevertheless, the attempt has to be made, for the health and mental stability of doctors are matters of public as well as

private concern. It is therefore understandable that the authors² of a recent inquiry should express their surprise that there have been few studies of the amount of psychiatric illness in the medical profession. Their own findings are not particularly encouraging.

A hundred and ninety-two doctors who had been treated at either St. Andrew's Hospital, Northampton, or St. George's Hospital, London, were compared with "control" groups, presumably free from psychiatric illness. There were no differences between the doctors and non-medical patients (matched for age, sex, and social class) in the frequency of most sorts of disorder, except that neurotic depressive reactions and drug addiction were more common in doctors. Psychiatrically disturbed doctors showed a greater tendency than usual to fall by the wayside professionally; only 70% were on the *Medical Register* when followed up in 1964.

The proportions in which various branches of the profession were represented in the sample do not permit any simple conclusion to be drawn. General practitioners made up 53%, 12% were psychiatrists, and 11% were surgeons. A similar investigation³ of 93 doctors admitted to the Mayo Clinic for psychiatric treatment between 1956 and 1963 showed that 44 were general practitioners (about the same proportion as in the profession as a whole), 15 were physicians, 17 were surgeons, and 4 were psychiatrists. Evidently no single branch of the profession has a disproportionate pre-eminence in this respect. A third of the doctors had some form of psychotic illness, a fifth were neurotic, and most of the remainder had personality disorders. Treating them was exceptionally difficult because the doctors found it hard to accept the status of a patient and tended to withdraw from treatment too soon.

There are two aspects of psychiatric illness which are painfully prominent in this connexion—suicide and drug addiction. Analysis of the *Registrar General's Decennial Supplement* earlier in this century⁴ showed that among the occupational groups with the highest suicide rates were doctors and lawyers. It has been conjectured that this was because they "work under some degree of nervous pressure" and witness much misery and suffering. In a recent study⁵ in Oregon the suicide rate for doctors and lawyers was found to be three times as high as in "white-collar workers." Despite the known unreliability of official statistics of suicide, it must be regarded as an occupational disease of medical practice.⁶

The problem of addiction in doctors has also been long recognized. The Rolleston Departmental Committee⁷ that reported in 1926 said that "questions of exceptional difficulty have presented themselves in the cases of doctors who are themselves addicts," and the Brain Committee⁸ echoed this, pointing out that the number of doctors known to be addicts was disproportionately high. There were in Britain in 1960 68 "professional" addicts—doctors, dentists, pharmacists,

and veterinary surgeons—constituting 15% of the total number of known addicts. According to the report sent to the United Nations from the United Kingdom doctors made up 81% of all the known “professional addicts,” including nurses. As always where drug abuse is concerned, the number of officially known addicts is almost certainly a much lower figure than the real situation would disclose. M. F. A’Brook and his colleagues² had among their 192 patients 30 who were addicted to some drug other than alcohol.

In Germany³ there were in 1957 4,861 addicts, of whom 12% were doctors. One doctor in 112 was an addict. Reports from the United States deal for the most part with selected populations of doctors—those treated in private¹⁰ or in the special hospital for addicts at Lexington, Kentucky.¹¹ Many psychopathological explanations of the development of addiction in these doctors have emerged from the intensive study they received, but there can be little doubt that the most potent factor in giving them an unhappy pre-eminence among addicts has been the easy access to drugs (though this is not of course the only important factor). It is noteworthy in this connexion that in a study by J. L. Evans¹² of 50 doctors’ wives who received treatment in a private psychiatric hospital between 1960 and 1963 10 had overuse of drugs as their major presenting symptom, and 12 others had a history of overuse of addictive drugs (apart from alcohol). Fourteen of these 22 women had used morphine or morphine derivatives. Evans concludes that the addiction was related “dynamically and empirically to the profession of the husbands.” A number of the women had continued to have ready access to drugs after the addiction was evident.

Can nothing be done to reduce the numbers of doctors’ lives wasted by these occupational hazards? Too often, perhaps, colleagues who are aware that all is not well stand aside and refuse to interfere when early action is essential.

Arthritis and Sarcoidosis

Sarcoidosis is a widespread granulomatous process the signature of which is the sarcoid nodule. This is demonstrable by biopsy and sufficiently characteristic and uniform under the microscope to imply that sarcoidosis has a single cause, but the occurrence of an identical sarcoid reaction to beryllium disease and to some fungal infections proves otherwise. Beryllium disease and fungus infections of this type, however, are rare, and sarcoidosis without exposure to these agents is fairly common, so experts in the disease may be forgiven if they continue to write about sarcoidosis and not about the “sarcoidoses.” This apparently academic point is of practical importance in assessment of the prognosis of the condition and its associated manifestations such as arthritis.

A variety of quite different joint conditions have been described as associated with sarcoidosis. The value of studies of this kind is limited if several types of sarcoidosis are lumped together in the reported series. This is particularly so when the Kveim reaction (an artificially induced local sarcoid nodule) is used as proof of the disease. Statistics based on hospital studies are notoriously fallible when it comes to describing apparent association between diseases whose causes are unknown. The “two-disease fallacy” creeps in—the interesting possessor of two diseases is far more likely to be written about than the humdrum patient with only one. Epidemiological studies might be expected to help to clarify the association between arthritis and sarcoidosis, and a valuable survey has been reported by I. Sutherland, D. N.

Mitchell, and P. D’A. Hart, who looked for the development of sarcoidosis in a 14-year prospective follow-up study of 54,239 children and adolescents vaccinated against tuberculosis or observed as unvaccinated controls. They found 52 cases and mentioned that only three of them had joint pains. Nevertheless, workers in hospitals continue to find a high incidence of arthritis in histologically proved sarcoidosis, and in some patients this may be the presenting complaint.

The problem has been looked at both in rheumatism clinics (where the selection factor for arthritis is to be expected) and in specialized sarcoidosis clinics, as in a recent study by J. M. Gumpel and his colleagues.² If nonspecific or unrelated causes of joint symptoms are excluded at least three different presentations of arthritis emerge. The first, well-characterized, is an acute arthritis predominantly of the knees and ankles, occurring with or often before erythema nodosum. The characteristic patient is in the third or fourth decade and is more often a woman, and the associated clinical features include a painful oedema of the ankles and feet, marked and sometimes incapacitating stiffness of the limbs—especially in the mornings—fever, enlarged hilar lymph nodes, and general malaise. The response of the arthritis to corticosteroids is excellent and complete recovery is the rule, at least in Britain. Anergy to tuberculin and biopsy evidence of sarcoidosis in lymph nodes or other tissues in a small proportion of cases has led to this condition being classified as an arthritis of sarcoidosis, but neither the sarcoidosis nor the arthritis leaves any permanent residue. A positive Kveim test is common and by itself has been accepted as histological proof of sarcoidosis—for example, by Dr. D. G. James and his associates.³ Sutherland and his colleagues, however, thought that the Kveim positivity had “some immunological basis not directly related to sarcoidosis.” In other words, the presence of a positive Kveim test by itself should not be taken as histological proof of sarcoidosis. Many would feel that it would be preferable to regard this acute, early, and clinically distinct form of arthritis as no more than a part of the “erythema nodosum syndrome” and, as L. H. Truelove⁴ suggested, “as independent of the underlying cause of the syndrome, whether this be sarcoidosis, tuberculosis, or drug sensitivity.”

Two other forms of arthritis associated with sarcoidosis reflect the granulomatous invasion of the para-articular bone or of the synovium. They are much less common, much more likely to become chronic, and they are always associated with clinically apparent granuloma formation in the skin, lung parenchyma, eyes, lymph nodes, or peripheral nerves. Sarcoid dactylitis may give swollen painful fingers, which resemble rheumatoid arthritis superficially, but the radiograph will show the diffuse osteitis in the phalanges—an appearance which is seen much more frequently than the often quoted punched-out cysts. Synovial lesions⁵ may take the form of localized plaques of sarcoid-containing tissue, which replace part of the synovium and are associated with a nonspecific reaction elsewhere in the joints. The clinical course of such lesions is variable but usually takes the form of a subacute and recurrent hydrarthrosis. Both the arthritis

of the erythema nodosum syndrome and the arthritis of synovial sarcoid infiltration may precede the signs of illness elsewhere. Rheumatic fever, rheumatoid arthritis, and even of gout may be suggested diagnoses in this early phase and may on occasion be supported by nonspecific T-wave changes in the electrocardiogram⁶ or by positive tests for rheumatoid factor due to gammaglobulin changes⁷ or by elevation of the serum level of uric acid⁸ due to increased cell division. Isolated case reports have probably over-emphasized the importance of these instances of clinical overlap. Gumpel and his colleagues did not find that they were of much importance in practice.

Investigation of the Young Hypertensive

Despite intensive research into the aetiology of hypertension during the last two decades it is still unhappily true that only in some 10% of all hypertensive patients is it possible to identify a likely cause for their disease. Further, only in perhaps one-third of this 10% is it possible to cure or improve the hypertension by an operation on the kidney or adrenal glands. Nearly ten years ago Lord Platt¹ observed that the incidence of secondary hypertension was relatively high in patients under the age of 40 (in whom he reckoned only about 30% had primary or "essential" hypertension). Since then most physicians have adopted a conservative attitude to the investigation of hypertensive patients over the age of 40 but have continued to investigate their younger patients intensively. Everyone who does this has the occasional gratifying experience of curing a young hypertensive, but against every patient cured of his hypertension must be set the morbidity of renal investigations, especially aortography² and divided function studies, in the less fortunate remainder. As hypotensive drugs year by year become more effective and produce fewer side-effects the burden of lifelong treatment lessens and the necessity for surgical cure becomes less imperative.

From the Royal Postgraduate Medical School, A. Breckenridge and his colleagues³ have just reviewed their experiences in investigating intensively 229 hypertensive patients aged between 12 and 40. The balance sheet they have drawn up is instructive. Despite investigation as intensive as could reasonably be performed in such a group in only 73 patients (32%) was a possible cause for hypertension found. In addition there were a further 40 patients not subjected to intravenous pyelography because their renal failure was too severe when first seen or because they died before the investigation could be done. Of the 73 patients in whom a secondary cause of hypertension was suspected only nine were thought suitable for surgical treatment. Nephrectomy was carried out on six patients for renal artery lesions or unilateral pyelonephritis, and in the other three patients the adrenal gland was explored or a renal capsulotomy done. In only three cases was the treatment successful in that no further drug treatment was needed.

Three cures in 229 patients—it is not an encouraging record. A curious feature of the series is that there were so few patients with disease of the main renal artery (only 12 material lesions were identified), and none of these patients

is recorded as having had reconstructive renal artery surgery. The low incidence of disease of the renal artery would be met with amazement bordering on disbelief by American surgeons at Houston and at the Cleveland Clinic, who see a highly selected population. However, even those patients referred to the hypertensive clinic of Hammersmith Hospital are themselves probably a selected group, and it may well be that in a completely unselected population of young hypertensives the true incidence of remediable secondary hypertension is still less than in the Hammersmith series.

Breckenridge and his colleagues point out the moral: that youth alone is an insufficient recommendation for extensive investigation, especially aortography, in the hypertensive patient. Since by far the commonest renal lesion in these young hypertensive patients was chronic pyelonephritis, which could usually be diagnosed by the intravenous pyelogram and by examination of the urine, it seems that aortography or divided function studies can be therapeutically justified only under special circumstances. Patients suitable for intensive investigation are those with a loud renal artery bruit to whom surgery can be offered and by whom it might be accepted, and possibly also those who prove unduly resistant to drug therapy, those who find drug side-effects intolerable, or those whose occupation or domicile makes adequate supervision of their therapy impossible.

Young hypertensive patients should certainly not be denied the benefits of intravenous pyelography, urinalysis, screening of blood electrolytes to detect primary hyperaldosteronism, and, if possible, screening of the urine to detect pheochromocytoma. These tests are simple, safe, and reasonably inexpensive in time and money. Except under special circumstances investigation should stop at this point, and the patient should be treated with hypotensive drugs unless the reasons for proceeding further are unusually compelling.

Intensive Care

The value of intensive care units in hospitals has become generally recognized in Britain only in the last five years. As the equipment used in the management of patients with severe cardio-respiratory illness has become more complex so has special training and experience become necessary for those looking after the patients. The best use of men and machines can be made if they are concentrated into one unit and patients who need specialized treatment or monitoring are admitted to it.¹

Few units in Britain have been working for more than a year or two, but there is now widespread interest in their establishment. In 1962 the Ministry of Health gave its blessing² to hospitals wishing to set up units; now the B.M.A. Planning Unit has issued a useful report³ by a working party under the chairmanship of E. J. Moran Campbell which gives advice on the form that units should take, based on the experience of 17 hospitals in the British Isles. This is the first publication from the Planning Unit, and Professor Henry Miller, its director, stresses that the report is in no sense a statement of B.M.A. policy but is an informed assessment of

current experience. The report defines the function of an intensive therapy unit (I.T.U.) as "the care of patients who are deemed recoverable but who need continuous supervision and need or are likely to need prompt use of specialized techniques by skilled personnel." When large hospitals have a divisional system the report suggests that specialties might have their own units, while in district general hospitals a communal I.T.U. might be better. The optimum size is said to be six to eight beds.

The report confirms earlier suggestions that the physician or anaesthetist in administrative charge of the unit should not have clinical responsibility for all patients, but it goes on to emphasize that the success of an I.T.U. depends on its staffing. "An I.T.U. succeeds if it has a dedicated staff who have the confidence and good will of the hospital—whatever formal arrangements are made." Two accounts published last month^{4,5} of the future organization of medical work in hospitals drew attention to the benefits of wider co-operation among hospital staff, and intensive therapy units will flourish only where this atmosphere exists. Perhaps most important, the report draws attention to the strain on patients and their relatives of the bustle of activity in these units, and the need for doctors to find time to explain what is going on. Technological medicine must not be allowed to become dehumanized.⁶

Outbreaks of Coxsackie B Infection

Nearly every year, generally in the summer months, outbreaks of infections caused by the enteroviruses make their appearance. Now that poliomyelitis can be controlled by immunization, the main pathogens are the E.C.H.O. and Coxsackie viruses. Fortunately these are more benign than poliovirus, but under certain circumstances severe and fatal disease can occur.¹ In the past few years laboratories throughout Britain have been sending in reports of micro-organisms isolated to the Central Public Health Laboratory at Colindale, and details of these are subsequently circulated weekly to many other laboratories and hospitals. This is a valuable and informative service.

Coxsackie viruses are isolated quite often in the summer and usually each year one or two strains are predominant. This year there were many isolations of Coxsackie B2 and B3 and of Coxsackie A strains from hand-foot-and-mouth disease.² In a report from the Public Health Laboratory Service published on page 575 of this week's *B.M.J.* it is clear that 1965 was a Coxsackie B5 year—the number of identifications made was greatly in excess of any year since 1960. A high proportion of the 1,160 reports came from London and the south-east, with very few isolations in the north of England, a few in Scotland, and none in Northern Ireland. The number of infections reported in 1965 started to increase in May and reached a peak in July and August. Infections were noted most frequently in children—41% of infections

occurred in children aged up to 9 years, and a further 19% in patients aged 10 to 19. Few were reported in patients over 50 years of age. The varied clinical features in the 900 cases ran true to form for Coxsackie B infections. Those observed most often were infections of the central nervous system (31%), with aseptic meningitis predominating. Next in order of frequency were cases of myalgia and Bornholm disease (23%), followed by respiratory disorders (15%), ranging from a cold, sore throat, croup, and pharyngitis to pneumonia. Gastrointestinal symptoms of diarrhoea, vomiting, and abdominal pain were encountered in 9%. Among the 48 patients (5%) with cardiac symptoms 41 had pericarditis, five had myocarditis, and in two a precise diagnosis was not made. In 13 patients a rash was the predominant symptom, usually rubelliform. Altogether there were six deaths, including two cases of myocarditis (one in an infant aged 11 days and one in an adult), and two infants died of "respiratory involvement." Respiratory and gastrointestinal symptoms were most common in children under 10, and next in order of frequency were disorders of the central nervous system. Over the age of 10 the systems most affected were the central nervous system and the muscles.

During the same epidemic a number of cases of Coxsackie B5 infection occurred in Essex, and in a recent study K. W. G. Heathfield and his colleagues³ report a detailed study on the neurological aspects of infection with Coxsackie B virus. Thirty-two patients were studied, and in 21 the central nervous system was clearly affected. Ten patients developed an aseptic meningitis with clinical features typical of this type of illness. Eleven patients were seen with a more extensive infection. These included three severe cases of acute meningoencephalitis in infants, all of whom recovered, though one remained retarded. In addition, there were four cases of acute meningoencephalitis in children, all of whom recovered, and two examples of a brain stem encephalitis in adults. Two fatal cases were observed: one, a patient of 28, died after four months in coma, and at necropsy the brain showed a severe necrotizing encephalitis, which affected in the main the medial parts of both temporal lobes. Coxsackie B5 had been isolated from the cerebrospinal fluid during life. The second death occurred suddenly in an adult; at necropsy an acute haemorrhagic leucoencephalitis was found. This account is of interest in the light of recent observations⁴ on the effect of herpes simplex virus on the central nervous system, for herpes virus can also produce a fulminating infection with sudden death and a subacute necrotizing lesion which seems to have a predilection for the temporal lobes. These reports remind us that though the non-polio enteroviruses are usually less virulent than poliovirus serious diseases can occur in which a brain-stem encephalitis and necrotizing encephalitis are among the more severe features

Natural History of Cerebral Angiomas

W. R. HENDERSON,* F.R.C.S.; R. DE R. L. GOMEZ,† M.D.

[WITH SPECIAL PLATE FACING PAGE 572]

Brit. med. J., 1967, 4, 571-574

This paper is based on 70 patients who were seen during 1946-61 and were followed-up in 1966. The main purpose is to assess the natural history of angiomas, with particular reference to haemorrhage; also to emphasize some aspects of management. Only six angiomas were removed.

The first comprehensive studies of angiomas were by Cushing and Bailey (1928) (Special Plate, Fig. 1) and by Dandy (1928), who described a few cases of epilepsy in which large angiomas were found during exploratory operation, usually for suspected tumour. The possibility of surgical removal, however, had to await the introduction of angiography by Egas Moniz in 1927; and later the widespread use of the percutaneous method in the investigation of subarachnoid haemorrhage revealed many smaller, previously silent, angiomas, and led to a pronounced increase in the numbers diagnosed during the past 20 years. Angiography enabled operations to be planned to ensure the essential early division of all feeding arteries, and it became possible to remove completely many small and medium-sized angiomas, and sometimes even the more challenging large angiomas (Norlen, 1949; Paterson and McKissock, 1956; Olivecrona and Ladenheim, 1957); fits, however, were not always abolished, and previous neurological disability often remained. Prevention of recurrent haemorrhage became the chief indication for operation, but the risk of haemorrhage had to be assessed against the possibility of operative damage.

More recently it became recognized that haemorrhage sometimes occurs from very small angiomas, designated "cryptic" hamartomas by Crawford and Russell (1956). They are often situated in the depth of a sulcus (Special Plate, Fig. 2) and are apt to produce a large intracerebral haematoma, sometimes without subarachnoid bleeding, that may be rapidly fatal (Margolis *et al.*, 1951; Kravenbühl and Siebenmann, 1965). It seems that minute angiomas are sometimes destroyed by the haemorrhage and consequently may not show on angiograms. They are an important cause of so-called spontaneous cerebral haematomas of unknown origin, especially in children and young adults, which, when diagnosed in time, are curable by urgent evacuation; haematomas caused most of the preventable deaths in this series.

Clinical Groups

Of the 70 angiomas 63 were found by angiography, 4 at necropsy, and 3 at operation. They varied in size from a few millimetres to 10 cm., and may be grouped into three sizes (Table I). The size of the angioma is important in relation to the incidence of epilepsy (Mackenzie, 1953); of cranial bruit, and of intracerebral haematoma, and to the possibility of surgical removal.

* Neurosurgeon, General Infirmary at Leeds.

† Neurosurgeon, Mexico City.

The first manifestations in 68 patients were: (1) haemorrhage in 53 patients (78%) from angiomas of all sizes but mainly smaller angiomas without cranial bruit; (2) epileptic fits in 11 patients (16%) with large angiomas and bruit; (3) progressive hemiparesis in two patients with basal angiomas; and (4) high intracranial pressure suggesting tumour in two patients.

TABLE I—Size of 70 Angiomas in Relation to First Symptoms

Size of Angioma	Haemorrhage	Epilepsy	Slow Hemiparesis	High Intracranial Pressure	No Symptoms
16 small (2 cm. or less)	16	—	—	—	—
35 medium (> 2—< 6 cm.)	30	2	—	1	2
19 large (6 to 10 cm.)	7	9	2	1	—
70	53	11	2	2	2

The ages at onset varied from 3 to 60 years; 21 patients were in the twenties and 16 were under 20. Silent angiomas were present in two patients with ruptured aneurysm.

Haemorrhage

Haemorrhage (subarachnoid, intracerebral, or intraventricular) occurred in 58 patients; in 53 it was the first manifestation, and five patients with large angiomas had late haemorrhage, many (10, 19, 23, 30, and 37) years after the onset of epilepsy or slow hemiparesis. After the first haemorrhage five patients died (three from intracerebral haematoma and two from late haemorrhage) and five angiomas were removed or clipped. There were 23 mild attacks of sudden headache without (or very brief) loss of consciousness or focal signs, and 21 moderate attacks with either loss of consciousness or focal signs, or both, that disappeared, so that 44 patients recovered completely; and there were nine severe attacks (four with known haematoma) followed by incomplete recovery.

A second haemorrhage occurred in 28 patients out of 48; five died from the haemorrhage (after intervals of five weeks, 15 months, two, seven, and nine years) and one angioma was removed. Further haemorrhages, making altogether three to six attacks, occurred in nine patients, one of whom died after the fourth haemorrhage; and another patient had nine almost certain haemorrhages (five proved by lumbar puncture), all followed by good recovery. Thus six patients (all with large or deep inoperable angiomas) died from recurrent haemorrhage. There were only seven short intervals, of less than six weeks, before 54 recurrent haemorrhages; 38 intervals were one year or longer, and 16 were 5 to 26 years. Only three of the nine patients who had severe first attacks had further haemorrhages. Seven patients had full recovery after all of three to nine

haemorrhages from medium-size inoperable angiomas (mostly supplied by choroidal arteries) and remained well 17 to 30 years after the first haemorrhage.

As regards permanent disability, 35 patients (60%) recovered completely from all attacks (Table II); and 12 had permanent residual signs, mainly hemiparesis or hemianopia, or occasionally cortical sensory loss or mild dysphasia, that were often slight and caused little or no disability. There was impairment of memory in one patient, and mild personality change in another. Eleven patients later developed occasional epileptic attacks. Two patients were not working.

TABLE II.—*Severity of Haemorrhage, Based on the Most Severe Attack, in 58 Patients*

Size of Angioma	Severity of Haemorrhage			Died	Total
	Mild	Moderate	Severe		
Small	5 (1)	7 (4)	3 (2)	2 (2)	17 (9)
Medium	10	9 (1)	7 (2)	4 (2)	30 (5)
Large	2	2	2	5	11
	17 (1)	18 (5)	12 (4)	11 (4)	58 (14)

The figures in parentheses are of known intracerebral haematomas.

It is well known that haemorrhages from angiomas are less fatal and cause less morbidity than haemorrhages from saccular aneurysms, that they occur at an earlier age, that recurrent attacks occur after longer intervals, often of many years, and that angiomas do not cause arterial spasm and cerebral infarction that sometimes produces severe permanent disability or fatality after rupture of an aneurysm. Haemorrhages from very small angiomas tend to occur in early life, as might be expected with a congenital lesion, but severe bleeding from large angiomas that contain so many abnormal vessels, surprisingly, often does not occur until later life, suggesting its dependence on degenerative changes; necropsies, however, often show evidence of previous clinically unrecognized slight leakages of blood (Russell and Rubinstein, 1963) that probably are more common than is known, especially from large angiomas. It seems from this small series that medium-sized surface angiomas often bleed into cerebrospinal fluid without causing permanent disability, and that their removal need not be attempted if the brain is likely to be damaged.

Intracerebral Haematoma

Haematomas were found at operation in 14 patients (Table II); four died. In five patients the cerebrospinal fluid was normal, which made early diagnosis more difficult, and in eight it contained blood; none had cranial bruit. Nine angiomas were small and five were of medium size (the largest was 5 cm.). There were no known haematomas with large angiomas that often extend from a wide base on the brain surface deeply to the ventricle and could bleed easily into cerebrospinal fluid, either directly or by tracking along the potential space between a dense angioma and brain. Blood may collect inside this space, forming a small haematoma that is discovered during removal of the angioma, or it may extend widely into the brain. A large haematoma occupies the white matter up to the cortex (Special Plate, Fig. 2), and the subependymal glia also seems to form a barrier; it is likely that fibre tracts at the site of bleeding are torn while nearby compressed tracts are capable of recovery, so that permanent focal signs are usually localized but may be severe—for example, monoparesis or quadrant hemianopia.

Clinically, there is great variation in the rapidity of onset. Usually sudden severe headache occurs with vomiting and perhaps neck stiffness, and, when the motor area is involved, rapid hemiparesis. Death may occur within a few hours, usually from ventricular haemorrhage (Crawford and Russell, 1956), and no effective treatment is possible. More commonly, and when operation is urgently necessary within a day or two, the sudden headache is followed after a delay of some hours

by progressive deterioration, with drowsiness deepening to coma, and with spreading signs and perhaps a dilating pupil which, when it occurs, is an important indication of haematoma; two such patients died in two and four days after late aspiration of 25 and 30 ml. of old blood (Special Plate, Fig. 2). With smaller haematomas improvement starts with return to consciousness within two days but focal signs often persist.

Large haematomas, up to 10 cm. long, are mostly in the central (sulcus) region, and there is early hemiparesis (nine haematomas arose from small convexity angiomas in the middle cerebral area), whereas haematomas nearer the poles of the hemisphere are usually smaller and have milder symptoms without focal signs. Diagnosis may be confused by a history of mild antecedent trauma to the head (as in two patients) that occasionally seems to precede haemorrhage (Margolis *et al.*, 1951; Crawford and Russell, 1956), and is probably coincidence, but if relevant it suggests that trauma may start bleeding from an angioma that is about to rupture spontaneously; negative burr-hole exploration for suspected extradural haemorrhage should include cerebral aspiration. In two patients with only drowsiness, inconspicuous signs, and normal lumbar puncture the symptoms appeared to have been gradual in onset, over a week or two, and were at first attributed to a rapidly growing cerebral tumour. Angioma should be suspected, first, when blood is obtained during burr-hole aspiration of a mass that produced symptoms of recent apparently gradual onset, because bleeding into a tumour is very rare; and, secondly, as a likely cause of cerebral stroke in children (six haematomas were in children aged 17 or younger). Permanent isolated focal signs—for example, hemianopia—in young patients after an uninvestigated acute cerebral illness, sometimes called meningitis, may have resulted from angioma haemorrhage.

Radiologically, there may be a laterally displaced pineal shadow. Angiography shows slight lateral displacement of the midline, which may be the only radiological evidence of haematoma, especially in the frontal or occipital region (a large angioma alone may produce a similar shift); but a haematoma in the central region, the common site, produces typical displacement of the middle cerebral artery, either downwards with parallel stretching of the ascending branches (Special Plate, Fig. 3) or upwards (Special Plate, Fig. 4).

Seven haematomas, sometimes unsuspected, were evacuated during craniotomy, and in seven patients up to 50 ml. of old blood was aspirated through a burr hole. Aspiration was sometimes late, or was inadequate, and probably all four deaths should have been prevented (two angiomas on the convexity were small and removable, and two were deep and inoperable). The patients who recovered remained well without recurrence

FIG. 3

of bleeding for 7 to 14 years. Burr-hole aspiration is sometimes satisfactory, but evacuation by craniotomy is usually better, especially when the angioma is removable; very small angiomas that are hidden in a sulcus may be traced by adherent clot inside the haematoma, as was proved histologically in one patient with a large haematoma but no angioma radiologically (Special Plate, Fig. 4). In very ill children with hemiplegia, dilated pupil, and possibly a history of recent mild head injury, it is probably safest to exclude a large central intracerebral (or extradural) haematoma by aspiration through two burr holes without angiography; an angioma can be removed after angiography later.

Epilepsy

Five of the 11 patients had no other complaint (except two with occasional migraine) during 10 to 40 years; four had late haemorrhage (two fatal) after fits for 10, 23, 30, and 37 years; and two patients died, one after epilepsy for 26 years (with, during the last nine years, gradual hemiparesis, dysphasia, and eventually mental deterioration), and the other (following rapid deterioration immediately after repeat angiography and subsequent radiotherapy) after mild epilepsy for about 10 years. The angiomas were superficial and large, 5 to 10 cm. in size (Special Plate, Fig. 6). Nine patients had cranial bruit. The classical combination of epilepsy and cranial bruit is strongly suggestive of angioma, but it may occur with a meningioma and is not diagnostic without subarachnoid haemorrhage. The fits, with or without loss of consciousness, were often Jacksonian; they were usually separated by intervals varying from months to several years, and were well controlled by anti-convulsant drugs. Removal of angioma was not attempted (occasionally the risk of producing increased disability may be justified when fits are frequent and disabling).

Eleven other patients had fits that started after, and presumably were caused by, haemorrhage, often within 12 months but occasionally after several years; usually, persisting signs of cerebral damage were present, and in five patients there had been a haematoma. In contrast to the epilepsy group, most of the angiomas were smaller, 4 cm. or less, and without a bruit. Posthaemorrhagic fits also were infrequent and were well controlled by drugs.

E.E.G. was of no value. In a few patients after epilepsy for many years it was normal; slow waves in two patients with gradual hemiparesis merely supported the obvious presence of a destructive cerebral lesion, but of course gave no indication of pathology.

Progressive Hemiparesis

Two patients with large angiomas in the basal ganglia had slowly progressive severe hemiparesis and sensory loss, without fits, for 20 and 19 years, when the latter patient died from haemorrhage; necropsy showed that the angioma was confined to and had destroyed the basal ganglia and internal capsule (Special Plate, Fig. 5). Slow hemiparesis was the initial symptom in five out of Paterson's (1955) nine cases of angioma in the basal ganglia.

N. L. BROWSE ET AL.: MANAGEMENT OF PULMONARY EMBOLI

FIG. 1.—Case 1. Ascending phlebogram of the clinically normal left leg showing typical recent thrombus. A loose thrombus of this size would probably be lethal if it broke free. The thrombus, easily removed, is shown below.

FIG. 2.—Case 2. Left, phlebogram showing a complete left iliac vein thrombosis with irregular fresh thrombus jutting into the vena cava. Right, phlebogram one year after plication of the inferior vena cava. The plication at the upper border of L3 is patent and the left iliac vein has fully recanalized.

FIG. 3.—Case 3. Percutaneous femoral puncture phlebogram of patient who had a pulmonary embolus six months after plication of the inferior vena cava without preoperative phlebography. The right inferior vena cava shows thrombosis and recanalization below the plication at the level of the body of L3, but there is a patent left inferior vena cava providing an unguarded route for emboli from the left leg.

High Intracranial Pressure

Two patients had high intracranial pressure with severe papilloedema and headaches of apparently gradual onset, without a history of fits or haemorrhage, that was suggestive of tumour. One very large space-occupying angioma was above the tentorium, and the other, of medium size, in the posterior fossa, obstructed the cerebrospinal fluid pathways.

Cranial Bruit

The presence or absence of a bruit, heard most easily over the eyeball, was recorded in 37 cases. It was nearly always present with large angiomas (the smallest was 4 cm.) but not with small ones (the largest without bruit was 5 cm.). Only one patient was aware of the noise.

Posterior Fossa Angiomas

Logue and Monckton (1954) described nine posterior fossa angiomas which usually produced cerebellar or lower cranial nerve signs; two in the cerebellum were removed and seven were in the brain stem. The clinical signs (without adequate history) may be wrongly attributed to tumour; similarly, intermittent symptoms from repeated small haemorrhages may be attributed to disseminated sclerosis. Our three patients with cerebellar angiomas remained well 7, 13, and 21 years after one or more mild haemorrhages; nevertheless their removal probably should have been attempted.

Angiography

Ideally, early management of subarachnoid haemorrhage rests on surgical observation from the day of haemorrhage, which is really the first investigation; the indication for and timing of angiography are based on the patient's (general and neurological) fitness primarily for possible operation and secondarily for angiography, which is potentially as risky as operation. Angiography should be regarded as a first-stage operation rather than as a diagnostic investigation.

Aneurysm is the commonest source of subarachnoid haemorrhage, and before angiography it is assumed that early operation may be required to prevent possible recurrent bleeding; on the other hand, a ruptured aneurysm often produces arterial spasm that may be dangerously increased by angiography during the first two or three weeks with resulting cerebral infarction (spasm sometimes spontaneously causes recurrent loss of consciousness and focal signs that are mistakenly attributed to recurrent haemorrhage). The third danger after haemorrhage is the formation of a large intracerebral haematoma (from angioma or aneurysm), which is very important because death from this cause can be prevented by prompt evacuation within a day or two; it is the most important complication of angioma haemorrhage. The suspicion of haematoma or of spasm, and therefore the timing of angiography, is based mainly on careful clinical observation for signs suggestive of progressive cerebral compression or transient increased spasm; the possibility of haematoma requires either immediate angiography or, when the patient is very ill, burr-hole exploration without angiography.

Angiography is not at any time without risk, and it is sometimes necessary to restrict it, or perhaps stop it after one injection, without completion of the series, which should never be routine. When an angioma is found on the first injected side, further injections are rarely required, either to demonstrate the complete blood supply of a large angioma, which is unnecessary except when the surgeon thinks it may be removable, or, unless there have been no focal manifestations, to exclude a coincidental ruptured aneurysm, which is rare. Such an aneurysm may be seen on the feeding artery to the angioma,

as in one of the two patients with silent middle cerebral angioma; the other patient had a ruptured posterior cerebral aneurysm that had produced partial oculomotor nerve paresis. Vertebral angiography was used conservatively because it seemed that the rare finding of a removable angioma or aneurysm in the posterior fossa (or occipital lobe) did not justify the added risk of routine complete four-vessel angiography.

The conventional three-exposure angiography seems to be adequate; rapid serial angiography is unnecessary even in the hope of showing with certainty a minute (not thrombosed) angioma, which, in any event, may be difficult to find at operation except in the wall of an obvious haematoma (Special Plate, Fig. 4). Repeat angiography after several years is also unnecessary and is inadvisable; in three patients the angioma showed no change in size after five to seven years. (In a 24-year-old patient with a 10-cm. angioma (Special Plate, Fig. 6) that had produced occasional mild focal fits for about 10 years, repeat angiography produced immediate severe hemiparesis and aphasia, followed by further rapid deterioration after radiotherapy, and death within a few months.) Post-operative angiography (a single lateral injection) was routine after excision or clipping of the angioma.

Operation

Removal of most deep (basal ganglia, choroidal, or brain-stem) angiomas is impossible, and there is no certainty that occlusion of a feeding artery that may give a branch to normal brain will not cause serious disability. Many superficial small and medium-size angiomas can safely be removed, but it is inadvisable to risk producing disability by attempting removal of large angiomas except perhaps when situated near a pole of the hemisphere.

There were 22 operations. Four angiomas up to 4 cm. in size were removed. The feeding arteries to six angiomas were clipped; two disappeared but four partially remained (without further bleeding during 9 to 13 years). In eight patients a haematoma was aspirated, usually through a burr hole. Three angiomas were found during exploratory operation, and one patient had flap decompression for high intracranial pressure but without improvement.

Radiotherapy was tried in five patients with large angiomas but produced no improvement, and four have died. McWhirter and Dott (1955) pointed out that the angioma blood vessels, though abnormal, are not neoplastic and that there is no reason to expect them to be more affected than the surrounding normal vessels. They stated that radiotherapy should not be employed, as have Paterson and McKissock (1956) and Olivecrona and Ladenheim (1957).

Follow-up

Twenty-one of the 69 patients followed up have died, 15 (22%) from the effects of the angioma and 6 from unrelated causes (four lived 7 to 11 years after subarachnoid haemorrhage and two with silent angiomas had ruptured aneurysm); one untraced patient was known to be alive eight years after haemorrhage. Most of the 15 patients died from haemorrhage: four from intracerebral haematoma, three from intraventricular haemorrhage, two from late haemorrhage (after 23 years' epilepsy and 19 years' hemiparesis), and one death followed vertebral angiography after full recovery from the third subarachnoid haemorrhage in eight years from a mid-brain angioma (previously shown by carotid angiography); all were proved at necropsy. Two sudden deaths without necropsy were assumed to have resulted from haemorrhage from large angiomas—one after epilepsy for 39 years and the other eight years after previous haemorrhage. The remaining three deaths (no necropsy) occurred in patients with very large supra-

tentorial angiomas after epilepsy for 10 and 26 years, and after a six-months' history of high intracranial pressure.

All 15 angiomas were thought to be either too large or too deep for removal except two small middle cerebral convexity angiomas with haematoma that should have been cured; and death after delayed evacuation of haematoma should not have occurred in two patients with deep angiomas. The five avoidable deaths were thus due to intracerebral haematoma or angiography. As regards intervals between first symptom and death, only 3 (4.4%) patients died, all from haematoma, within the first two months, and seven within 15 months; the remaining eight deaths occurred after 7 to 39 years. The earlier deaths were due mainly to haematomas from small angiomas, while the later deaths were in patients with large angiomas.

Conclusion

The natural history of angioma haemorrhage seems to be related to the size of the angioma. Haemorrhages from the common medium-size angiomas are usually mild and may recur at long intervals over many years. Small angiomas, on the other hand, are apt to bleed in children and rapidly produce a dangerous intracerebral haematoma in the first attack, whereas fatal haemorrhages from large (inoperable) angiomas often do not occur until later life, sometimes after fits or progressive cerebral disability for many years.

Forty-nine (84%) of the 58 patients who had haemorrhage were alive five years after the first bleeding; only two patients died from the effects of a safely removable angioma (with haematoma). These results probably justify a conservative surgical policy, but it is nevertheless believed that more angiomas should have been removed to prevent fatal haemorrhages that will no doubt occur in future years. Svien and McRae (1965) found that only 16% of 68 unoperated patients (out of a total of 95) seen at the Mayo clinic during 1920–61 had died from the angioma. We agree with their conclusion that, in retrospect, conservative treatment is appropriate for 80 to 85% of patients, but when patients are first seen the possibility of fatal recurrent haemorrhage is unpredictable, and some deaths will be prevented by excising the considerable number of angiomas that are removable without risk of producing serious neurological damage. It is, however, by the prompt evacuation of intracerebral haematoma that many avoidable deaths can be prevented.

It is emphasized that angiography should be used with restraint, especially in patients with large angiomas (and in the investigation of all subarachnoid haemorrhages), to avoid producing increased disability or fatality.

It is a pleasure to thank all the physicians who referred patients, and also the patients' general practitioners, for assisting with the follow-up.

Coxsackie B5 Virus Infections during 1965

A Report to the Director of the Public Health Laboratory Service from Various Laboratories in the United Kingdom*

Brit. med. J., 1967, 4, 575-577

Many laboratories throughout the United Kingdom send regular reports of the micro-organisms they identify to the Central Public Health Laboratory, Colindale, London N.W.9. During the early summer of 1965 it became apparent that infections with Coxsackie B5 virus were being reported much more frequently than in previous years. Contributing laboratories were therefore invited to complete a standard record containing more information than that usually included in the routine reports. These special records were analysed centrally and the findings are reported below.

Period and Duration of Outbreak

Table I shows the total number of Coxsackie B5 virus infections reported to Colindale routinely in 1965 and in each of the previous five years. It is evident that the 1,160 reports during 1965 were greatly in excess of those recorded in any previous year. The last year in which a substantial number of infections was reported was 1960; in the intervening years the number of B5 infections was small, though the number did increase in the year before the epidemic. In contrast to the B5 isolations, the total number of other Coxsackie B isolations during 1965 was less than in the previous few years.

TABLE I.—Coxsackie B5 and Other Coxsackie B Infections According to Year

Year	Coxsackie B5 Infections	Other Coxsackie B Infections
1960	467	168
1961	46	83
1962	10	286
1963	26	316
1964	104	462
1965	1,160	188

Of the total of 1,160 isolations routinely reported the special record cards mentioned above were received for 900—that is, 77% of the total. Table II shows the isolations according to the month in which the specimen was obtained from the patient and sent for examination. Of the 900 reports 232 did not contain the requisite date. Few of the remaining 668 isolations were obtained before May. However, in that month there were 30 isolations; in June there were 85; in July and August—the largest numbers of any month—199 and 183 respectively. After August the numbers declined to 68 in September and October; in December there were only 2.

* Standard Regions England and Wales as in 1965.

Table II also shows the number of reports received from each of the Registrar General's regions (Registrar General, 1965). At the outset isolations were reported from regions as far apart as London and the North-western Region. Taking the year as a whole the largest number of reports were received from the London and South-eastern, the South-western, the North-western, and the Eastern Regions of England and Wales.

Age

The age of the patients from whom the specimens were taken is shown in Table III. It is evident that infection was reported

TABLE III.—Infections According to Age and Sex

Age Group	Sex		Total Patients	
	M	F	No.	%
0-9 years	197	166	365†	41

† Including 2 sex not stated. ‡ Including 2 sex not stated.

most frequently in children—365 isolations (approximately 41% of the total) were obtained from children 9 years of age and under. (Of these 68 about 7% of the total were from children under 1 year.) Seven hundred and ninety-three specimens (about 88% of the total) came from patients less than

* The reports on which this survey is based were submitted from Public Health and other laboratories in the following areas: Bath, Bedford, Belfast, Birmingham, Bournemouth, Bradford, Brighton, Bristol, Cambridge, Carlisle, Chelmsford, Chester, Cirencester, Conway, Cottingham, Coventry, Dundee, Epsom, Exeter, Glasgow, Guildford, Hereford, Hull, Ipswich, Kingston, Leeds, Leicester, Liverpool, London, Luton, Maidstone, Manchester, Middlesbrough, Newcastle upon Tyne, Northampton, Norwich, Nottingham, Oxford, Plymouth, Portsmouth, Preston, Salisbury, Sheffield, Shrewsbury, Southampton, Southend, Stafford, Sunderland, Swansea, Taunton, Truro, Wakefield, Winchester, Worcester.

The survey was planned and initiated by Dr. A. J. H. Tomlinson, P.H.L.S. Laboratory, County Hall, London S.E.1. The results were analysed and the report prepared by Mr. John G. Pope and Dr. T. M. Pollock, Epidemiological Research Laboratory, Colindale, London N.W.9.

40 years old. In most age groups there was a tendency for more isolations to be made from males than from females.

Predominant Clinical Features

A variety of clinical features of various degrees of importance was often noted on the record of a single patient. Table IV, in which each patient appears only once, shows only the most important feature in each patient. This predominant clinical feature was selected from the other clinical features noted on the record according to an order of precedence depending on the system affected as follows.

Conditions relating to the central nervous system took precedence as the predominant clinical feature over any of the other diagnoses noted on the record. Conditions of the central nervous system were followed in descending order by conditions affecting the cardiac, muscular, respiratory, and gastrointestinal systems, the skin, and, finally, general symptoms—for example, pyrexia. Thus a patient with a cardiac lesion and also gastrointestinal features appears in the cardiac group only. Similarly, a patient with muscular symptoms and general symptoms appears in the muscular group only.

TABLE IV.—Predominant Clinical Features in 900 Patients

System Affected and Diagnoses	Total Patients	
	No.	%
Central nervous: meningitis, encephalitis	280	31.0
Cardiovascular: myocarditis, pericarditis, unspecified	48	5.3
Muscular: myalgia, chest pain, Bornholm disease	204	22.7
Respiratory: cold, sore throat, croup, pharyngitis, pneumonia, bronchitis, pleural pain, pleurisy, unspecified respiratory	134	15.0
Gastrointestinal: diarrhoea, vomiting, gastroenteritis, abdominal pain	77	8.6
Skin: rash	13	1.4
General: pyrexia, headache, etc.	34	3.8
Other: arthritis, hepatitis, glandular fever	5	0.6
No symptoms	41	4.6
No information	64	7.1

As shown in Table IV, a condition affecting the central nervous system was recorded in 280 individuals (31% of the total). Of these 228 were diagnosed as meningitis, 38 as possibly meningitis, and 14 as encephalitis. A cardiovascular condition was the most important feature on 48 occasions (5%). Forty-one of these cardiac conditions were diagnosed as pericarditis and five as myocarditis; in the remaining two cases the precise diagnosis was not specified. Muscular conditions were the most prominent feature in 204 patients (23%). This group included myalgia, patients diagnosed as suffering from Bornholm disease without a description of the symptoms, and chest pain without features suggesting pleural involvement. Respiratory conditions, including colds, sore throat, pharyngitis, croup, bronchitis, pneumonia, pleural pain, or pleurisy, predominated 134 times (15%). Gastrointestinal conditions, including diarrhoea, vomiting, and abdominal pain, were the most prominent feature 77 times (9%). Rash was the most prominent feature in 13 patients: in seven of these individuals the rash was described as rubelliform and in one as maculopapular; in the remaining five cases the character of the rash was not specified. General symptoms—pyrexia, headache, and malaise without specific localizing symptoms—occurred as the predominant feature in 34 patients. Five other conditions were also reported—three diagnosed as arthritis, one as hepatitis, and one as glandular fever.

There were six deaths, but these included one after a serious operation. One of the remaining five deaths occurred in an adult patient with meningitis. Myocarditis was diagnosed in two patients who died; one of these was an infant of 11 days and the other an adult. In two very young infants death resulted from respiratory involvement.

Forty-one individuals had no symptoms. In most of these symptomless excretors the reason why the specimen was sent

for examination was not given in the report: in the few cases in which the reason was recorded the individuals without symptoms were contacts.

Main System Affected at Different Ages

The predominant system affected at different ages is shown in Table V. It is clear that the central nervous system was more often involved than any other system in every age group except early infancy. In the age group 10–29 years this system was involved in 39% of the group. Cardiovascular conditions were more commonly reported in the older than in the younger age groups. As might be expected, muscular conditions, which included myalgia and Bornholm disease, were diagnosed in infants infrequently (4% of all diagnoses in the 0–11 months group), though there were numerous reports in older children and also in adults (18 to 29%). In infants the respiratory system was more often predominantly affected than in any other age group (32%); respiratory conditions were also common in children (21%), but were much less common in the older groups. Gastrointestinal illness was the predominant diagnosis in 21% of all cases in young infants and in 15% of the younger children, but these made up only a small proportion of the diagnosis in older persons.

TABLE V.—Main System Affected According to Age

System Affected	0–11 Months		1–9 Years		10–29 Years		30+ Years		Not Known		Total
	No.	%	No.	%	No.	%	No.	%	No.	%	
Central nervous	15	22.0	74	25.0	118	39.0	68	38.0	5	9.0	280
Cardiovascular	3	4.0	3	1.0	17	6.0	24	13.0	1	2.0	48
Muscular	3	4.0	53	18.0	88	29.0	46	26.0	15	28.0	205
Respiratory	22	32.0	62	21.0	27	9.0	15	8.0	7	13.0	133
Gastrointestinal	14	21.0	45	15.0	10	3.0	2	1.0	6	11.0	77
Rash	0	0.0	11	4.0	1	0.3	1	0.6	0	0.0	13
General	3	4.0	10	3.0	8	3.0	11	6.0	2	4.0	34
Other	0	0.0	1	0.3	3	1.0	1	0.6	0	0.0	5
No symptoms	0	0.0	29	10.0	1	0.3	1	0.6	10	19.0	41
No information	8	12.0	9	3.0	31	10.0	9	5.0	7	13.0	64
Total	68		297		304		178		53		900

In summary, therefore, over the age of 10 years the predominant features related to the central nervous system and muscular system. Under the age of 10 years the central nervous system and muscular system (except in infants) were also often mainly affected, but a common feature in infants and children was the predominant involvement of the respiratory system and gastrointestinal system.

Frequency of Symptoms

Though in some cases only the main symptom (see Table IV) was recorded, other reports did include one or more subsidiary clinical features. The total number of occasions in which each system was reported as affected is shown in Table VI. General symptoms were reported in 391 (43%) of the 900 cases, and it seems likely that such symptoms occurred more often but were not recorded. Next most frequent were reports of respiratory conditions—287 (32%) of the total cases. Conditions of the central nervous system and muscular conditions occurred in 31% and 30% respectively and gastrointestinal conditions in 20%. Cardiac conditions occurred in 6%.

TABLE VI.—Frequency of Reported Symptoms in 900 Patients

Category	Frequency	%
General symptoms*	391	43
Respiratory conditions	287	32
Central nervous system	280	31
Muscular conditions	271	30
Gastrointestinal conditions	180	20
Cardiac conditions	50	6
No information	64	7

Comment

The findings of the survey show clearly that reports of isolations of Coxsackie B5 virus from laboratories in the United Kingdom were much more common during 1965 than in any other recent year. The real prevalence of illness due to infection with the B5 virus cannot be known from a survey concerned only with cases in which the diagnosis was confirmed by laboratory examination, but reports were sufficiently numerous to suggest the occurrence of a substantial outbreak in 1965.

Even at the outset this outbreak does not seem to have been confined to any one locality; apparently dissemination was rapid and widespread. In May, for example—the month in which an excess of Coxsackie virus isolations was first noted—reports were received from five widely separated regions and from all areas during the subsequent months. The reports, however, do not give a reliable indication of the relative prevalence of the morbidity in different regions. It is true that reports from laboratories in different locations varied substantially in number, but the differences were probably affected by factors which cannot be assessed in the circumstances of the investigation—for example, the relative frequency with which family doctors in each area requested virological examination for their patients.

The analysis indicates that the outbreak began in the early summer, reached its greatest intensity during the later summer months, and declined in the winter. This is in keeping with the general experience of infections with Coxsackie viruses. Vernon (1964) noted that laboratory reports were most frequent during late summer and autumn in the United Kingdom.

In considering the age groups affected it should be appreciated that the relative prevalence of illness as shown by laboratory reports is bound to be influenced by the proportion of sick persons in each age group for whom a virological examination was requested. For example, there might be a tendency for virological examination to be requested in a larger proportion of sick children as compared with adults. If this were so it would, of course, tend to increase the relative proportion of laboratory reports of infections in children. However this may be in the circumstances of the survey, there is no doubt that a striking preponderance of laboratory reports in 1965 related to young children. Moreover, it might be expected that this age group would be relatively susceptible, since, owing to the minor prevalence of the B5 virus in earlier years, young children must have had less opportunity than adults to acquire immunity by natural infection.

A first-hand and detailed account of clinical symptoms is not possible from this type of laboratory survey, but clinical descriptions of cases of Coxsackie B5 infection during 1965 have been given by Heathfield *et al.* (1967) and Brodribb (1966). The laboratory reports, however, do emphasize the wide variety

of symptoms with which Coxsackie B5 infection may be associated. A similar diversity of symptoms has been reported from other countries; Siegel *et al.* (1963), for example, in an outbreak in Virginia observed chest pain, abdominal pain, pleural effusion, pericarditis, fever, myalgia and headache, painful hepatic or splenic enlargement with fever, nausea and vomiting, usually with pharyngitis and conjunctivitis, and pneumonitis. Other reports of the varied symptoms associated with Coxsackie B5 infection have been published by Gordon *et al.* (1959). In assessing the relative frequency of specific symptoms it must be remembered that virological examination may have been requested more often from patients with certain clinical features. Laboratory reports therefore do not necessarily indicate the real prevalence of specific symptoms in the outbreak. Nevertheless, a striking feature of the reports is the large proportion—almost one-third of the total—in which symptoms indicative of meningitis were the principal feature of the illness. Rubin *et al.* (1958), who first recorded an outbreak of meningitis due to Coxsackie B5 virus, observed that children were principally affected. This may not be a constant feature of morbidity due to Coxsackie B5 involvement since in the cases reported from the laboratories the central nervous system was affected very often in young adults as well as in children.

The few cases without symptoms re-emphasize that, as reported by Spicer (1961), excretion of Coxsackie B5 virus need not necessarily be associated with illness.

Summary

Laboratory reports of Coxsackie B5 virus were much more numerous in the United Kingdom during 1965 than in any previous year, and a widespread outbreak seems to have occurred during the summer months. These reports were concerned with a selected group of patients from whom virus was recovered. Among these patients respiratory symptoms, meningitis, myalgia, and gastrointestinal symptoms were common. Children were especially susceptible.

Normal Absorption in Thai Subjects with Non-specific Jejunal Abnormalities*

FRANK J. TRONCALE,† M.D.; GERALD T. KEUSCH,‡ M.D.; LOUIS H. MILLER,§ M.D.
RAY A. OLSSON,|| M.D.; RICHARD D. BUCHANAN,§ M.D.

Brit. med. J., 1967, 4, 578-580

There is a growing belief that subclinical tropical sprue is widespread in tropical countries (Klipstein, 1967). This opinion is based on studies of asymptomatic adults in India (Baker *et al.*, 1962), Pakistan (Russell *et al.*, 1966; Lindenbaum *et al.*, 1966b), and Thailand (Sprinz *et al.*, 1962), in whom jejunal histological abnormalities and impaired xylose absorption were frequently found. Recent studies in Haiti by Klipstein *et al.* (1966) show that this condition is very common in individuals complaining of one or more symptoms of the disease. The ease with which the same histological and biochemical abnormalities could be demonstrated in asymptomatic subjects led these workers to speculate that tropical sprue is a disease with a wide range of expression and that the overt cases represent only a fraction of the total number affected.

Because a jejunal lesion has been found commonly in asymptomatic subjects in Thailand (Sprinz *et al.*, 1962), we undertook to study its functional expression with a wider variety of tests than previously employed in order to assess the lesion as a possible precursor of tropical sprue.

Methods

Forty volunteer subjects, primarily from two villages on the outskirts of Bangkok, gave informed consent and were admitted to hospital for the studies to be described. There were 22 females aged 16-72 years and 18 males aged 13-45 years. History and physical examination were within normal limits. The following were performed in every subject: complete blood counts, total serum protein, protein electrophoresis, serum phosphorus, calcium, iron, and beta-carotene. Urinalysis and determination of blood urea nitrogen and serum creatinine were also carried out in all subjects and found to be normal by North American standards. Chest x-ray examinations, performed in all subjects, were also normal.

Five-hour urinary D-xylose excretion and two-hour serum xylose levels were measured in fasting subjects. All subjects received 25 g. of xylose, except for three who received 0.5 g./kg. (13.7, 22.0, and 22.6 g.). Urine and serum specimens were kept frozen after collection. The xylose determination (Roe and Rice, 1948) was performed within 24 to 48 hours after completion of the test.

Vitamin-B₁₂ absorption was measured by the Schilling (1953) technique, ⁵⁷Co vitamin B₁₂ (Racobalamin) with intrinsic factor being used. Vitamin-A absorption was tested in fasting subjects by the oral administration of a dose of 260,000 international units mixed in corn oil. Serum levels were measured before and five hours after ingestion of vitamin A (I.C.N.N.D., 1964).

For the lactose-tolerance test an oral dose of lactose (1.5 g./kg. body weight) was administered. The glucose-tolerance test was performed with an oral dose of 0.75 g. of glucose/kg. body weight, an amount equimolar to the glucose content of the lactose in the lactose-tolerance test. Blood glucose was estimated (Technicon AutoAnalyzer method, 1937) before and 15, 30, 45, 60, 90, and 120 minutes after each sugar was administered.

Stools were collected for three to six days and were analysed for fat by the method of van de Kamer *et al.* (1949). Because fat intake in the average Thai diet is low (I.C.N.N.D., 1962), a daily supplement of 75 g. of butter was given during the collection period. Carmine red dye was given orally to mark the beginning and end of the collection periods.

Fluoroscope examination of the upper gastrointestinal tract, with small-bowel follow-through studies, was also made. (We are indebted to Major Chitti Palavatana for carrying out the x-ray studies.)

Small-bowel biopsy specimens were taken from the jejunum with a Crosby biopsy capsule (Crosby and Kugler, 1957) after x-ray verification of the position of the capsule. The specimens were orientated with the mucosal side up on filter paper and were fixed in 10% buffered formalin. Haematoxylin and eosin, periodic acid-Schiff, and iron stains were done on all material. In order to minimize artifacts resulting from tangential cutting, care was taken to ensure that the plane of sectioning was parallel to the long axis of the villi and perpendicular to the luminal surface (Rubin and Dobbins, 1965). Measurements of overall mucosal thickness and villus/crypt ratio were made in eight patients by methods similar to those of Swanson and Thomassen (1965).

Results

Laboratory data are shown in the Table. Urinary excretion of D-xylose after a 25-g. dose was 5.84 ± 1.54 (S.D.) g. in 36 subjects. The mean two-hour serum level was 39.8 ± 7.5 (S.D.) mg./100 ml. The percentage of xylose excreted by the three subjects given the smaller dose (0.5 g./kg. body weight) was comparable to that after a 25-g. dose. Mild diarrhoea consisting of two to four watery stools occurred after ingestion of the 25-g. dose in three subjects. Five-hour urine volumes were above 225 ml. in all subjects tested.

Little or no increase in blood glucose occurred after oral lactose administration in the 39 subjects tested (Fig. 1), the mean maximum rise being 2.97 ± 3.07 mg./100 ml. Diarrhoea, consisting of up to 10 loose stools, or abdominal cramps, or both, occurred in 28 of the 39 subjects.

In contrast with the flat lactose-tolerance test, glucose absorption was usually normal. The mean maximum rise in blood sugar after ingestion of 0.75 g./kg. body weight of glucose was 42.5 ± 20.5 (S.D.) mg./100 ml. in 33 subjects (Fig. 1). Only four subjects showed a rise of less than 20 mg./100 ml. (7, 15, 16, and 19 mg./100 ml.). In four other subjects given 100 g. of glucose the mean maximum rise in blood sugar was 61.5 mg./100 ml.

Vitamin-B₁₂ absorption was normal in 33 out of 34 subjects tested (Fig. 2). One subject with a haemoglobin of 12.4 g. excreted 4% of the dose.

Stool fat excretion averaged 2.31 ± 1.37 g./day in 35 subjects tested. The values were below 5 g. in all except two, in whom the fat excretion was 6.3 and 6.8 g./day (Fig. 2).

Vitamin-A tolerance in 24 out of 27 subjects showed a rise of more than 125 μ g./100 ml. above the control value (Gardner and Perez-Santiago, 1956).

The mean serum total cholesterol was 177.5 ± 31 mg./100 ml. in 25 subjects tested. There was no correlation between xylose excretion and serum cholesterol (Robins et al., 1967).

The following mean levels ($\pm$ S.D.) were obtained (the number of subjects tested is in parentheses): serum calcium, 9.31 ± 0.49 mg./100 ml. (29); serum beta-carotene, 133.1 ± 65.0 μ g./100

ml. (34); serum albumin, 4.18 ± 0.56 g./100 ml. (32); haemoglobin, males 13.8 ± 1.9 g./100 ml. (18), females 12.1 ± 1.2 g./100 ml. (22).

Fifteen subjects were found to harbour the following small-intestinal parasites: *Ascaris* alone in 11, *Ascaris* and hookworm in one, hookworm alone in one, hookworm and *Strongyloides* in one, and *Giardia lamblia* in one. No difference in absorption tests was noted between these subjects and the 24 whose stools were negative for parasites, with one exception. Subject 8, whose stools contained *G. lamblia*, excreted the lowest xylose recorded—2.99 g.

FIG. 2.—Individual values for cobalt-57 vitamin B₁₂ urinary excretion (Schilling test) and for stool fat excretion in Thai subjects. Horizontal lines indicate lower and upper limits of normal, respectively, by Western standards.

The small-bowel pattern by x-ray examination was normal in the 29 subjects studied, except for mild mucosal irregularity in the ileum of one. In six subjects wormlike objects, probably ascarids, were seen in the mid-ileum.

A jejunal biopsy was obtained in each of the 40 subjects. The specimens were reasonably uniform in appearance, with the same mild histological abnormalities as noted in a previous report from Thailand (Sprinz et al., 1962). Under the dissecting-microscope the villi were irregular in height and thickness

FIG. 1.—Comparison of mean maximal rise in blood glucose over fasting value in Thai subjects after lactose- and glucose-tolerance tests ± 1 S.D.

FIG. 3.—Biopsy showing villus shortening, decreased villus/crypt ratio, and increased cellularity of the lamina propria. (Haematoxylin and eosin. $\times 125$.)

and usually leaflike or tongue-like in overall shape. In no specimen did fingerlike forms predominate. A flat or convoluted mucosal pattern was not seen in any patient. Under the light microscope the most impressive changes were villus-shortening with a decrease in the villus/crypt ratio, and uniform infiltration of the lamina propria with plasma cells and lymphocytes (Fig. 3). In the eight biopsies measured the average total villus/crypt thickness was $520\ \mu$ (range 420 – $630\ \mu$) and the average villus/crypt ratio was $2.3:1$ (range $1.9:1$ – $3.1:1$). Periodic-acid-Schiff and iron stains were unremarkable. No correlation was noted between the degree of microscopic or gross abnormality of the biopsies and any of the laboratory findings.

Discussion

In this population of asymptomatic Thai subjects the results of fat, vitamin-B₁₂, vitamin-A, and glucose-absorption tests were comparable to the results obtained in North American subjects (Sheehy and Floch, 1964). Xylose and lactose absorption and the histological appearance of the jejunal mucosa were different, however. Changes of similar degree have been found by others in apparently healthy subjects and interpreted as indications of subclinical intestinal disease (Baker *et al.*, 1962; Russell *et al.*, 1966; Lindenbaum *et al.*, 1966b). Is there any evidence to support this contention?

Urinary xylose excretion after a 25-g. dose in this population (5.84 ± 1.54 g.) is essentially the same as Gardner and Perez-Santiago (1956) (5.60 ± 0.60 g.) and Butterworth *et al.* (1959) (5.70 ± 1.40 g.) have reported from Puerto Rico, and Lindenbaum *et al.* (1966b) from East Pakistan (5.38 ± 1.57 g.). The Thai results are significantly lower than those of a group of North Americans studied in our laboratory (Keusch *et al.*, unpublished data). A similar difference was found by Lindenbaum *et al.* (1966b) between "protected" Westerners living in Pakistan and Pakistanis. While the reasons for this mild reduction in xylose excretion are not apparent, it is important to point out that these results are clearly higher than values found in classical tropical sprue (Sheehy and Floch, 1964).

The xylose excretion in the present study and in Pakistanis (Lindenbaum *et al.*, 1966a) has a bell-shaped distribution. Therefore it is not valid to use a criterion of normality—for example, greater than 5 g. excretion—derived from a different group (North Americans), as is customary in many clinics. Arbitrarily applying such a criterion would divide these homogeneous populations studied in the tropics.

Though lactose malabsorption has been observed in tropical sprue (Bayless *et al.*, 1964), it has also been described in a variety of other gastrointestinal diseases (Haemmerli *et al.*, 1965), as a possible genetically controlled enzyme defect (Cook and Kajubi, 1966), and in a surprisingly high percentage of normal adults (Friedland, 1965). The cause in the Thai is not clear. However, in view of what is apparently a universal occurrence of lactose malabsorption in Thais, the test is of no value in this population as a screening test for tropical sprue (Sheehy and Anderson, 1965).

Interpretation of the very mild non-specific jejunal abnormality is also difficult. Similar histological changes have been reported in kwashiorkor (Burman, 1965), hookworm disease (Tandon *et al.*, 1966), viral illnesses (Sheehy *et al.*, 1964), rosacea (Watson *et al.*, 1965), acute diarrhoea (Lindenbaum, 1965), and after triparanol administration (McPherson and Summerskill, 1963). None of these conditions was present in our subjects. What, then, is the relation between this non-specific histological abnormality and tropical sprue? It has been suggested that there is a spectrum of small-bowel disease in the tropics which ranges from mild and asymptomatic malabsorption to overt sprue (Klipstein *et al.*, 1966). Furthermore, this coexistence of tropical sprue and milder forms of

jejunal abnormality in the same tropical population has been cited as evidence for an association between the two processes (Klipstein, 1967). However, our results fail to support this contention, since intestinal function in Thai subjects with non-specific jejunal abnormalities is different from that in overt tropical sprue. Furthermore, Pakistanis with similar histological changes failed to show improvement in absorption tests after treatment with tetracycline or folic acid, which are usually effective in tropical sprue (Lindenbaum *et al.*, 1966a).

Summary

Forty asymptomatic Thai subjects were studied for evidence of tropical sprue by means of the following tests: xylose excretion, ⁵⁷Co vitamin-B₁₂ and vitamin-A absorption, faecal fat excretion, lactose and glucose tolerance, small-intestine radiographs, and jejunal biopsy. Xylose excretion was lower than in North American subjects but above the range expected in tropical sprue. Lactose malabsorption and mild non-specific histological abnormalities of the jejunal mucosa were present in all. The other studies showed nothing abnormal. These findings were considered insufficient to support a diagnosis of subclinical tropical sprue, and thus we have no evidence for sprue as a widespread disease in Thailand.

We are indebted to Colonel Edward H. Johnston for helpful criticism of the manuscript; to Captain S. W. Nye for helpful discussion in the early stages of the work; to Mrs. Yupa Kasemsant for her help in providing the subjects used in the study; to Miss Natamnuay Soparpun for providing nursing supervision of the study subjects; and to the Laboratory Service of the Clinical Research Center, S.E.A.T.O. Medical Research Laboratory, for performing the chemical analyses.

Requests for reprints should be addressed to Lieutenant-Colonel Ray A. Olsson.

Prognosis and Treatment of Idiopathic Facial (Bell's) Palsy

D. TAVERNER, M.D., F.R.C.P.; F. KEMBLE,* M.D., M.R.C.P.; S. B. COHEN, M.B., CH.B.

Brit. med. J., 1967, 4, 581-582

Previous reports from this department based on controlled clinical trials (Peiris and Miles, 1965; Taverner *et al.*, 1966) have described methods for the early establishment of an accurate prognosis in idiopathic facial palsy and for the reduction in the incidence of denervation, with permanent sequelae, in this common condition. The present communication describes our experience of the use of these two methods in the routine management of facial palsy in the two years following the controlled trials. The results support the claims previously made, and we are now confident that these methods should be introduced into routine medical practice.

Material and Methods

All patients attending the department of electromyography in the 23 months following the conclusion of the previous study (Taverner *et al.*, 1966) who were suffering from their first attack of idiopathic facial paralysis of not more than five days' duration are included. It was laid down that patients known to be in early pregnancy or to be suffering from diabetes mellitus, severe hypertension, or active peptic ulceration were to be excluded. Four patients were affected. The criteria for diagnosis were the same as those previously used (Taverner, 1955). The patients were allocated to treatment or observation groups on the basis of the threshold to anodal galvanic stimulation of the tongue by the method of electrogustometry (Krarup, 1958; Peiris and Miles, 1965). Treated patients were given five daily intramuscular injections of 80 units of adrenocorticotrophic hormone (A.C.T.H. gel), then 60, 40, 20, and 10 units on successive days. In 26% of the cases the injections were given in the outpatient department of the General Infirmary at Leeds. The remainder were given by the patients' general practitioners or by the district nurse. Some patients were examined electromyographically as described by Langworth and Taverner (1963).

At least three months after the onset of paralysis the final evaluation was made on clinical grounds, and patients with evidence of denervation were followed until no further improvement could be detected. In all except a few very mild cases each patient was seen by more than one observer. Two patients failed to reattend and have been excluded. Three others defaulted from the final assessment, but a reasonable conclusion seemed possible by combining the last clinic record with a report from the family doctor.

Clinical assessment of function in the facial muscles was estimated in terms of a percentage of the normal function of the orbicularis oris, orbicularis oculi, and frontalis muscles on the unaffected side. The results were classified as complete recovery or denervation. Denervation was recorded in the presence of any permanent defect of voluntary movement or any degree of associated movement, however slight.

Results

A study was made of 383 consecutive patients with idiopathic facial palsy of not more than five days' duration. Two de-

faulted—one treated and one observed—leaving 381 for analysis (Table I). There were 191 females, mean aged 42.4 years, and 190 males, mean age 40.1 years.

TABLE I.—Age and Sex Distribution of 381 Consecutive Patients With Idiopathic Facial Palsy

Category	Males		Females		Total
	No.	Age	No.	Age	
Treated	116	42.1 (10-77)	100	42.8 (10-77)	216
Untreated	74	37.0 (4-73)	91	41.8 (2-83)	165
Whole group ..	190	40.1	191	42.4	381

Prognosis.—Satisfactory normal responses to the anodal galvanic threshold test were obtained in 165 patients. The threshold was less than 10 μ A, and there was less than 5 μ A difference between the two sides. The remaining patients were unable to co-operate, were heavy smokers with high thresholds, or had large differences in threshold between the two sides. They were treated with A.C.T.H. gel because of the risk of denervation. The sex and age distribution in the two groups was essentially the same (Table I). Of the 165 untreated patients 153 (93%) recovered completely, as predicted, and 12 underwent denervation, only two seriously (Table II). The 10 with more than 70% recovery of function were fully satisfied with the outcome and considered themselves cured. Six of these 10 patients recovered more than 90% of normal power, and previous denervation was revealed by trivial flickers of associated movement. Retrospective analysis of the clinical records of the two patients with moderate to severe denervation showed that both had admitted subjective disturbance of taste when first seen. The more severely affected had also described hyperacusis and had later developed a significant difference in anodal galvanic threshold between the two sides.

TABLE II.—Outcome in the 12 Patients Who Developed Denervation Among the 165 Untreated Patients

Degree of recovery	..	..	..	<30%	30-70%	>70%
No. of patients ..	..	..	..	1 (8%)	1 (8%)	10* (84%)

* Six of these patients recovered more than 90% of their normal function.

Treatment.—Of 216 patients treated with intramuscular injections of A.C.T.H. gel 178 (82.5%) recovered completely and 38 developed denervation. Only 11 of the latter were affected to a moderate or severe degree (Table III); 27 were only slightly affected and considered themselves cured, and 14 of them recovered over 90% of normal function.

TABLE III.—Outcome in the 38 Out of 216 Patients Treated with A.C.T.H. Who Developed Denervation

Degree of recovery	..	..	..	<30%	30-70%	>70%
No. of patients ..	..	..	..	6 (15%)	5 (13%)	27* (72%)

* Fourteen of these patients recovered more than 90% of their normal function.

Overall Outcome.—The results can best be illustrated by contrasting them with the null hypothesis that neither the prognostic testing nor the treatment had any influence whatever on the outcome. In a series of controlled therapeutic trials over many years we have repeatedly found that the proportion of unselected patients with idiopathic facial palsy developing denervation, using the very strict criteria here applied, is very

Departments of Electromyography and Medicine, The General Infirmary at Leeds 1.

* Present address: Department of Neurology, Queen Elizabeth Hospital, Birmingham 15.

close to 40% (Taverner, 1954; Mosforth and Taverner, 1958; Langworth and Taverner, 1963; Fearnley *et al.*, 1964; Taverner *et al.*, 1966). Taverner (1959) studied 164 successive patients with denervation and found less than 30% recovery in 38%, 30–70% recovery in 23%, and over 70% recovery in 39%.

In the present inquiry 381 patients were studied. In all, 50 (13%) of them developed denervation in contrast to the 150 (40%) that might have been expected. In addition, the degree of denervation was much less severe than could have been expected—a “shift to the right” (Table IV). The proportion of patients with severe denervation—that is, less than 30% of return of function—has fallen from 15% to 1.8%.

TABLE IV.—Observed Outcome in 381 Consecutive Patients with Idiopathic Facial Palsy Compared with the Expected Result (See Text)

Degree of Recovery:				< 30%	30–70%	> 70%
Expected	..	..	..	57 (15%)	34 (9%)	61 (16%)
Observed	..	..	..	7 (1.8%)	6 (1.6%)	37 (10%)

Side-effects.—Two patients complained of dyspepsia suggestive of peptic ulceration, and one of them probably bled fairly severely. Both recovered spontaneously and no permanent ill effects were observed.

Discussion

The method of anodal galvanic testing provides a means of selecting those patients with idiopathic facial palsy who are going to recover completely, with an accuracy of nearly 95%. Its reliability can be increased by noting those patients with a normal threshold who admit to subjective disturbance of taste or to hyperacusis. Daily testing of the threshold will increase its accuracy still further. The importance of the test lies in the fact that it justifies the omission of A.C.T.H. gel therapy from a group of patients who do not need it. The converse proposition, that patients with an abnormal galvanic threshold will develop denervation, is not strictly true. In a few patients seen after five days of paralysis, differences of up to 25 μ A in the threshold on the two sides have been followed by complete recovery. If the threshold is “off scale”—that is, over 300 μ A on the affected side—denervation is invariable in untreated cases. However, our information on this point is scanty because in such patients the clinical picture has usually been modified.

Anodal galvanic stimulation tests the integrity of the chorda tympani nerve (Taverner, 1965), which leaves the facial nerve at a variable point along its descending course through the mastoid air cells (Anson *et al.*, 1963). The section of nerve running from the geniculate ganglion to a point between the branch to the stapedius muscle and the chorda tympani has a special microscopic structure (Sunderland and Cossar, 1953). This section of the facial nerve forms a single bundle with a dense, thick, perineurial sheath surrounded by a thicker but less dense epineurium merging with the walls of the bony canal. The rest of the nerve consists of a plexus of tiny nerve bundles with many anastomoses. Each small bundle has a thin perineurium and the whole is surrounded by a loose perineurium. It seems from our results that complete recovery is likely when the lesion causing the paralysis is situated distally. In this section of the nerve any swelling of the nerve bundles is con-

tained by the perineurium rather than by the bony walls of the Fallopian canal. It is probable that the mid-portion of the nerve, with its dense perineurium surrounding a single, compact bundle of fibres, may be especially liable to internal damage secondary to swelling. This would explain the high liability to denervation when the chorda tympani is involved (Peiris and Miles, 1965).

The results of A.C.T.H. therapy can be regarded as satisfactory in that the overall incidence of denervation has been reduced by two-thirds and of severe denervation with permanent disfigurement by 90%. There is no evidence that the severity of Bell's palsy has changed spontaneously in recent years. It has been shown that the prognosis is better in younger patients, but the age distribution of the various groups of patients in the present series is exactly the same as in the past. Further improvement is to be expected if treatment is begun on the first day of palsy. This would be justifiable in all cases of severe facial palsy if facilities for anodal galvanic testing are not immediately available.

It is still not clear why A.C.T.H. should succeed when oral corticosteroids fail (Taverner, 1954), but this effect has been noted before in neurological conditions (Miller *et al.*, 1961). A rigorously controlled trial to test this point has now been instituted in this department.

Summary

The results obtained in the management of 381 consecutive patients with idiopathic infranuclear facial (Bell's) palsy are reported.

Measurement of the threshold for anodal galvanic stimulation established the prognosis for recoverable conduction block with an accuracy of over 90%.

Treatment with A.C.T.H. gel intramuscularly was given to 216 patients. The results in the whole group of 381 patients show a reduction in the overall incidence of denervation by two-thirds and of severe denervation by 90%.

We thank Miss L. Lodge and Mr. M. Twitchett for their expert technical assistance. We are indebted to the many doctors who have referred patients so promptly. We are grateful to the chairmen and secretaries of the local health committees in Leeds, Bradford, Barnsley, Dewsbury, and the West Riding for their enthusiastic co-operation.

Gamma-M Deficiency Predisposing to Meningococcal Septicaemia

Brit. med. J., 1967, **4**, 583-586

Before his death from cerebrospinal fever Dr. G. D. Heist showed that he was one of the rare individuals whose blood had no bactericidal action on meningococci (Heist *et al.*, 1922). His father and four uncles also died of illnesses resembling meningococcal infections. We have observed two patients with fulminating meningococcal septicaemia who had abnormally low serum γ M globulins. Noting the susceptibility of Dr. Heist and possibly his family to meningococcal infections, and the possibility of a causal relation between a deficiency of serum γ M globulin and meningococcal infection, we carried out a survey of the immunoglobulin levels in the relatives of our two patients and made a study of antibodies to meningococci.

Subjects

Propositi

The immunoglobulin levels of five children suffering from meningococcal meningitis or septicaemia were studied. Brief summaries of their case histories are shown below.

Case 1.—An 8-year-old West Indian boy was admitted in a state of shock with an ecchymotic rash which had started 12 hours earlier. Waterhouse-Friderichsen syndrome was diagnosed, and treatment with intravenous antibiotics, hydrocortisone, and plasma expanders started immediately, but he became comatose and died four hours later. Before treatment started the plasma cortisol level was 61 μ g./100 ml. and the neutrophil count 9,000/cu. mm., with a marked left shift. Meningococci were isolated from blood cultures. Necropsy revealed bilateral haemorrhagic necrosis of the adrenals, fibrin occlusion of subcutaneous and dermal vessels with haemorrhage into the dermis, pulmonary congestion, and oedema.

Case 2.—A 5-year-old boy was admitted because of generalized convulsions, neck stiffness, and a fever of 107.4° F. (41.9° C.) which had begun eight hours earlier. Cerebrospinal fluid was normal and antipyretics were effective initially, but eight hours later hyperpyrexia returned accompanied by coma and a purpuric rash. A diagnosis of meningococcaemia was made and was later confirmed by blood culture. The neutrophil count was 5,000/cu. mm. and showed an extreme left shift. Despite treatment he died two hours later. The plasma cortisol level just before treatment with corticosteroids was 208 μ g./100 ml. Necropsy revealed no important abnormality apart from purpura.

Case 3.—This patient was a first cousin of Case 2. When 4 weeks old and asymptomatic she was found to have normal immunoglobulin levels for her age during screening of the relatives of Case 2. At the age of 9 weeks she was admitted because of neck stiffness and fever. The neutrophil count was 7,000/cu. mm., with a marked left shift. Blood and C.S.F. cultures grew meningococci. She responded to antibiotic therapy and made a complete recovery.

Case 4.—An 11-month-old girl was admitted because of a two-day history of fever and neck stiffness. Her blood showed a neutrophilia with a left shift. Meningococci were grown from both blood and C.S.F. cultures. Chemotherapy resulted in a slow but complete and uneventful recovery.

Case 5.—An 8-week-old baby was admitted because of fever which had not responded to penicillin. Examination showed a

petechial rash and a bulging anterior fontanelle. The C.S.F. contained moderate numbers of neutrophils, some of which contained Gram-negative diplococci, glucose 35 mg./100 ml., and protein 335 mg./100 ml., but yielded no bacterial growth. A clinical diagnosis of meningococcal meningitis was made, and with intensive chemotherapy she recovered completely.

Families

A survey of the immunoglobulin levels of all the available relatives of Cases 1 and 2 was carried out shortly after the death of these patients. The parents of Case 5 had normal immunoglobulin levels, but both the mother and father of Case 4 had γ M levels of 30 mg./100 ml. with normal γ G and γ A levels.

Positive Controls

Sera taken from four patients (A, B, C, and D) two to three weeks after the onset of meningococcal meningitis were kindly supplied by the Standards Reference Laboratory, Colindale, and were tested for meningococcal antibodies and immunoglobulin levels.

Normal Sera

Pooled serum from 10 mothers and pooled cord serum from their babies were tested for bactericidal action on meningococci under varying conditions. Cord serum contains half the adult level of haemolytic complement (Ewald *et al.*, 1961), has the same γ G content, but is deficient in γ A and γ M.

Idiopathic Isolated γ M Deficiency

Serum immunoglobulin levels were measured in over 3,000 miscellaneous hospital patients. Among 350 patients with deficiencies most had subnormal levels of γ G, γ A, and γ M all together. However, in 76 patients subnormal levels of γ M globulin occurred alone. In 47 of these the abnormality was thought to be secondary to pre-existing diseases such as myelomatosis, chronic lymphatic leukaemia, lymphoma, renal failure, idiopathic steatorrhea, etc. In 29 patients there was no known predisposition. Of these, 18 were asymptomatic, but among 11 who were symptomatic were three of the propositi (Cases 1, 2, and 4), two with pneumococcal meningitis, one with *Escherichia coli* meningitis, one with recurrent *E. coli* pyelonephritis, and four with mixed respiratory infections. Bacteraemia was proved in 10 of these 11 patients.

Methods

Immunoglobulin Measurements.—Immunoglobulin levels were measured by a modified Mancini method (Goldman and Hobbs, 1967). All sera were separated at 37° C. and when possible tested the same day to avoid loss of γ M. Aliquots were stored at -20° C, thawed once only for tests, and then discarded. Our own log-normal ranges are given for adults and throughout childhood in Tables I and II. In the families

of Cases 1 and 2 some sera showed low or borderline γ M levels. After ABO grouping of the red blood cells of such relatives of Case 1, isoantibody titres were measured as one way of assessing the quality of what little γ M globulin the subject had.

Meningococcal Antibodies.—Antibodies to meningococci were sought by the indirect fluorescence method. In Cases 2, 3, and 4 the organisms grown from the patient were tested against the patient's serum. Otherwise serum or C.S.F. was tested against four strains of meningococci—groups A and B, a non-groupable strain isolated from Case 2, and the strain isolated from Case 4. Air-dried smears of the organisms were exposed to the serum or C.S.F. to be tested, washed, then exposed to fluorescent rabbit antisera monospecific for human γ G, γ A, or γ M globulin and finally washed. Results were graded as negative (0) or positive (+, ++, +++). Rabbit γ -globulin fractions were conjugated to both fluorescein and lissamine rhodamine B200. The specificity and efficacy of the antisera had been verified many times on human myeloma marrow samples, etc.

Complement-fixation Tests.—Meningococci of groups A and B and of a non-groupable strain were grown as shake cultures in brain-heart infusion broth enriched with 20% horse serum. Antigens were extracted by a modified Price method (Ross and Stevenson, 1962), and complement fixation was tested as described by Ross (1961).

Bactericidal Activity of Sera.—Two pools of maternal and umbilical cord serum were treated by adsorbing lysozyme and β -lysin on to bentonite (Muschel and Jackson, 1966). Complement was inactivated by heating the serum to 56° C. for 30 minutes. The bactericidal activity of the unabsorbed, absorbed, and heated serum was tested by adding 3×10^5 meningococci to 1 ml. of serum and performing duplicate pour-plate counts at 5, 10, 20, 40, and 60 minutes thereafter.

Results

Table I summarizes the immunoglobulin levels and the results of meningococcal fluorescent antibody and complement-

fixation tests in the nine patients who suffered meningococcal infection. In the fatal cases (Nos. 1 and 2) and in the patient who survived (Case 4), the γ M serum levels were subnormal at the start of the illness, and in Cases 3 and 5 and the positive control A the γ M was low because they were only 2 months old. Case 4 had low serum γ A levels during the acute illness and convalescence. During convalescence γ G or γ M meningococcal antibodies appeared in the serum of survivors and a complement-fixation test was positive in Case 4 and all of the positive controls. In Case 5, the only patient from whom meningococci were not cultured, the nature of the bacterial meningitis was confirmed by the presence of γ M antibodies to meningococci in both serum and C.S.F. during convalescence. Neutropenia, commonly associated with septicaemia, was not present in the five *propositi* in whom phagocytosis appeared to be normal.

The family trees of the relatives of Cases 1 and 2 are shown in Figs. 1 and 2 respectively. The father, paternal uncle, and

First cousin	1½	900 (350–1,400)	<15 (30–120)	75 (50–170)			

paternal first cousin of Case 1 and the father of Case 2 had γ M levels more than 2 S.D. below our normal range (Table II) but were asymptomatic and had uneventful past histories. Two siblings of Case 1 and a sibling and first cousin of Case 2 had abnormally low serum γ A levels. Case 1 had a lower titre of ABO isoantibodies than his relatives with low γ M levels (Table II).

The bactericidal activity of normal serum to meningococci was investigated with pooled maternal or umbilical cord serum. The destruction of complement by heating removed bactericidal activity to meningococci. Fig. 3 shows that unadsorbed umbilical cord serum had a moderate bactericidal activity but that this disappeared after the adsorption of lysozyme and β -lysin. Maternal serum, on the other hand, had a much greater bactericidal activity, which was only slightly lessened after adsorption of the serum.

FIG. 3.—Bactericidal activity to meningococci of pooled maternal (squares) or cord serum (circles). Results from unadsorbed serum are shown by open symbols and from serum after bentonite adsorption by solid symbols.

Discussion

The observation that two boys who died from the Waterhouse-Friderichsen syndrome had a deficiency of serum γ M globulin led to an investigation of the role of γ M globulin as a humoral defence mechanism against meningococci. Neither of the boys died from acute adrenal failure, for plasma cortisol levels shortly before death were normal or raised. Neutropenia was not responsible for the rapid multiplication of meningococci, and in the case of Dr. Heist normal phagocytosis of meningococci was observed. It was postulated that the fulminating meningococcal septicaemia was due to a lack of bactericidal antibody and that death probably resulted from endotoxaemia or a generalized Schwartzman reaction. The post-mortem finding of fibrin occlusion of small vessels in Case 1 was in keeping with the view that death in a generalized Schwartzman reaction may be due to widespread intravascular coagulation (Skjörten, 1966).

Immunoglobulin levels and meningococcal antibodies were studied in three children admitted to hospital suffering from meningococcal meningitis and in the sera of four patients who were convalescing from meningococcal meningitis. None of the three children had meningococcal antibodies on admission to hospital, but γ M and/or γ G antibodies were detected in all

seven patients during convalescence. In a 2-month-old baby (Case 5) γ M meningococcal antibodies were found in the C.S.F. on the sixth but not on the first day after admission. Normally, γ M is not present in the C.S.F. (Schultze and Heremans, 1966), and the finding of C.S.F. γ M antibody in one patient suggested that the concentration had risen either as a result of active transport of γ M across the blood-brain barrier or, more likely, by secretion from cells which had migrated into the sub-arachnoid space. It was thought unlikely that γ M (mol. wt. 1,000,000) had entered the C.S.F. by simple diffusion, for it was present at half the serum concentration whereas γ G (mol. wt. 160,000) was present at one-fifth the serum concentration.

The detection of both γ G and γ M meningococcal antibodies prompted a study of the meningococcal activity of normal maternal and umbilical cord serum. The cord serum had the same γ G as the maternal serum but negligible amounts of γ A or γ M.

The meningococcal activity of both adult and cord serum was dependent on complement, but the activity of adult serum was not greatly affected by bentonite adsorption of lysozyme and β -lysin (Fig. 3). The weaker activity of cord serum was completely abolished after bentonite adsorption. This suggested that the meningococcal activity of adult serum did not reside in γ G globulin, and since fluorescence had failed to detect γ A antibodies the evidence favoured γ M as the site of meningococcal activity. Bactericidal antibodies against other Gram-negative organisms have been found mainly in the γ M fraction of the serum (Michael and Rosen, 1963; Evans *et al.*, 1966) and are absent in the γ A fraction (Adinolfi *et al.*, 1966).

Cohen and Norins (1966) demonstrated by immunofluorescent techniques that there were natural antibodies to *E. coli* and *Neisseria gonorrhoeae* in the γ A, γ G, and γ M fractions of normal serum and suggested that γ G antibodies had a critical role in the bacterial recognition system of the host. However, in a prospective study Sample *et al.* (1966) showed that prophylactic pooled human gammaglobulin (virtually only γ G globulin) offered no protection against the development of meningococcal meningitis and septicaemia.

In a study of the epidemiology of meningococcal infection more than 90% of Army recruits entering a training camp were found to become nasopharyngeal carriers of the endemic group B meningococcus (Brown and Condit, 1965). Despite the almost universal colonization of the upper respiratory tract of recruits entering an endemic area, only 1 in 400 got systemic disease, and of these only 10% had fulminating meningococcaemia. It is possible that the very small percentage of people who develop fulminating meningococcaemia lack an effective system for destroying meningococci in the blood stream which may be γ M globulin. The colonization of the nasopharynx by meningococci in most of the recruits suggests that γ A globulin, the immunoglobulin which normally protects mucus surfaces (South *et al.*, 1966), does not afford protection against meningococci. Our failure to detect γ A antibodies to meningococci is in keeping with this suggestion, which also lends support to the theory that meningococci gain access to the C.S.F. via the cribriform plate.

In the retrospective survey of immunoglobulin levels in over 3,000 hospital patients, 29 had an idiopathic isolated γ M deficiency. A third of these had proved bacteraemia, confirming the importance of γ M antibody in blood-stream defence. Further, pronounced increases in γ M levels occur in infections mainly confined to the blood stream such as malaria, trypanosomiasis (Mattern *et al.*, 1961), bartonellosis, and rickettsial endocarditis (Hobbs *et al.*, 1967b).

The discovery that the fathers of the two fatal cases and two male relatives of Case 1 also had γ M deficiency suggested that the abnormality might be inherited. This could offer an explanation of why Heist, whose blood had no meningococcal activity, and his five male relatives, all died of illnesses resembling cerebrospinal fever.

This isolated and severe γ M deficiency can be classified as a dysgammaglobulinaemia. It is distinct from the Giedion-Scheidegger variety (type 1), where γ A is also very low and where there is a continual history of all kinds of bacterial infections from birth. Case 4 initially showed a low γ A and γ M, but this may have been due to delay in immunological maturation, for both are now developing normally. Cases 1 and 2 are also distinct from the Wiskott-Aldrich syndrome (type VA), a sex-linked recessive condition usually fatal to affected males before 10 years of age, where though γ M deficiency appears it is usually associated with a marked increase of γ A. Clinically there is a long history of eczema, thrombocytopenia, and recurrent infections from soon after birth. Cases 1 and 2 have therefore been classified as type VB by Hobbs *et al.* (1967a). Furthermore, it is realized that isolated deficiency of γ M can be found in apparently healthy subjects (type VO) and can be associated with defects of other classes of immunoglobulins in both sexes of given families (Burtin *et al.*, 1964). Thus the finding of γ A deficiency in four other relatives of Cases 1 and 2 adds support to a genetic basis for their fatal abnormality.

Summary

Serum immunoglobulin levels and meningococcal antibodies were measured in nine patients suffering from meningococcal infection. The bactericidal activity of normal serum to meningococci could be attributed largely to γ M globulin. Severe γ M deficiency, probably inherited, was found in two boys dying from fulminating meningococcal septicaemia. Other evidence supported the view that γ M antibodies are an important humoral defence mechanism and that the normal

presence of these antibodies in the blood stream restrains systemic meningococcal infection to the C.S.F.

We thank Professor J. P. M. Tizard and Dr. J. A. Davis for allowing us to study patients under their care; Dr. S. Worledge, who estimated the blood groups and isoantibody titres; and Professor L. P. Garrod for his advice. Requests for reprints should be addressed to Dr. J. R. Hobbs, Department of Chemical Pathology, the Royal Postgraduate Medical School, Ducane Road, London W.12.

Access to Circulation by Permanent Arteriovenous Fistula in Regular Dialysis Treatment*

J. S. HANSON, M.B., B.SC.; M. CARMODY, M.B.; B. KEOGH, M.B.; W. F. O'DWYER, M.D.

Brit. med. J., 1967, 4, 586-589

Regular dialysis therapy has now become the accepted treatment of selected cases with end-stage renal disease.

Hitherto, repeated access to blood vessels for dialysis was achieved by means of the conventional Teflon or Teflon-Silastic prosthesis, establishing an external semipermanent arteriovenous shunt (Quinton *et al.*, 1960, 1962; Hegstrom, 1961). In spite of its considerable success this technique is far from perfect, and problems of infections and clotting remain as a major cause of trouble in the management of these patients. The average survival rate for external shunts varies considerably from one centre to another. In a series published from the Swedish Hospital in Seattle the mean shunt life for both arteries and veins varied from 11 days to 11.4 months (Murray *et al.*, 1964). In a more recent review from the same centre (Pendras and Smith, 1966) an average cannula survival of 12 to 14 months was reported. This they attributed to the prevention of infection in the patient before and shortly after operation, and also by avoiding cannulation in the severely uraemic state.

We have been unable to achieve a similar standard of shunt survival since we began regular dialysis therapy in November 1964. Our survival rates in arteries and veins were 3.8 and 3.6 months respectively, the majority of the failures occurring

in the first six weeks after surgery. The longest surviving shunt was 16 months. Infection and clotting, the major causes of our failures, were responsible for a high morbidity and often long periods of immobilization in hospital for surgical revision of the cannulas. This was particularly true for those in the lower limbs. The frequent manipulations involved in declotting were also a contributory factor to the psychological fixations which some of these patients developed about their cannulas. Our relative failure with the Quinton type shunt prompted us to adopt the surgically created arteriovenous fistula as described by Brescia *et al.* (1966). As a result of the arteriovenous fistula so created the arm veins are distended, allowing dialysis to be carried out by venepuncture. The veins are then in effect an extension of the arterial system.

Surgical Technique

Anaesthetic.—Brachial plexus block by the axillary route has been used routinely and has proved very satisfactory. Firstly, the accompanying sympathetic block dilates the blood vessels and prevents vascular spasm until the vein has been denervated by the stripping of its fascia. The sympathetic blockage may lead to free bleeding from the line of incision, but

* Department of Surgery and Renal Unit, Jervis Street Hospital, Dublin.

this can be controlled by circumvential infiltration around the wound with a local anaesthetic containing adrenaline. Secondly, the muscular paralysis enables the patient to lie in comfort with an outstretched arm for prolonged periods. Thirdly, the sensory effects of the brachial plexus block extends well into the postoperative period, and the analgesic effect is much appreciated by the patients. Fourthly, when performing this procedure under brachial block it is not necessary to admit the patient to hospital. Also it can be carried out at a time convenient to the patient and therefore does not interfere with his normal working hours.

Choice of Vessels and Site of Fistula Formation

In the early stages of this project we received patients who had had repeated shunt insertion. Frequently only ulnar arteries remained patent, the radial arteries having been cannulated. This does not make fistula formation impossible. Neither does it appear to impair seriously the blood supply to the hand if the sole remaining main vessel is used for fistula formation. In Tables I and II are given particulars of a series of 14 patients on regular dialysis treatment in whom an arteriovenous fistula was created surgically.

TABLE I.—Permanent Arteriovenous Fistula (A.V.F.) in Regular Dialysis Therapy

* Two successful repeats, opposite limb.

New patients introduced to the regular dialysis therapy programme cause no problem in respect of suitability of artery and vein, as they are initially fitted with a temporary Carmody (1964) type shunt, leaving a virgin arm for fistula formation. When available the radial artery and cephalic vein are used routinely, but, as mentioned, the ulnar artery and any superficial vein in close proximity may be used. Venae comitantes do not give the flow required in the superficial veins. When using an ulnar artery it is preferable to avoid use of the small superficial veins in the area of the skin creases on the ventral carpal surface. In this situation the skin is tethered to the deep fascia, making dissection difficult and increasing the possibility of vessel spasm due to excessive handling. Again, the veins in this area form a branching network; therefore without ligating some branches it is unlikely that a segment of vessel adequate for fistula formation will be obtained. Finally, in association with brachial block there appears to be more superficial bleeding in the area.

In choosing a suitable vein a venous tourniquet is applied and the arm inspected. The availability of a suitable vein really dictates the site of fistula formation, but it is desirable to create it as far distally as possible in the arm to facilitate future venepuncture and tourniquet application. The depth

of the artery from the surface does not militate against the use of a suitable vein.

A transverse incision is used routinely. Longitudinal incisions have to be of greater length to provide adequate exposure; also, they heal badly. The incision is made at the point of nearest proximity of artery and vein, unless the vein has an excessive number of branches in the area. A segment of vein without branches and sufficient for an anastomosis is necessary, as it is desirable to leave as many patent tributaries as possible. In the virgin arm the cephalic vein is constant in position and generally of good calibre, but in patients who have repeated shunt insertion and intravenous therapy most subcutaneous veins may be occluded. With an adequate cross anastomosis, veins that are quite minute enlarge and it seems that large thrombosed veins may recanalize. The skin incision should be of sufficient size to ensure that an adequate segment of vessel may be mobilized without tissue distortion due to retraction. Caution must be exercised to limit the incision to skin only, as otherwise the veins in the superficial fascia may be severed.

When the skin has been incised the superficial fascia is opened as far as the lateral margin of the vein on both sides. The skin and superficial fascia are undermined on both sides of the wound, leaving the vein encased in its own fascia. A venous tourniquet is applied to dilate the vein. The fascia on the vein is incised down to the adventitial layer at a central point and a sling is positioned here. From this point the vein is cleared by sharp dissection. Once the correct plane has been entered it is quite easy to clear the vein. To ensure maximum mobilization adjacent tributaries are cleaned in similar fashion. Another sling is now inserted and the vein is swung to the area of the artery, indicating the degree of mobility and adequacy of dissection. The vein lies in superficial fascia. In order to achieve approximation with the artery it must be slung deep to the fascia. This makes adequate undermining of the fascia a matter of paramount importance if "kinking" of the vein is to be avoided.

It must be emphasized that the completed arteriovenous fistula will be between deep and superficial fasciae, and "kinking" may occur at the junction of dissected and undissected segments of the vein. The tourniquet is now released, there being no danger of vessel spasm in the segment of vein to be used. The fascia over the artery is incised longitudinally. At one point the artery is freed from the venae comitantes and the sling inserted round the artery; the artery is dissected free. Only tributaries that will definitely interfere with its mobility are cut and tied. A second sling is inserted. With the use of both sets of slings, artery and vein are approximated (Fig. 1). The vessels must lie parallel for a distance of at least 2.5 cm. between slings without tension or angulation if adequate fistula

FIG. 1.—Vessels dissected and approximated. Use of slings indicating adequacy of dissection.

formation is to be obtained. This is a critical point, as an equal flow in the vein, both proximally and distally, will otherwise not be obtained. Where the artery leaves and enters its own proper tissue plane an edge of fascia remains; this may "kink" the artery. It may therefore be necessary to extend the fascial incision proximally and distally. Both sets of slings are now replaced with De Bakey peripheral arterial clamps. These clamps are introduced from the assistant side. Longitudinal incisions 0.5 cm. in length are made in corresponding lateral surfaces of vein and artery (Fig. 2). The lumen of both vessels is washed out with heparinized saline and a side-to-side anastomosis made in continuous fashion with 00000 polyethylene (Fig. 3). On release of the clamps there is an immediate bruit and thrill. The wound is sutured in two layers.

FIG. 2.—De Bakey clamps in position before suturing.

FIG. 3.—Arteriovenous fistula completed.

Management

Postoperative Care.—We feel it is necessary to use prophylactic antibiotics for five days after the operative procedure. It is essential that patients are well dialysed before operation, as this greatly lessens the hazard of infection. To allow healing and vein distension the fistula is not used for seven days.

Dialysis Technique

Previous to venepuncture a tourniquet is applied to the upper arm to obtain venous engorgement. The puncture sites are

infiltrated subcutaneously with 0.5% lignocaine without adrenaline. Initially the obtaining of a suitable puncture needle was a major problem. We tried a variety of needles, but were continuously faced with the problem of clotting of the needles in the lumen despite increasing the standard dose of heparin by 10,000 units. However, we realized that the quality of our needles was at fault, the surface of the inside of the lumen being rough. We now satisfactorily use a 1½-in. (3.8-cm.) 14 gauge thin-walled smooth-bore needle (Bardic). The needles are attached to Tomac extension tubes (Fig. 4). Firstly, the return-flow needle is inserted cephalically below the antecubital fossa and advanced maximally. The tourniquet is released and the standard dose of heparin is infused through this needle. Adequate time for heparinization is allowed. The tourniquet is now reapplied below the proximal needle and the outlet venepuncture is performed. If the needle is inserted proximal to the fistula it should be directed towards the hand, while if inserted distally it should point cephalically. The predialysis blood samples are taken from this latter tube.

FIG. 4.—Needles in situ—dialysis in progress.

A light venous tourniquet is occasionally necessary between the needle insertions to ensure adequacy of flow. This is particularly so in the first few weeks after fistula formation, but later is unnecessary as the veins become distended and arterialized. Blood flow rates of 300 ml. per minute are easily obtainable by means of a roller type blood pump. Each dialysis lasts nine hours, and there is no falling off in the blood flow rates. At the completion of dialysis, protamine sulphate is infused. Each needle is removed at intervals of 10 minutes and digital pressure is applied by the patient along the line of venepuncture until haemostasis is obtained. This requires three to five minutes on an average. A light dressing is applied to the puncture sites, and the patient discards it after a few hours.

Comment

On our dialysis programme we use Kolff twin-coil machines, similar to those used by Brescia *et al.* (1966), who pioneered this technique of access to the circulation. In order to maintain an adequate flow rate with this technique some form of pump on the "arterial" side is necessary. Therefore the technique is not suitable for use on patients dialysed on a conventional Kiil type machine. In our experience with the external arteriovenous shunt (Quinton-Scribner) we must admit that our earlier regular dialysis therapy patients were inadequately dialysed owing to very demanding acute renal failure commitments. For the past eight months we have been able to correct this, and we recognize that inadequate frequency of dialysis may have increased our incidence of clotting and infection in the original external shunts. We are none the less impressed, however, by the Brescia-Cimino fistula, which allows much greater comfort and freedom for the patient. One woman on our programme has taken up golf since discarding her external shunt for the fistula.

Since we adopted this method of access to the circulation for haemodialysis, the morale of each patient has changed considerably. Patients no longer live with their fears of an artificial Teflon shunt with its possible hazards and complications. They can rehabilitate themselves more easily and their lost working hours have decreased considerably. Similarly, life for members of the staff is no longer punctuated by frustrating crises of clotted shunts and infection.

We have not observed any evidence of cardiac embarrassment in spite of the alteration in circulatory dynamics produced by the introduction of the arteriovenous fistula.

We would like to suggest that this technique might be of value in circumstances other than haemodialysis where repeated access to the circulation is required—for example, repeated transfusions in aplastic anaemia. In this regard Williams *et al.* (1967) and Anderson *et al.* (1967) have reported on the successful use of the conventional type of Quinton-Scribner Teflon shunt in a total of three patients with aplastic anaemia requiring regular transfusions. It is noted, however, that in two cases the problem of clotting occurred. From our experience we would suggest that a permanent surgically created arteriovenous fistula as described here would be a less troublesome method of obtaining access to the circulation when repeated transfusions are required.

Summary

An arteriovenous fistula was created surgically in 14 patients on regular dialysis treatment in order to provide repeated access to the circulation. In 11 patients the initial arteriovenous fistula functioned satisfactorily and without complica-

tions. In two patients in whom the initial fistula failed to function, success was achieved in the opposite forearm. In one patient in whom the procedure failed initially a second attempt to create a fistula has been postponed owing to the poor calibre of her veins and the urgency of maintaining adequate haemodialysis.

ADDENDUM.—Since this communication was submitted for publication two further patients have had successful arteriovenous fistulas established. In addition one patient (Case 9) in whom arteriovenous fistula formation on 31 January 1967 was unsuccessful and in whom a Quinton shunt was replaced has recently had a functioning fistula established by use of her remaining ulnar artery. In September 1967 the total number of patients with successful fistulas was therefore 16.

Thyrocalcitonin Deficiency after Treatment of Thyroid Disorders by Surgery or Radioiodine

R. N. SMITH,* M.B., CH.B., B.SC., M.R.C.P.ED., D.OBST.R.C.O.G.; H. C. K. LALJEE,† M.B., CH.B., B.SC., M.R.C.P.ED.

Brit. med. J., 1967, **4**, 589–591

The isolation of thyrocalcitonin from human thyroid tissue (Hirsch, Voelkel, and Munson, 1964; Milhaud, Moukhtar, Bourichon, and Perault, 1965; Smith, Laljee, and Dorrington, 1966; Aliapoulos, Voelkel, and Munson, 1966; Tashjian, Frantz, and Lee, 1966; Mazzuoli, Coen, and Baschieri, 1966; Laljee, Smith, and Dorrington, 1967) and the demonstration of its hypocalcaemic action in man (Foster, Joblin, MacIntyre, Melvin, and Slack, 1966; Bell, Barrett, and Patterson, 1966) have stimulated interest in the importance of this hormone in human physiology.

High serum calcium levels stimulate the release of thyrocalcitonin (Foster, Baghdiantz, Kumar, Slack, Soliman, and MacIntyre, 1964; Care, 1965). If the calcium-lowering effect of this hormone was absent the serum calcium might rise higher and fall more slowly after an intravenous calcium load in comparison with a normal response. Deficiency of thyrocalcitonin might occur after removal or destruction of most of the thyroid gland, as may occur after surgery or radioiodine therapy. This possibility has been investigated by studying the response of patients to an intravenous calcium infusion (Smith and Laljee, 1967).

Patients and Methods

Subtotal Thyroidectomy Group.—Patients received intravenous calcium infusions two or three days before and at the same interval after subtotal thyroidectomy for thyrotoxicosis (five) or non-toxic goitre (four); thus each patient acted as his own control. Antithyroid drugs and potassium iodide were given preoperatively to patients with thyrotoxicosis.

Radioiodine Therapy Group.—Our studies included 24 patients who had been treated with radioiodine for thyrotoxicosis from 2 to 15 years previously and a group of seven patients of similar age without any evidence of thyroid disorder who agreed to help in this investigation after its value had been fully explained to them.

Technique.—The intravenous infusion of calcium was given at a constant rate over four hours by means of a D.C.L. micro-pump type T (Messrs. F. A. Hughes & Co. Limited). The dose of elemental calcium was 15 mg./kg. body weight given as a calcium gluconate solution (15 mg. of calcium per 5 ml.). Blood samples were taken before (0 hours) and immediately after the infusion (4 hours), and subsequently at 8, 12, and 24 hours. The serum calcium was estimated by an edetic acid titration with calcichrome as indicator and a manual titrator (Messrs. Evans Electroselenium Ltd.). The rise in serum calcium and elevation above pre-infusion level was plotted at four-

* Lecturer in Pharmacology and Therapeutics, University and Royal Infirmary, Sheffield.

hourly intervals up to 12 hours. The area beneath the graph was calculated, and it represented the response to the calcium infusion (Fig. 1).

FIG. 1.—Representation of response to four-hour calcium infusion and calculation of the area below the curve of serum calcium values.

Results

Subtotal Thyroidectomy.—There was no significant difference between the preoperative and postoperative responses to the calcium infusion in nine patients (Fig. 2). No difference was apparent between the patients with thyrotoxicosis and those

FIG. 2.—Responses to calcium infusion. O = Euthyroid patients. ● = Hypothyroid patients on thyroxine. ▲ = Mean value of each group. H = Hypothyroidism developed six months later.

Details of Patients and the Response After Intravenous Calcium Infusion

Groups	No. Studied	Mean Age ± S.D.	Mean Serum Calcium Values (mg./100ml.) ± S.E.		Mean Area of Graph ± S.E.
			Before Infusion (0 hours)	Rise After Infusion (4 hours)	
Subtotal thyroidectomy:					
1. Thyrotoxicosis:					
Before operation	5	37 ± 5	9.84 ± 0.24	4.59 ± 0.44	27.65 ± 1.56
After operation			9.44 ± 0.20	4.59 ± 0.55	28.75 ± 3.8
2. Simple goitre:					
Before operation	4	46 ± 5	9.85 ± 0.09	4.46 ± 0.51	28.08 ± 3.52
After operation			9.05 ± 0.12	3.92 ± 0.61	28.55 ± 5.6
Radioiodine therapy:					
1. Euthyroid	8	62 ± 7	10.49 ± 0.12	6.54 ± 0.36	43.17 ± 2.05
2. Hypothyroid on thyroxine	16	59 ± 7	9.96 ± 0.15	5.61 ± 0.37	38.80 ± 2.71
Control	7	55 ± 5	9.77 ± 0.34	4.58 ± 0.73	30.13 ± 4.28

with non-toxic goitres (see Table). Three patients had higher calcium levels postoperatively after the infusion compared with their preoperative values. Two became hypothyroid six months after the operation (indicated by H in Fig. 2); the other had a large multinodular goitre. The small portion left appeared grossly disorganized, and accordingly the patient was started on thyroxine immediately after operation.

Radioiodine Therapy.—The response to calcium infusions in 24 patients after radioiodine therapy (Fig. 2) differed significantly from both the preoperative and postoperative surgical groups ($P < 0.005$) and the control group of similar age ($P < 0.05$). There was a positive correlation ($r = +0.50$, $P < 0.02$) between the response to the calcium load and the time interval since the irradiation of the thyroid (Fig. 3). No correlation was apparent in the radioiodine group when the results were plotted in relation to the age of the patients or the total dose of calcium administered.

Discussion

Intravenous calcium infusions were used to assess thyrocalcitonin secretory capacity because the release of this hormone is stimulated by high serum calcium levels and its calcium-lowering action corrects experimental hypercalcaemia (Foster *et al.*, 1964). It does not influence renal excretion of calcium directly but acts by inhibiting the resorption of bone (Friedman and Raisz, 1965; Milhaud *et al.*, 1965; Aliapoulos and Munson, 1965; Gaillard, 1966; Foster *et al.*, 1966; Johnston and Deiss, 1966). The most sensitive measurement of its action is the serum calcium level. The greater rise of

FIG. 3.—Correlation of response to calcium infusion represented by area below serum calcium curve and time interval (months) since radioiodine therapy ($r = +0.50$, $P < 0.02$).

serum calcium and the persistence of elevated readings after intravenous calcium loading are consistent with a deficiency of thyrocalcitonin.

Surgical and radioiodine treatment of thyrotoxicosis may damage the parathyroids (Adams and Chalmers, 1965), but there was no clinical or biochemical evidence of this in our patients. In fact, parathyroid damage would not influence the speed of recovery from hypercalcaemia after calcium loading (Hahnemann and Friis, 1965). Hypothyroidism will alter the response to a calcium infusion (Krane, Brownell, Stanbury, and Corrigan, 1956; Lowe, Bird, and Thomas, 1962). Our patients were all euthyroid, including those with post- ^{131}I hypothyroidism who were on adequate replacement doses of thyroxine.

The effect of subtotal thyroidectomy on the response to an intravenous calcium load was insignificant in most cases. These

patients were left with an amount of thyroid tissue thought to be sufficient to keep them euthyroid. However, two patients who became hypothyroid six months later did not lower the calcium level so efficiently as others in this group. The other patient with a defective response had a radical excision of a multinodular gland, and the tissue left was severely deranged. In these three patients little or no active thyroid tissue was left in the body. In pigs and in rats similar results were found after total thyroidectomy (Care, Duncan, and Webster, 1967; Gittes and Irvin, 1965). Similar calcium infusion studies on 14 patients who had subtotal thyroidectomies have shown defective handling of the calcium load in five (Hahnemann and Friis, 1965). In other infusion studies four out of seven hypothyroid patients receiving thyroxine had delay in return to preinfusion calcium levels (Williams, Hargis, Galloway, and Henderson, 1966). Finally, Ibbertson, Roche, and Pybus (1967) have shown failure to lower promptly the serum calcium after an infusion of calcium in patients with spontaneous hypothyroidism when on thyroxine.

Antithyroid medication has been reported to reduce the release of thyrocalcitonin in pigs (Duncan and Care, 1967), and the glands have a higher thyrocalcitonin content (Care, Duncan, and Webster, 1966). Our studies showed no difference in the response of patients with thyrotoxicosis, who had antithyroid drugs, and patients with non-toxic goitres or those who had no thyroid disorders. Our patients did not have high doses of antithyroid drugs, whereas the pigs had relatively large doses, resulting in considerable gland hyperplasia and hypothyroidism. The latter can produce an abnormal response to a calcium load. Parallel studies of thyroid tissue from patients treated preoperatively with antithyroid drugs in doses sufficient to control their symptoms have not shown any increase in the thyrocalcitonin content of these glands compared with tissue from patients with non-toxic goitres and necropsy thyroid tissue (Laljee *et al.*, 1967). It seems unlikely, therefore, that thyrocalcitonin release was inhibited by the doses of antithyroid drugs given to our patients, and this medication would still be effective two to three days after the operation.

Radioiodine therapy damages thyroid tissue extensively, leading to progressive loss of function due to impairment of cell division. Experience has shown that in many patients hypothyroidism develops insidiously many years after radioiodine therapy (Beling and Einhorn, 1961; Green and Wilson, 1964; Dunn and Chapman, 1964; Nofal, Beierwaltes, and Patno, 1966). Thyrocalcitonin production may similarly fail after thyroid irradiation, and our results suggest that this is also time-dependent. The defective response was independent of the age of the patient.

It is probable that thyrocalcitonin production is deficient in some patients after thyroid surgery or radioiodine therapy owing to factors which are similar to those that result in hypothyroidism. The evidence presented suggests that thyrocalcitonin deficiency can be demonstrated by challenging the thyroid with a calcium load before hypothyroidism is manifest. Furthermore, in patients treated with radioiodine thyrocalcitonin deficiency is time-dependent, but it may precede or follow the onset of hypothyroidism.

Summary

Intravenous calcium infusions were administered to patients treated by surgery or radioiodine for thyroid disorders in order

to assess whether these radical procedures had resulted in a deficiency of thyrocalcitonin.

A defective response to a calcium load was observed in three out of nine patients after thyroid surgery; they had suffered extensive removal of thyroid tissue. In 24 patients treated for thyrotoxicosis by radioiodine a progressive decrease was demonstrated in the response to a calcium load with the passage of time after irradiation. The failure to handle the calcium load efficiently in these patients who have had extensive removal of or damage to the thyroid tissue has been interpreted as evidence of thyrocalcitonin deficiency.

This work was supported by the United Sheffield Hospitals Endowment Fund, by a University Research Fund Grant (R.N.S.), and a Boots Research Grant (H.C.K.L.). The advice and encouragement of Professor G. M. Wilson and Professor D. S. Munro were invaluable. We are grateful for the co-operation of Mr. C. H. Talbot, who performed the operations, and of Mr. A. Young, Dr. K. H. Hardy, and Dr. A. J. Smith, who gave us the opportunity to include patients under their care. We wish to thank Miss Sandra Taylor for her technical assistance and our house-physicians, who have kindly taken the evening blood samples on many occasions.

Long-term Trial of Local Guanethidine in Treatment of Eye Signs of Thyroid Dysfunction and Idiopathic Lid Retraction

A. L. CROMBIE,* M.B., CH.B., F.R.C.S.ED.; A. A. H. LAWSON,† M.B., CH.B., M.R.C.P.ED.

Brit. med. J., 1967, 4, 592-595

The advent of adrenergic blocking agents has provided a new tool in the treatment of the eye signs of thyroid dysfunction and idiopathic lid retraction. The increasing availability of local ophthalmic preparations of these drugs has resulted in the trial of some of them in the treatment of these distressing eye conditions. For example, Lee, Morimoto, Bronsky, and Waldstein (1961) described the therapeutic use of local phentolamine, and Sneddon and Turner (1966) and Gay and Wolkstein (1966), in almost simultaneous communications, reported favourably on the short-term use of local guanethidine (Ismelin). Sneddon and Turner (1966) also reported on the effects of conjunctival administration of the β -adrenergic blocking agent propranolol, and Gay, Salmon, and Wolkstein (1967) have suggested that local bethanidine may also be of value.

In a short-term study, comparison between the effect of local guanethidine and propranolol eye-drops on thyrotoxic lid retraction and lid lag was made by Sneddon and Turner (1966). They concluded that local guanethidine was the more effective drug for this purpose. A similar conclusion regarding the value of guanethidine was reached by us (Crombie and Lawson, 1967) in a double-blind cross-over trial which compared the effects of bretylium, bethanidine, guanethidine, propranolol, and debrisoquine. In short-term use guanethidine was also least likely to cause significant side-effects.

A long-term trial of local guanethidine in the treatment of the eye signs of thyroid dysfunction and idiopathic lid retraction is reported here.

Patients and Methods

Twenty patients were studied, four males and 16 females (Table I). The thyroid status of all these patients was assessed by clinical examination, estimation of the serum protein-bound

TABLE I.—Thyroid Status of Patients During Period of Study

Primary Diagnosis	Thyroid Status During Study	Patients		Current Treatment		Previous Treatment ¹³¹ I
		M.	F.	Carbimazole	Thyroxine

	Mild thyrotoxicosis		2	2		
Hypothyroidism	Euthyroid		1		1	
Idiopathic lid retraction	"		3			

iodine, and a four-hour uptake of ¹³¹I. Thyroid function in each case was maintained at a stable level throughout the period of study. Sixteen patients were known to have been thyrotoxic previously, and 14 of these remained euthyroid throughout this study on the treatment indicated (Table I). Four of these 14 patients were controlled on thyroxine because of hypothyroidism after ¹³¹I treatment. Two patients remained mildly thyrotoxic in spite of carbimazole therapy. Of the remaining four patients

one was euthyroid while on treatment with thyroxine for primary hypothyroidism and three, classified as cases of idiopathic lid retraction, showed no evidence of thyroid dysfunction at any time. All of the patients had eye signs of thyroid disorder to a greater or less degree, and these had been present for periods of up to four years (Table II).

18			+		+				2 years
19	+	+	+		+				1 year
20	+	+			+	+	+	+	1 year

Each patient was examined at weekly intervals to begin with and then at longer intervals, depending on the presence or absence of side-effects. The average duration of the trial was 16 weeks, with a range from 6 to 26 weeks. At each visit subjective symptoms, including the subjective effects noted on instilling the preparation, were recorded; systemic blood pressure was measured in the erect and supine positions, and examination of the eye, which included external examination, with particular reference to the conjunctiva, cornea, and eye movements, was performed. The ocular fundi were studied and visual acuity and refraction measured. Exophthalmometry (Hertel) was undertaken and an estimation was made of the pupil diameter, palpebral aperture, and, in 11 of the subjects, intraocular pressure by means of both Schiötz and Goldman's applanation tonometers. Both the pupil diameters and the palpebral apertures were measured directly under constant illumination in the mid-palpebral line, with the patient fixing on a point source of light 6 metres distant. The eyes were photographed before starting treatment and after six weeks of continuous treatment. Guanethidine sulphate 10% eye-drops in a buffered solution of methylcellulose were used, one drop in each affected eye twice daily being the standardized dosage.

Results

Results are shown in Table III.

Subjective Symptoms.—With the exception of two patients (Cases 15 and 19) all of the subjects felt that guanethidine had

* Senior Registrar, Professorial Unit, Eye Department, Royal Infirmary, Edinburgh.

† Lecturer, University Department of Medicine, Western General Hospital, Edinburgh.

been of benefit to their eyes. One of these two patients (Case 15) developed an acute local sensitivity to guanethidine six weeks after starting the drug and treatment had to be stopped. Before treatment 10 patients complained of a feeling of grittiness in their eyes, and on guanethidine therapy 9 of these 10 experienced either an improvement or disappearance of this symptom. No patient complained of dizziness, and in all cases measurements of systemic blood pressure both erect and supine did not change significantly from the pretreatment figures.

TABLE III.—Changes in Eye Features After Local Guanethidine Treatment

	Number of Patients			
	Total	Improved	Un- changed	Deterio- rated
Subjective symptoms	20	18	2	
Systemic blood pressure	20		20	
Conjunctival oedema	14		14	
Conjunctival injection	12	3	7	2
Periorbital oedema	6	4	2	
Ophthalmoplegia	9		9	
Lens and fundus	20		20	
Refractive error	20		20	

Conjunctival Oedema.—Guanethidine therapy did not seem to influence the presence or absence of conjunctival oedema, which was present in 14 of the patients.

Conjunctival Injection.—Twelve patients had conjunctival injection at the beginning of the trial. On guanethidine therapy no significant change was noted in seven of the patients, three improved, and two became worse. The increased hyperaemia observed in these last two patients was, however, mild and did not prevent continuation of treatment.

Periorbital Oedema.—Six patients (Table II) had considerable periorbital oedema and in four of these (Cases 5, 10, 12, and 20) a marked decrease in the amount of oedema occurred a short while after guanethidine therapy was instituted. No change in the amount or distribution of periorbital oedema was noted in the other two patients.

Ophthalmoplegia.—No improvement in the field of action of any involved extraocular muscles was noted.

Lens and Fundus.—No change was noted in the lens and fundus of any patient on guanethidine therapy.

Refractive Error.—No changes occurred in the refractive errors of any of the patients while on guanethidine therapy.

Palpebral Aperture

The results are shown in Table IV. Lid retraction was markedly relieved or abolished in all nine patients who showed a reduction in palpebral aperture greater than 20%.

TABLE IV.—Changes in Palpebral Aperture

Eye Signs Before Treatment	No. of Patients	Percentage Reduction in Palpebral Aperture			
		≤ 10	11–20	21–30	> 30
Lid retraction f Unilateral ..	6	2		2	2
present Bilateral ..	7	1	1	4	1
No lid retraction	7	3	4		

Six patients (Table II) with predominantly unilateral lid retraction were treated on the affected side only. In two (Cases 15 and 19) there was only 1 mm. (8%) reduction in the width of the palpebral aperture. Of the other four patients in this group, two (Cases 7 and 17) showed a narrowing of 3 mm. (20–24%) and two (Cases 11 and 18) of 4 mm. (31–33%). No change was noted in the untreated eye in any of these patients (Fig. 1).

In the group of seven patients with bilateral lid retraction (Table II) one patient (Case 12) showed a narrowing of the

palpebral aperture of only 1 mm. (9%) in both eyes, and another (Case 4) obtained 2 mm. (17%) reduction in each eye. The remaining five patients (Cases 1, 2, 3, 14, and 20) derived greater relief of lid retraction, the reduction in palpebral aperture ranging from 21 to 27%. This reduction in width was symmetrical in three (Cases 3, 4, and 12), greater in the right eye in two (Cases 14 and 20), and greater in the left eye in the remaining two (Cases 1 and 2). The reduction in width of the palpebral apertures was of great cosmetic value to the patients with lid retraction (Fig. 2).

The changes in lid aperture observed in the seven patients without significant lid retraction were less marked, the reduction being on the average 12.7% (range 6–18%). None of these patients developed unsightly ptosis.

FIG. 1.—Case 18. Patient with unilateral idiopathic lid retraction. Above, before treatment. Below, after six weeks' local guanethidine (10%) to the right eye alone.

FIG. 2.—Case 14. Above, patient's appearance before treatment. Below, after six weeks' local guanethidine (10%).

Pupils

Meiosis occurred in all the treated eyes except in two patients. The pupil diameter never became less than 2 mm. and the pupil remained reactive to light and accommodation. No restriction in the field of vision was noted by any of the patients, and in 10 of the 20 patients the visual acuity improved by one line on the Snellen chart, irrespective of the refractive error present.

Exophthalmos

Bilateral exophthalmos was present in 11 of the patients. In another seven it was mainly unilateral and in the remaining two was not thought to be a significant eye sign. Exophthalmometer readings decreased by 3 mm. (14–18%) bilaterally in two patients (Cases 1 and 10) and by 4 mm. (16%) in the treated eye of a patient (Case 14) with unilateral exophthalmos (Fig. 2). In another patient (Case 2) the decrease was remarkable, being in the region of 10 mm. (25%) in each eye (Fig. 3).

FIG. 3.—Case 2. Above, before treatment. Below, after six weeks' local guanethidine (10%).

Intraocular Pressure

The results are shown in Table V. With the exception of one patient (Case 4), all of the 11 patients in whom measurements of intraocular pressure were made were found to have reductions in pressure after guanethidine treatment. In four patients (Cases 2, 10, 12, and 20), all of whom had moderate proptosis, the intraocular pressures before guanethidine therapy were over 21 mm. Hg, measured on the Goldmann applanation tonometer, on more than one occasion. Schiøtz tonometry

TABLE V.—Changes in Intraocular Pressure in 11 Patients While on Local Guanethidine Treatment

Intraocular Pressure (I.O.P.) Before Guanethidine	No. of Patients	Percentage Increase in I.O.P. ≤ 10	Percentage Decrease in I.O.P.			
			≤ 10	11–20	21–30	> 30
≤ 21 mm. Hg	7	1	1	2	2	1
> 21 mm. Hg	4			2	1	

consistently underestimated the intraocular pressure in these cases. In the other seven patients intraocular pressures were 21 mm. Hg or below. While on guanethidine therapy the intraocular pressure fell on an average by 4 mm. Hg in the first week and did not fall thereafter. In one patient (Case 4) a rise of 2 mm. Hg occurred in both eyes on guanethidine therapy, and this slightly raised level of intraocular pressure remained unchanged while he was on treatment.

Side-effects

The toxic effects of local guanethidine are shown in Table VI. Three patients complained of mild nasal congestion while on treatment and one complained of an unpleasant metallic taste a short while after administration of the drug. One patient developed an acute local sensitivity reaction to 10% guanethidine after six weeks' therapy and the drug had to be discontinued. Ten of the patients complained of brief local irritation on instillation of the drug. These complaints of pain on instillation of the drops were mild and of little consequence in themselves, but all of these 10 patients subsequently developed a superficial punctate keratitis in their treated eyes usually affecting the lower half of the cornea. The keratitis developed after one week's treatment in four cases, after three to four weeks in another two, and after seven to eight weeks in the remaining four. The keratitis was bilateral in five cases and unilateral in five, the unilateral group including three patients who were receiving therapy to one eye only. Three cases were very mild and the keratitis did not increase in severity even though treatment was not discontinued. Treatment was discontinued in the other seven cases, and within one week the keratitis had disappeared without further treatment. When guanethidine 10% was again administered to these patients the keratitis usually reappeared within five to seven days, disappearing again when the guanethidine 10% was stopped, though the lid retraction recurred within 48 hours of discontinuation.

TABLE VI.—Side-effects of Local Guanethidine Treatment in 20 Cases

Nasal congestion	3	Local irritation on instillation ..	10
Unpleasant taste	1	Superficial punctate keratitis ..	10
Local sensitivity	1	No side-effects	10

Because of this effect of the guanethidine 10% solution, guanethidine 5% drops were substituted during the last two to four weeks of the trial. The keratitis improved markedly on this therapy; and it had disappeared in seven of the nine cases within seven days and in the other two cases within 14 days. The other effects of the 5% guanethidine drops were not as marked as when the 10% solution was used, in that on average the palpebral apertures were 1 mm. wider and the pupil diameter 0.5 mm. greater. On the other hand, the improvements in intraocular pressures were maintained, as was the subjective relief of symptoms.

Discussion

The results of this trial indicated that improvement in the eye signs associated with thyroid dysfunction after the short-term use of guanethidine reported previously (Sneddon and Turner, 1966; Gay and Wolkstein, 1966; and Crombie and Lawson, 1967) can be maintained when the drug is used for longer periods and that this therapy is also of value in cases of idiopathic lid retraction. On discontinuation of the drug a return of signs and symptoms occurred within 48 hours, irrespective of the previous duration of guanethidine therapy. In contrast to Gay and Wolkstein (1966) this study indicated (1) that in most cases treatment for one week with guan-

ethidine 10% will achieve maximum results—only 2 of the 20 patients in this trial showed any further improvement in signs and symptoms after the initial seven days' therapy; and (2) that the response to guanethidine appeared to have little relation to the thyroid status at any one time or in any one individual.

It is also of interest that, in this limited study, 4 patients out of 10 with bilateral exophthalmos for a year or more had an intraocular pressure of over 21 mm. Hg on more than one occasion. In all these cases Schiøtz tonometry gave false low readings compared with applanation tonometry. Guanethidine 10% caused a reduction in the increased intraocular pressure in these four cases, the effect being more pronounced the higher the initial intraocular pressure. Guanethidine 5% maintained this reduction in intraocular pressure in each case. No mention of side-effects was made by Gay *et al.* (1967) in relation to the long-term use of guanethidine. One patient in our trial developed an acute skin-sensitivity reaction to guanethidine after six weeks' therapy. In a separate series of 10 patients treated with guanethidine for chronic simple glaucoma, two developed this type of reaction after six and eight weeks' therapy respectively. That the reaction was due to guanethidine was not in doubt, since it occurred again when guanethidine 2.5% drops were used.

In this trial 50% of patients developed a superficial punctate keratitis after one to eight weeks' therapy, unrelated to corneal exposure and relieved by discontinuing treatment, which was done in 7 of the 10 patients involved. There seems little doubt that this complication was due to guanethidine 10%, since it reappeared on resumption of therapy with this concentration of guanethidine. No cases have been reported of punctate keratopathy due to methylcellulose, the vehicle in this case, and corneal exposure could not be implicated, since lid retraction returned on discontinuation of the therapy yet improvement in the corneal condition occurred.

In the trial mentioned above, in which guanethidine 10% was used to control chronic simple glaucoma, two identical cases of superficial punctate keratitis occurred after approximately four months' therapy. A point of speculation raised by these results is whether the cornea in patients with thyroid dysfunction is more susceptible than the normal cornea to a punctate keratitis when guanethidine 10% therapy is in use. One of the three patients, however, with idiopathic lid retraction and normal thyroid function also developed a punctate keratitis. Oosterhuis (1962) and Gay and Wolkstein (1966) reported an increase in conjunctival injection on guanethidine (10%) therapy. In our study there was no relation between conjunctival injection and the development of punctate keratitis. It seems unlikely, therefore, that the increase in conjunctival injection reported in these previous communications was associated with corneal damage. The absence of superficial punctate keratitis when using guanethidine 5% was most

striking, and this would seem to be a safer and yet equally effective concentration.

Where topical guanethidine is to be used in the treatment of lid retraction syndromes the following precautions are advisable: (1) guanethidine 5% should be used initially in all cases, and only where it is unsatisfactory should a 10% solution be considered; (2) a close watch by an ophthalmologist on the treated eyes is essential; and (3) raised intraocular pressure should be looked for in all cases of exophthalmos, since in some patients with this condition the rise in pressure may be pronounced, with danger of ultimate impairment of vision.

Summary

A long-term trial of local guanethidine in the treatment of the eye signs associated with thyroid dysfunction and idiopathic lid retraction was undertaken in 20 patients (4 males and 16 females).

Subjective benefit was obtained in 18 patients. Nine out of 10 patients who had had troublesome "grittiness" experienced great improvement in or complete disappearance of this symptom on guanethidine treatment.

Other benefits obtained included reduction in lid retraction, periorbital oedema, exophthalmos, and raised intraorbital pressure, where these abnormalities were present.

No change was found in conjunctival oedema, conjunctival injection, ophthalmoplegia, pupils, lens, fundus, and refractive error.

The main toxic effect of this treatment was the development of a superficial punctate keratitis, which occurred in 10 patients.

The therapeutic value of local guanethidine in these eye conditions was confirmed. A number of precautions are suggested for long-term maintenance therapy in the light of the toxic effects found.

We thank Dr. A. K. Pitman, of Ciba Ltd., for generous supplies of guanethidine and also Professor J. A. Strong for his helpful advice and criticism during the period of study of patients under his care and also in the preparation of this paper. We are grateful also to Mr. A. McDonald for the preparation of the illustrations.

Preliminary Communications

Management of the Source of Pulmonary Emboli: the Value of Phlebography

[WITH SPECIAL PLATE FACING PAGE 573]

Brit. med. J., 1967, 4, 596-597

The conventional method of treating a patient who has survived a pulmonary embolus is to use anticoagulants and hope that no further emboli occur (Crane, 1957; Coon *et al.*, 1958; Barritt and Jordan, 1960). If there are further emboli most authors advocate some form of surgical blockade of the inferior vena cava (Moretz *et al.*, 1959; Spencer *et al.*, 1962; De Weese and Hunter, 1963; Miles, 1966; Lowicki, 1966). However, this type of operation has an appreciable morbidity, and if it is performed without showing either the presence or site of the peripheral thrombi it is as irrational as the blind administration of anticoagulants.

Barker and Priestley (1942), reviewing 1,665 cases of post-operative venous thrombosis, thrombophlebitis, and pulmonary embolism, found that 30% of patients who survived a pulmonary embolus had a second embolus and this was fatal in 19%. Thus after a patient has had a pulmonary embolus active treatment is urgently indicated to prevent a recurrence.

This preliminary communication describes the approach that we have developed to give patients the maximum protection from a second embolus with minimum morbidity.

METHODS

ASCENDING PHEBOGRAPHY OF THE LEGS

The patient lies on a tilting-table, the foot of the table being tilted 20 degrees downwards. A rubber tourniquet (Setoniquet, Seton Products Ltd., Oldham, Lancs.) is placed just above the ankle to distend the superficial veins of the foot. A vein on the dorsum of the foot, preferably towards the lateral side, is selected, and a small Middlesex cannula is inserted into the vein, with the use of local anaesthesia, in a distal (upstream) direction. If percutaneous puncture is not possible, a small cut-down is made.

The cannula is connected with polyethylene tubing to a 50-ml. syringe containing 40 ml. of the contrast medium Conray 280 (meglumine iothalamate) May & Baker Ltd. The foot is internally rotated to separate (radiologically) the tibia and fibula. The contrast medium is injected under television control and the tension of the tourniquet adjusted so that deep venous filling occurs. In order to fill all the calf veins it may be necessary to instruct the patient to plantar flex the foot a few times.

Split 14 by 14-in. (35.5 by 35.5-cm.) films are taken under television control during injection of the contrast medium. Films are taken of the whole venous system from the calf to the pelvis. The upper portion of the profunda vein is shown by asking the patient to perform a Valsalva manoeuvre when the common femoral vein is seen to be full of contrast medium. This technique usually shows the deep venous system from the ankle to the external iliac veins or even as high as the inferior vena cava, but if the femoral and iliac veins are not visualized percutaneous femoral vein injections are performed.

Both legs must always be examined.

If thrombosis of the iliac veins is suspected either on ascending phlebography or on clinical grounds and percutaneous

femoral puncture has not succeeded, it may be necessary to perform bilateral simultaneous peritrochanteric intraosseous pelvic phlebograms (Cockett and Lea Thomas, 1965).

After the films have been examined and regarded as satisfactory, at least 100 ml. of normal saline is injected into each leg and the legs are exercised to clear the contrast medium from the veins. This is checked by television. If the patient is not on anticoagulants 2,500 units of heparin are injected into each cannula before removal.

SURGICAL TECHNIQUES

Superficial femoral vein ligation is performed under either local or general anaesthesia. A vertical incision allows a greater length of vein to be exposed, which is of value if thrombectomy is planned.

Thrombectomy.—Thrombi are removed from the femoral and iliac veins through a venotomy in the common femoral vein by means of Fogarty venous thrombectomy catheters, suction, and a variety of forceps.

Plication of the inferior vena cava is usually performed through a right oblique flank incision, by the same retroperitoneal approach as for lumbar sympathectomy. Three or four interrupted sutures of 0000 arterial silk are passed through both walls of a flattened segment of the cava, approximately 2 mm. apart, to convert the vena cava into four or five channels (Spencer *et al.*, 1962).

ILLUSTRATIVE CASES

Seventeen cases of pulmonary embolus seen in the past year have been carefully studied by phlebography, and their management has been based on the radiological findings. The most striking feature was that the site of the thrombus, as demonstrated radiologically, often bore no relation to the site suspected clinically. Though the signs, when present, are usually associated with underlying thrombus, extensive thrombus may be demonstrated elsewhere—in the femoral or iliac veins of a leg with a tender calf or in a leg with no physical signs.

We concluded that the prevention of further emboli by surgical or medical means other than caval blockade could not be achieved without phlebography. The following three cases and their phlebograms demonstrate this point.

Case 1.—A 52-year-old woman had a simple mastectomy for carcinoma of the breast. Four days later she developed dyspnoea, pain in the chest, and haemoptysis. Anticoagulants did not prevent two further emboli. The right calf was tender and phlebography showed a small thrombus in the right common femoral vein. *The left leg was clinically normal.* Fig. 1 (Special Plate) shows that this leg contained an extensive, loose, potentially lethal thrombus. Thrombectomy and ligation of both superficial veins was performed.

Case 2.—This patient, a 32-year-old woman, developed chest pain, dyspnoea, and haemoptysis after two weeks of bed rest for low back pain. The left leg was swollen, painful, and blue. The clinical signs indicated a thrombosis of the iliofemoral segment. Peritrochanteric phlebograms (Special Plate, Fig. 2) showed an occluded iliac vein with fresh thrombus jutting into the vena cava. The cava was plicated.

Case 3.—A 45-year-old man had repeated pulmonary emboli after a femoral endarterectomy. The inferior vena cava was plicated without previous phlebography. He had a further embolus six months later. The phlebogram (Special Plate, Fig. 3) showed a double vena cava, not visible at operation—an unguarded route which could have been blocked at the first operation if its presence had been known.

PHLEBOGRAPHY

Technique.—The technique described for ascending phlebography is a modification of techniques used by many previous authors. It is simple and can be used in the very ill patient. Retrograde (upstream) injection into a lateral foot vein, foot-down tilting, the rubber tourniquet with the Velcro fastening, and the use of television are all important.

Interpretation of Results.—De Weese and Rogoff (1963) described the unequivocal diagnosis of deep vein thrombosis to be based on (1) the presence of well-defined filling defects in opacified veins, and (2) the demonstration of these defects on at least two radiographs. Recent thrombus appears as a rounded or cylindrical filling defect in a contrast-filled vein giving it a "ground-glass" appearance (Special Plate, Fig. 1). The thrombus is separated from the wall of the vein by a thin white line representing contrast medium around the thrombus. Old thrombus shows as filling defects projecting directly from the walls of the veins. The intramuscular calf veins and soleal sinusoids are difficult to fill by ascending phlebography (Cotton and Clark, 1965). Failure to fill these veins cannot be taken as evidence of occlusion, and in the absence of positive evidence of thrombus within these veins non-filling should be assumed to be a technical fault. Conversely, non-filling of the popliteal, femoral, and iliac veins has been taken as evidence of total occlusion, provided contrast medium enters the deep venous system of the calf. The internal iliac veins cannot be demonstrated by ascending phlebography and if these veins are suspected as the source of a pulmonary embolus intraosseous petrochanteric phlebography is necessary. False-positive diagnoses have not proved a problem.

TREATMENT

By defining the site and extent of the residual thrombus we have been able to apply the various methods of treatment available in a logical manner. The policy has been to "lock-in" the thrombus as low as possible.

Of our last 17 patients, five had a plication of the inferior vena cava (two of whom should have been treated by thrombectomy and superficial femoral vein ligation, on the basis of our final policy), one had plication of both external iliac veins, two had one common femoral vein and one superficial femoral vein tied, and two had their superficial femoral veins ligated. These procedures were combined with thrombectomy in six patients, in three of whom a large potentially lethal thrombus was removed.

Seven patients were treated with anticoagulants alone, though surgical treatment, particularly thrombectomy, would have been indicated in some of these if they had been seen earlier. Thus in our experience surgical blockade of the inferior vena cava which is currently so popular is necessary in only a small proportion of patients, the remainder can be treated by a more peripheral blockade.

We suggest that the management of all patients who have had a pulmonary embolus that does not require immediate embolectomy should be as follows:

- (1) Anticoagulate with heparin.
- (2) Perform emergency bilateral ascending phlebography.

(3) If no thrombus is seen in the leg veins, and the iliac veins have not been visualized, perform a pelvic phlebogram via a percutaneous femoral vein puncture or interosseous petrochanteric injection.

(4) Surgical treatment depends on the phlebograms. (a) For thrombus confined to the calf or popliteal vein, superficial femoral vein ligation only. (b) For thrombus extending into the femoral and external iliac veins, thrombectomy and superficial femoral vein ligation. If in such cases the profunda vein has not been displayed on the phlebogram it should be explored with a Fogarty catheter. If no thrombus is found, superficial femoral vein ligation is safe. If thrombus is present then the common femoral vein must be ligated or plicated. (c) For recent thrombus confined to the iliofemoral region above the junction of superficial and profunda veins, thrombectomy alone. (d) For irremovable thrombus above the formation of the common femoral vein, plication of the common iliac veins or inferior vena cava.

(5) Anticoagulants alone are indicated if the phlebogram shows a small amount of apparently old thrombus confined to the calf or popliteal veins or if no thrombus is seen and the diagnosis of pulmonary embolus is certain.

We continue the anticoagulants for six months to prevent the formation of fresh thrombus in the period when the residual thrombus is contracting, the vessel being recanalized, and new endothelium being formed.

No recurrent emboli have occurred since we adopted this regimen and we hope to present a long-term follow-up of these and other patients in a year's time.

SUMMARY

A rational approach to the prevention of a second pulmonary embolism following the first, based on bilateral leg phlebography, is described. The long-term clinical value of these suggestions is under trial.

Medical Memoranda

Case of Late Pulmonary Embolectomy

[WITH SPECIAL PLATE FACING PAGE 573]

Brit. med. J., 1967, 4, 598-599

The recent reawakened interest in pulmonary embolectomy has chiefly directed attention to operation as a definitive, unhurried procedure, in contrast to the more tempestuous "rush and grab" of the original Trendelenburg operation. The reason for reporting this case is fourfold: (1) it illustrates the importance of diagnosis; (2) it shows that if one pulmonary artery is affected a quite simple operation suffices; (3) it shows that late operation can be successful, indeed may be obligatory; and (4) that an embolus which does not cause early death may not be removed by lysis but can remain to cause permanent harm.

CASE REPORT

A man aged 50 had a low backache for five months, followed by pain down the outside of the left leg and foot which was said to be due to prolapse of a vertebral disc. He received various treatments, including a corset.

Three weeks after this and 17 weeks before being referred for his lung condition he had pain, swelling, redness, and pitting oedema of the left leg lasting 10 days. During this time he was mobile. Three weeks later—that is, 14 weeks before being referred—he suffered the sudden onset of pain in the left side of the chest, worse on breathing and moving. Dyspnoea became severe and oxygen was needed. He also coughed up a little blood. Over the next three weeks his breathing improved and he was then comparatively well for two months.

One month before referral he had a sudden onset of dyspnoea and palpitations while in the toilet. Two weeks later he was sitting reading when he had a sudden onset of severe left-sided chest pain with palpitations, dyspnoea, coldness, and sweating. He also coughed up some blood.

He was admitted to hospital with a diagnosis of "pleurisy" and was treated with antibiotics. The pleuritic pain improved but dyspnoea remained.

On 20 December he was seen by one of us (H.N.) for the first time, and a diagnosis of pulmonary embolism was made from the story and the radiological appearance of a poor vascular pattern in the left lung. This suggested embolism of the left pulmonary artery; an angiogram taken by Dr. Chafizadeh and Dr. Massin, of Teheran, confirmed this (Special Plate, Fig. 1).

The plain radiographs of November 1966 showed evidence of bilateral pulmonary embolism. The radiographs of 26 December showed improvement in the patchy opacities previously in the right lung.

The angiogram of 29 December showed an apparent dilatation of the pulmonary trunk and of its branches. The left pulmonary artery had a gross filling defect with no evidence of contrast medium entering the left upper lobe and very little in the left lower lobe. The appearances on the right side suggested partial occlusion of some branches of the upper lobe and poor and late filling of branches of the lower lobe and perhaps the middle lobe. It appeared as if several smaller emboli had lodged in smaller branches of the right pulmonary artery.

The patient was flown to London and admitted to the Brompton Hospital on 7 January 1967. He presented the clinical features of moderate pulmonary hypertension with normal jugular venous pressure. The pulse was regular; blood pressure was 90/60 mm Hg. The E.C.G. showed P-pulmonale and QS in lead III that might

indicate an old posterior myocardial infarct. A quiet systolic murmur could be heard over the right upper lobe.

It seemed certain that the greater part of the left lung was deprived of its arterial blood flow by an old embolus. The patchy lesions on the right side did not look suitable for operation, and so it was decided to deal with the left pulmonary artery as a definitive procedure without the use of heart-lung bypass.

OPERATION

Thrombo-embolectomy of left pulmonary artery was done on 16 January, anaesthesia being conducted by Dr. Ruth Mansfield. Left posterolateral thoracotomy was made through the bed of the fifth rib. The upper lobe was densely adherent over the anterior segment and slightly adherent around this. The very adherent area corresponded with a pyramidal infarct about 4 cm. across in the anterior segment.

The left pulmonary artery was dissected from its origin down into the interlobar fissure. The appearance corresponded with that seen on angiocardiology. The first part of the artery was patent and the block was sudden and complete with extensions of thrombus or thromboembolism into the upper lobe branches.

The artery was clamped proximally and controlled distally by a rubber loop. It was opened by a longitudinal incision from above the highest upper lobe branch to the level of the apical lower branch. The obstruction consisted of old firm clot with a little recent thrombus. The extensions into the upper lobe branches were teased out with the aid of a small curette. The apical lower branch was similarly cleared and also the basal branches so far as was possible. The more distal branches still felt solid and it was not possible to secure any more thrombus by "milking" the lobe. After removal of clot the intima looked smooth and healthy; a weak heparin solution was injected into the distal branches. Previously a systemic dose of 1 mg./kg. had been given.

Sufficient back bleeding occurred from distal branches to indicate that total thrombosis had not occurred. It was presumed that distal patency had been ensured by the bronchopulmonary anastomosis.

The incision in the artery was closed, and when the clamp and snares were released very satisfactory and encouraging pulsation was present in the artery and in its branches.

Inspection of the thrombus showed almost uniform old adherent yellow clot in which it was not possible to identify any coiled embolus. Some of the portions extracted from the branches were redder and conical. Through an oversight pressures were not taken in the pulmonary arterial system.

Recovery from the operation was uneventful, and the chest radiograph showed greatly improved lung vascularity. Both objectively and subjectively he lost his dyspnoea.

An angiogram taken 14 days after operation by Dr. G. H. Miller showed a striking restoration of the arterial pattern of the left lung (Special Plate, Fig. 2), in great contrast to the preoperative state.

The improvement and well-being continued up to the time of writing. He had no signs of pulmonary hypertension.

COMMENT

This case shows several important features as were outlined in the introductory remarks. The long overlooked diagnosis was confirmed by angiocardiology. In spite of the four months that had elapsed since embolism it was still possible to perform completely successful thromboendarterectomy. The process had not caused occlusion of the distal arterial branches; these had presumably been kept patent by the minor inflow of blood from bronchopulmonary anastomotic vessels.

It is doubtless true that if death does not occur from pulmonary embolism, clots may be removed by a process of lysis and the patency of the vessels may be restored. This case shows that this cannot be relied on to happen, and if severe secondary pulmonary hypertension is to be avoided with its attendant dyspnoea and disability, removal of embolus and clot may be necessary. Presumably whether a particular embolus may be dissolved by lysis or not will depend on its

age. A recent soft embolus is more likely to be lysed than an older, rigid, and possibly partly organized one.

Hypoglycaemic Coma Occurring during Treatment with Chlorpromazine and Orphenadrine

Brit. med. J., 1967, 4, 599-600

Hypoglycaemia may occur with several drugs in addition to those used in the treatment of diabetes. This report describes the findings in a patient presenting in hypoglycaemic coma during treatment with chlorpromazine and orphenadrine. No such association appears to have been reported previously.

CASE REPORT

A 53-year-old married woman was admitted to hospital in coma. For some years she had been under psychiatric care, and during the previous two months had been treated with chlorpromazine 100 mg. four times a day, together with trifluoperazine (Stelazine). One week before her admission the latter drug was replaced by orphenadrine (Disipal) 50 mg. three times a day. Three days later she began to have "attacks" of excessive sweating with dryness and paraesthesiae of the mouth and tongue. On the night of admission, though feeling normal on retiring to bed, she was found later to be groaning and unrousable. She was receiving no other drugs, was only a moderate smoker, and drank no alcohol.

On examination she was sweating profusely and was deeply comatose. Slow roving movements of the eyes were observed, but the pupils responded to light. There was no papilloedema or neck stiffness and Kernig's sign was negative. Both sides of the body moved slightly in response to painful stimuli; the tone of the limbs was reduced, but the tendon reflexes were all present. The plantar responses were extensor. The pulse rate was 76 and regular; the blood pressure was 150/90. Otherwise the examination showed nothing abnormal.

A clinical diagnosis of hypoglycaemic coma was made by the house-officer on duty (J. G.). The patient was given 20 ml. of glucose (25% w/v) intravenously, after which she quickly recovered consciousness. The blood sugar before treatment was 30 mg./100 ml. (potassium ferricyanide method, normal fasting level 65-100 mg./100 ml.), and after intravenous glucose was 57 mg./100 ml.

Chlorpromazine and orphenadrine treatment was continued, and the following night she had another hypoglycaemic coma, during which the blood sugar fell to 44 mg./100 ml. Recovery was rapid after 20 ml. of glucose (50% w/v) intravenously.

Investigations.—The peripheral blood count, erythrocyte sedimentation rate, urinalysis, and x-ray films of the chest and skull showed no abnormality. All tests of liver function were normal. The serum protein-bound iodine was 4.8 μ g./100 ml. The 24-hour urinary excretion of 17-ketosteroids was 10.3 (7.2) mg., of 17-ketogenic steroids 3.2 (8.2) mg., and of 17-hydroxycorticosteroids 5.9 (11.2) mg. (The values in parentheses are repeat estimations while the patient was receiving orphenadrine alone.)

CARBOHYDRATE HOMOEOSTASIS

Investigations were carried out during and after stopping treatment with the two drugs.

(a) *During Treatment with Chlorpromazine and Orphenadrine.*—The fasting blood sugar was 55-65 mg./100 ml., and the patient

had a further episode of hypoglycaemic coma (see above) at this time. After tolbutamide (1 g. intravenously) the blood glucose (glucose oxidase method) fell from 65 to 29 mg. at 45 minutes, and slowly rose to 34 and 38 mg./100 ml. at two and three hours respectively (Fig. 1). The fasting level of plasma insulin (measured by radioimmunoassay) was 9 μ U/ml. During the tolbutamide test the plasma levels of insulin were 14 μ U at 30 min., 17 μ U at 45 min., 11 μ U at 60 min., and 12 μ U at 90 min. (all levels being within normal limits). After oral glucose (50 g.) the blood glucose

FIG. 1.—Effects of tolbutamide (1 g.) given intravenously on blood glucose levels. FIG. 2.—Six-hour glucose-tolerance tests. (Glucose estimated by the glucose oxidase methods in both instances.)

rose to 162 mg. at one hour, fell to 52 mg. at three hours, and remained below 60 mg./100 ml. for the remainder of the six-hour test (Fig. 2). The patient was starved for 72 hours, during which time the blood glucose fell to 42-44 mg./100 ml., but no hypoglycaemic symptoms developed. The response to glucagon (1 mg. intramuscularly) was normal. The blood glucose rose by 35 mg./100 ml. during the first 30 minutes, and thereafter slowly fell to a minimum value of 50 mg./100 ml. at four hours.

(b) *During Treatment with Orphenadrine Alone.*—One week after stopping chlorpromazine the fasting blood sugar had risen to 77–88 mg./100 ml. After tolbutamide the blood glucose fell to 38 mg./100 ml. at 45 minutes, but reached two-thirds the fasting value at two and a half hours (Fig. 1). The six-hour glucose-tolerance curve showed a normal pattern (Fig. 2).

(c) *No Treatment.*—Repeat studies one week later showed a normal fasting blood sugar, while the tolbutamide test (Fig. 1) and the six-hour glucose-tolerance test (Fig. 2) were both normal. It was therefore not felt justified to subject the patient to a further 72 hours of starvation.

No hypoglycaemic episodes or other abnormalities have emerged during surveillance for the past 18 months, and fasting blood sugars have been normal.

COMMENT

The patient's symptoms and two comas occurred in the postabsorptive state, responded quickly to glucose, and ceased when treatment was stopped.

Studies of chlorpromazine on carbohydrate metabolism have yielded conflicting results. Some reports have shown hyperglycaemia and decreased glucose tolerance (Courvoisier *et al.*, 1953; Dobkin *et al.*, 1954; Charatan and Bartlett, 1955), while other studies have found no effect on blood sugar and an increased tolerance (Donegani *et al.*, 1959; Bonaccorsi *et al.*, 1964).

Orphenadrine is a substituted derivative of diphenhydramine. None of this group of antihistamines has any known effect on carbohydrate metabolism, though some of the ethylene diamine group (such as antazoline) may cause asymptomatic reduction of blood sugar when given in high dosage (Goldner and Jauregui, 1954).

After tolbutamide the absolute fall in blood glucose was greater, and the rate of return towards normal was slower during treatment with both chlorpromazine and orphenadrine than with the latter alone, normality being achieved only when both were stopped. The normal circulating insulin levels, both fasting and during tolbutamide-stimulation, suggest that the drugs did not stimulate its secretion; they also, along with the absence of further attacks of hypoglycaemia during the past 18 months, make it unlikely that the patient's symptoms were due to an insulinoma or to an undetected extrapancreatic tumour.

The therapy may have increased the effectiveness of action of normal quantities of secreted insulin. Another possibility is an increased tissue uptake of glucose due to a direct effect of the drugs, for orphenadrine inhibits aerobic metabolism (de Waart, 1958; Lewis and Van Petten, 1963).

There could have been an interference with humoral mechanisms normally maintaining the blood sugar. Chlorpromazine inhibits many of the peripheral actions of adrenaline, but is without effect on its hyperglycaemic action (Courvoisier *et al.*, 1953). Impairment of the secretion of glucagon could contribute to hypoglycaemia, especially during fasting. But the normal response to glucagon in this patient excluded any

significant impairment of glycogenolysis caused by interference with phosphorylase activity.

Growth hormone and A.C.T.H. play a part in maintaining the blood sugar, and both are under hypothalamic control (Reichlin, 1963). Chlorpromazine depresses the hypothalamus (Goodman and Gilman, 1965) and interferes with the release of several pituitary hormones (Christy *et al.*, 1957); it could thereby interfere with carbohydrate homeostasis. During the combined therapy the 24-hour excretion of 17-ketosteroids and 17-hydroxycorticosteroids was depressed, but after stopping chlorpromazine there was a rise in their excretion, suggesting an inhibitory effect of chlorpromazine on hypothalamic-pituitary mechanisms.

Investigation suggested that chlorpromazine had the greater hypoglycaemic effect. Yet carbohydrate homeostasis became normal only when orphenadrine was also stopped, and the patient had been symptom-free initially on chlorpromazine alone. This, with their structural similarity, suggests a summative effect between the two drugs. Both share the group— $\text{CH}_2\text{—CH}_2\text{—N—}$ —with the ethylene diamines, but this alone is unlikely to be responsible. It is possible that summation of a direct peripheral effect of orphenadrine together with the central hypothalamic-pituitary effect of chlorpromazine may be sufficient to cause manifest hypoglycaemia.

Chlorpromazine and orphenadrine individually are commonly prescribed, but when used together the possibility of hypoglycaemia should be considered.

Our thanks are due to Dr. K. O. Black, under whose care this patient was admitted, for allowing us to publish details of the case. We also wish to thank Dr. K. W. Taylor for kindly performing the insulin radioimmunoassay determinations, and Dr. A. B. Anderson for the glucose oxidase determinations.

Case of Cronkhite-Canada Syndrome with Associated Jejunal Diverticulosis

Brit. med. J., 1967, 4, 601-602

The association of gastrointestinal polypi with diffuse alopecia and nail dystrophy was first recorded by Cronkhite and Canada (1955). This paper records the ninth patient with this syndrome.

CASE REPORT

The patient was a schoolmaster aged 60. In 1957 diffuse alopecia and "unusual nails" were noted during investigations for dyspepsia. Laparotomy revealed a nodular pancreas, and chronic pancreatitis

these were polypi was confirmed by gastroscopy and gastric biopsy. The investigations indicated the presence of hypomagnesaemia, hypocalcaemia, and hypokalaemia, presumably secondary to jejunal diverticulosis. At this time there was no conclusive evidence of more generalized intestinal malabsorption. Oral replacement therapy with magnesium hydroxide, vitamin D, calcium gluconate, and potassium citrate produced an improvement in his general condition, but between 1963 and 1966 he complained of intermittent upper abdominal discomfort, vomiting, and anorexia. His weight fluctuated considerably and on two occasions he was admitted to hospital for blood transfusion because of occult gastrointestinal bleeding. A string test suggested bleeding from the jejunum.

Investigations of intestinal function in 1967 revealed more generalized malabsorption (see Table). The presence of excess urinary indican, together with an excellent response to antibiotic therapy (ampicillin 250 mg. q.i.d.), suggested that a change in bacterial flora may have been responsible for the enteropathy.

Finger-nails showing gross changes.

was suspected. The following year a gastroenterostomy was performed, but at neither operation was any abnormality of stomach or small bowel reported. In 1962 an epileptic fit necessitated a further hospital admission. His general health was good, though paraesthesiae in the hands had been noted for two weeks. His bowel actions were normal.

On examination no abnormal pigmentation of the skin or mucous membranes was seen. He had diffuse non-scarring alopecia and the body hair was also scanty. All finger-nails and toe-nails, except for the right fourth and fifth toes, were strikingly abnormal (see Fig.). In the proximal half the normal nail was replaced by a triangular area consisting of a thin nail-plate, fleshy in colour; it felt soft and could easily be indented. This abnormal nail was continuous distally with a hard thick nail which was ridged longitudinally in the midline and obliquely to each side. This part of the nail was brown in colour and was darkest and thickest centrally. Chvostek's sign and Trousseau's sign were negative, but there was a general increase in muscle tone, with spontaneous fasciculation over the quadriceps and bilateral ankle clonus.

Investigations at this time are shown in the Table. In addition, a glucose-tolerance test and Schilling test were normal. Barium enema showed nothing abnormal. Barium-meal examination showed multiple large jejunal diverticula and multiple round filling defects on the stomach wall and to a less extent in the duodenum. That

Faecal excretion of an intravenous injection of povidone-iodine (^{131}I polyvinylpyrrolidone) was at the upper limits of normal.

His general health is better and the alopecia is a little less diffuse, but his nails, though improved, remain abnormal.

COMMENT

The association of gastrointestinal polypi, alopecia, and nail dystrophy was first reported by Cronkhite and Canada (1955). Since then eight other cases have been reported. Of the nine unrelated patients, whose ages ranged from 51 to 75 years, three were males.

In our patient the appearance of the nails was distinctive and could be explained by the formation of ventral nail in the absence of normal nail production by the matrix. This has been noticed in one other patient with the Cronkhite-Canada syndrome (Shuster, personal communication) and may be a feature of it. The nail dystrophy is not pathognomonic, as it has been reported in a patient with pustular psoriasis (Samman, 1961). Alopecia and generalized pigmentation were present in all previously reported cases, but though similar diffuse hair changes had occurred in the above patient increased pigmentation was absent.

The relation between disorders of the skin and gut have recently been classified by Shuster (1967) into four groups. One cannot yet classify the Cronkhite-Canada syndrome under any of these groups, since it is not known whether the ectodermal changes are dependent on or associated with the endodermal changes.

Though our patient had only gastroduodenal involvement, polypi may involve any site of the gastrointestinal tract. A striking feature of most cases has been the severity of the symptoms and signs, which seem to be related to the extent of the polypi. Eight of the cases had diarrhoea and the faecal fat was unequivocally increased in three of the four cases in which

Summary of Investigations

Investigations	1962	1967
Haemoglobin (g./100 ml.)	13.3	14.0
Serum iron ($\mu\text{g.}/100\text{ ml.}$)	15	245
Iron-binding capacity ($\mu\text{g.}/100\text{ ml.}$)	186	330
Serum vitamin B ₁₂ ($\mu\text{g.}/\text{ml.}$)	395	357
Serum folic acid (m $\mu\text{g.}/\text{ml.}$)	3.0	—
Serum potassium (mEq/l.)	2.7	4.7
Serum calcium (mg./100 ml.)	8.0	9.3
Serum magnesium (mg./100 ml.)	0.3 and 0.6	2.4 and 2.3
Plasma inorganic phosphate (mg./100 ml.)	2.5	2.9
Serum proteins (g./100 ml.)	6.8	6.1
Electrophoresis	Normal	Normal
Urinary magnesium* (mg./24 hours)	3.2 and 2.4	—
5 day faecal fat excretion† (g./day)	5	14
Xylose excretion test‡ (g. in 5 hours)	6.5	2.7

* Normal 70-120 mg./24 hours. † As stearic acid. ‡ After 25 g. xylose by mouth.

the estimation was performed. Jarnum and Jensen (1966) demonstrated protein-losing enteropathy in their patient.

Five of the reported cases have had a fatal outcome (Cronkhite and Canada, 1955; Martini and Dölle, 1961; Johnston, Vosburgh, Wiens, and Walsh, 1962; Jarnum and Jensen, 1966), usually within 18 months of the onset of the diarrhoea. Spontaneous clinical and biochemical remissions occurred in one patient (Kennedy and Hirson, 1961). Two were improved by removal of the polypi—one by a gastrectomy (Manousus and Webster, 1966) and the other by a hemicolectomy (Zdansky and Riederer, 1963).

Jejunal diverticulosis and pancreatic disease have not been previously reported in this condition and it is possible that these may be part of the syndrome.

Jejunal diverticulosis is a well-recognized cause of intestinal malabsorption. Booth, Babouris, Hanna, and MacIntyre (1963) drew attention to the not uncommon finding of hypomagnesaemia, which was present in 15 out of 42 cases of intestinal malabsorption of various causes reported in their series. An interesting feature in the present case is the presentation with paraesthesiae and convulsions due to hypocalcaemia and hypomagnesaemia, and the later development of more generalized malabsorption despite symptomatic improvement and weight

gain after treatment with oral supplements and broad-spectrum antibiotics.

We wish to thank Professor G. Smart, under whose care the patient was admitted, and Professor Sam Shuster for their advice and constructive criticism.

W. J. CUNLIFFE, M.B., B.Sc., M.R.C.P.,
Registrar in Dermatology.

Haemoperitoneum Associated with a Ruptured Gall Bladder

Brit. med. J., 1967, **4**, 602

Leared (1859) was the first to recognize that the gall bladder could be the source of catastrophic intra-abdominal haemorrhage. He described finding a ruptured gall bladder and 2 quarts (2.3 litres) of blood in the abdominal cavity of a man of 22 at a post-mortem examination. Since then the condition has been reported infrequently. Raycroft and Mastrangelo (1960) were able to collect only 18 cases from the world literature.

CASE REPORT

A man of 55 was admitted to hospital on 26 January 1966. His admission was precipitated by 48 hours of severe generalized abdominal pain accompanied by abdominal distension and constipation. He gave a long history of dyspepsia—30 years previously he had had a haematemesis and since then had been subject to periodic bouts of epigastric pain relieved by food. During the year before admission he had had attacks of pain in the right lower chest and for two months had also had central abdominal colicky pains and increasing distension. A barium-meal examination shortly before admission had failed to show a cause for his dyspepsia, and six days before his admission his haemoglobin was 106%.

Examination showed an obviously ill man. He was pale and clammy and had a pulse rate of 120. The abdomen was distended and though tender all over it was particularly so in the right hypochondrium. Tenderness was also elicited on rectal examination. On auscultation bowel sounds were present. Radiographs of the abdomen showed gaseous distension of both the small and large bowel. The serum amylase was 89 Somogyi units and the haemoglobin 66%.

After preliminary intravenous fluid replacement a laparotomy was performed. One and a half litres of blood and blood clot were found in the abdomen. This clearly arose from the gall bladder, which had a 2-cm. tear across Hartmann's pouch. The cystic artery was severed and blood was continuing to spurt from the proximal end. The gall bladder contained blood clot, but both it and the common bile duct appeared to be normal otherwise. No evidence of peptic ulceration was found. Cholecystectomy was performed

and the blood was removed from the abdominal cavity. Histological examination of the gall bladder showed evidence of chronic cholecystitis. The patient's postoperative progress was entirely uneventful.

COMMENT

Severe bleeding from the biliary tract is uncommon. During recent years, however, it has been shown that in a small proportion of patients with gastrointestinal haemorrhage the biliary tract is the source of the bleeding. The diagnosis has usually been made only after repeated haemorrhages have occurred and after previous gastric surgery has been undertaken (Fitzpatrick, 1961). Haemobilia has been recorded from very varied pathological causes. Minor bleeding is not uncommon in calculous cholecystitis, especially when accompanied by stones in the common bile duct, but cholecystitis appears to be the least common cause of severe bleeding. Mailer (1939), commenting on a fatal case of spontaneous rupture of the gall bladder with intraperitoneal haemorrhage, stressed the lack of inflammation in the gall bladder. Though the gall bladder in the present case showed histological evidence of chronic cholecystitis it was not the site of acute inflammation or of ischaemic necrosis. It is therefore by no means clear why the gall bladder should have ruptured, but it does seem likely that the cause was essentially a mechanical one. If the bleeding was caused by rupture of the gall bladder, the cause of the rupture remains unexplained. It is therefore thought more likely that bleeding occurred into the gall bladder first. Blood clot may have obstructed the neck of the gall bladder, leading to a rise of tension sufficient to bring about its rupture.

I am grateful to Mr. I. W. Matheson for permission to publish this case.

Current Practice

MEDICINE IN THE TROPICS

Malnutrition in Childhood in the Tropics

C. GOPALAN,* M.D., PH.D.

Of the many causes of ill-health among children of the tropics malnutrition is undoubtedly the most important. Apart from its direct effects on health, malnutrition also exerts an indirect effect by diminishing resistance to infectious diseases.

The infant and child mortality rates in tropical countries are high. In India, according to the latest census figures, while infants and children under the age of 5 years constitute 16.5% of the total population, deaths within this age group account for 40% of the total deaths in the country. Infant and toddler mortality rates in some of the tropical countries are shown in Table I. A curious reflection of such high mortality in infancy and childhood is that in contrast with the situation in Europe the average expectation of life in tropical countries is actually higher at the age of 5 years than at birth. These data indicate the magnitude of ill-health among infants and children in tropical countries.

TABLE I.—Infant and Toddler Mortality Rates in Different Countries

Developed Countries	I.M.R.	T.M.R.	Developing Countries	I.M.R.	T.M.R.
Australia	19.1	1.0	Columbia	90.0	15.6
Belgium	25.8	1.0	El Salvador	65.5	22.7
Canada	24.7	1.1	Guatemala	91.6	42.7
France	23.4	1.2	Guinea	42.0	55.4
Japan	20.4	1.9	Mexico	66.3	14.7
Netherlands	14.8	1.1	Costa Rica	86.4	N.A.
Sweden	14.2	0.8	Honduras	50.0	13.5
U.S.A.	24.8	1.0	Venezuela	48.0	5.5
			India	81.0	12.0
			Malaya	57.0	34.0
			Philippines	67.4	8.1

I.M.R. = Infant Mortality Rate per 1,000 live births.
T.M.R. = Toddler Mortality Rate per 1,000 population.

Among poor communities in the tropics undernutrition and an unhygienic environment are inseparable factors, which tend to interplay with and aggravate each other. It is therefore difficult to decide how far these mortality figures are attributable to malnutrition and how far they are the result of insanitary and unfavourable environment. However, a careful scrutiny of the data offers some suggestive indications.

A considerable proportion of infant deaths in the tropics occurs in the neonatal period. Analysis reveals that nearly 75% of these deaths are directly attributable to "premature birth." A study of over 16,000 obstetric cases in Madras in South India¹ showed that the incidence of premature births (using the criterion of body weight of 5 lb. (2.2 kg.) as normal) was 8.1% among the poor general-ward patients as against 1.6% among the well-to-do patients admitted to the special wards. Using the international criterion of a birth weight of 5½ lb. (2.5 kg.) in full-term infants as evidence of prematurity, Varkki *et al.*² found that the incidence of prematurity among infants in Coonoor (South India) was three times as high in poor communities as in the well-to-do group. Such a high incidence of prematurity may be considered as a reflection of maternal malnutrition.

* Director, Nutrition Research Laboratories, India.

The extreme severity of the malnutrition in pregnant mothers in the poorest sections of populations in the tropics can be gauged from the results of recent surveys. In a study of the diet of pregnant women of the low socio-economic groups in South India the average daily intake of protein was 44 g. (animal protein 6 g.), of calcium 300 mg., and of iron 18 mg. The total calorie intake was 1,575.

Nutrition in Early Infancy

If the infant in the tropics manages to survive the hazards of the neonatal period he is relatively safe till the end of the first year in spite of his insanitary environment. During at least the first six months the infant receives, through his mother's milk, the nutrients which he needs in amounts which are probably not too inadequate. It is gratifying that women of the low socio-economic group in the tropics are able to breast-feed their infants successfully for prolonged periods. Instances of inability to breast-feed infants, which are frequent among the sophisticated high socio-economic groups, are extremely rare among the poor. This is surprising in the light of the diet of the nursing mothers, which provides less than 50 g. of protein daily, mainly derived from vegetable sources.

In a study among poor South Indian women it was observed³ that the daily output of breast milk varied from about 600 ml. within the first six months of lactation to about 350 ml. between the 18th and 24th months. The composition of the breast milk obtained at different stages of lactation showed that the milk was quite satisfactory with regard to the proximate principles, though not with regard to vitamins and minerals (Table II). These observations point to the need for encouraging breast-feeding by poor communities in the tropics, though it must be borne in mind that these underfed mothers are able to maintain satisfactory lactation only at the expense of their own tissues.

TABLE II.—Composition of Human Milk

Duration of Lactation	Protein g./100 ml.	Fat g./100 ml.	Lactose g./100 ml.	Vitamin A i.u./100 ml.	Vitamin B µg./100 ml.	Vitamin B ₁₂ µg./100 ml.	Vitamin C mg./100 ml.	Calcium mg./100 ml.	Phosphorus mg./100 ml.
1-6 months	1.06	3.34	7.47	79	15.3	19.0	1.9	36.3	11.7
7-12 months	1.01	3.23	7.54	66	14.5	18.1	2.5	34.1	12.0
13-18 months	1.05	3.79	7.54	65	16.5	17.2	3.2	29.8	12.6
More than 18 months	1.13	3.41	7.51	66	15.1	11.5	2.9	36.6	11.1

Growth and Development

At least for four months after birth the growth rates of Asian infants are not significantly lower than those of infants of the technically developed regions of the world. While this is true of growth rates, the actual weights of Asian infants even

within the first six months of birth are lower than those of normal infants elsewhere. In Fig. 1 the heights and weights of infants and children belonging to the poor socio-economic groups in India have been compared with those of American infants and children of corresponding ages. Among European and American infants chest circumference has been reported normally to overtake head circumference around the first year. In Asian infants of the poor socio-economic groups, however, this has been found to take place at about the third year. It is, however, interesting that no significant retardation has been observed with regard to the attainment of milestones of development in infants of the tropics.

It is the universal practice among poor communities in the tropics that infants are breast-fed for prolonged periods, often extending to two years. It is also the usual practice in many poor communities that infants are maintained solely on breast milk till the end of the first year. Supplementary foods are invariably unmodified versions of the adult diets and are almost solely cereal-based. Milk and animal protein foods figure only occasionally. Due to ignorance and prejudices green leafy vegetables and fruits are also not often included. Even such qualitatively deficient diets are often fed in quantities which are inadequate. The general impression that infants and children in the tropics are "overstuffed" with starchy foods providing adequate or more than adequate calories is not borne out by actual surveys. In view of the remarkable growth retardation the protein intake on the basis of actual body weights may appear to be only marginally deficient. However, in view of the inadequacy of calories in the diets a considerable proportion of the protein must be utilized for energy purposes. The intake of vitamins, especially of vitamin A, either preformed

or as carotene, is also low; the intake of calcium rarely exceeds 400 to 500 mg.

An elaborate account of the classical nutritional deficiency diseases affecting children will not be attempted here. Excellent descriptions of such classical syndromes as scurvy, rickets, and infantile beriberi, are available in standard textbooks. In this paper major nutritional problems affecting children of the tropics will be briefly discussed.

Protein-Calorie Malnutrition

Among the various types of malnutrition in children of the tropics protein-calorie malnutrition is the most widespread and important. Two major clinical forms have been recognized, kwashiorkor and marasmus.

Kwashiorkor

Kwashiorkor is generally seen in children between 1 and 3 years of age. The onset of the disease is insidious. Towards the latter half of the first year the child shows failure to grow and a lack of interest in the surroundings. He has frequent attacks of diarrhoea and other infections. There is often loss of appetite and increasing apathy, and the child may develop discoloration of the hair and skin and a characteristic fullness of the face. Later the ankles swell, and oedema gradually spreads upwards. It is at this stage that the child is generally brought to the hospital (Figs. 2 and 3).

Growth failure and hypoproteinaemic oedema are accepted as minimal diagnostic criteria for the disease. Oedema is maximal in the dependent parts, but ascites is uncommon. There is generally no albuminuria, and this differentiates the oedema from that of renal origin. The clinical severity of the oedema bears no relation to the ultimate prognosis or to the response of the case to treatment.

The hair can be plucked off easily and is often discoloured. The discoloration may not be present throughout the length of the hair, but only in segments, and this is termed the "flag

FIG. 1.—Comparison of height and weight of American and Indian children.

FIG. 2.—Child suffering from kwashiorkor showing oedema and skin

sign." The skin is scaly and shows characteristic changes which have been designated "crazy pavement dermatosis." The lesions start as black patches, especially over pressure points, which later exfoliate, exposing hypopigmented areas bordered by hyperpigmented zones.

Alimentary disturbances are the rule. There is marked anorexia, and diarrhoea is frequent. Pathogenic bacteria can be found in the stools in only a small percentage of the cases. However, in view of the high incidence of parasitic infestations in the tropics, ova of parasites, especially roundworm ova, are frequently seen. The faeces often show microscopic fat globules. The diarrhoea responds to high-protein therapy, and can therefore be regarded as a manifestation of protein deficiency.

The liver may or may not be enlarged. Liver biopsy invariably reveals extreme degrees of fatty infiltration, but contrary to previous belief this never leads to hepatic cirrhosis. General signs of associated vitamin deficiencies are usually present, commonly those of vitamin A and the vitamin-B complex.

There is a marked hypoproteinaemia, the reduction being greater in the albumin fraction. The serum protein and albumin levels are of the order of 4.5 and 1.9 g./100 ml. respectively. There is a reduction in many of the serum enzymes, the blood urea, and the blood cholesterol.

Anaemia is often present, and is mainly due to iron deficiency, but concomitant deficiency of other haematinic factors should also be borne in mind.

Marasmus

Marasmus is seen in a younger age group, usually between 6 and 12 months of age. These infants are usually exclusively breast-fed, and the milk available is not adequate for proper growth. There is therefore a gross calorie undernutrition. A typical case of marasmus is characterized by gross underweight, marked muscular wasting, and loss of subcutaneous fat.

TABLE III.—Differences Between Kwashiorkor and Marasmus

	Kwashiorkor	Marasmus
Age of incidence	12-36 months	6-18 months
Oedema	Invariably present	Absent
Muscle wasting	Mild to moderate	Severe
Loss of subcutaneous tissue	Mild	Marked
Hair	Discoloration; easy pluckability	Normal
Skin	Scaly; dyspigmentation; crazy pavement dermatosis	Normal
Plasma proteins	Markedly reduced	Reduced
Serum enzymes	Low	Normal
Blood urea	Low	Normal
Liver	Fatty infiltration	Normal

FIG. 3.—Child suffering from kwashiorkor showing oedema, skin changes, and moon-face.

Oedema is not seen in these infants, and the liver is free from fatty change. Skin and hair changes are absent.

Hypoproteinaemia is seen in marasmus, but to a lesser extent than in kwashiorkor. The serum protein and albumin concentrations are around 5 and 3.5 g./100 ml. respectively. Blood urea levels are normal, and serum enzyme activity is not much reduced. The major differences between kwashiorkor and marasmus are set out in Table III.

Marasmic Kwashiorkor

These descriptions of kwashiorkor and marasmus are of well-defined cases and may be considered to represent two ends of the spectrum of protein-calorie malnutrition. In practice there is often considerable overlap between these two clinical conditions. In India and Indonesia protein-calorie malnutrition often manifests in the clinical form designated "marasmic kwashiorkor." A picture of marasmus may precede the onset of kwashiorkor in these children. Again, after the disappearance of oedema in response to treatment the subjects may appear marasmic. The differences between kwashiorkor and marasmus are probably not so much due to differences in dietary patterns as to different "adaptation responses" to the deficient diets.

Treatment of Protein-Calorie Malnutrition

Therapy consists in feeding the children diets providing adequate protein and calories. The best protein source for these diets is milk. The therapeutic regimen described in this article is that used in the Nutrition Research Laboratories, Hyderabad.

Each child is given a diet providing 4 g. protein and 200 cal./kg. body weight, the composition of which is given in Table IV. Skimmed milk constitutes 80% of the total protein and wheat 20%. The former is diluted in a ratio of 1:6. The rest of the calories are provided by sugar, bananas, and butter. Since fat gives more calories per unit, butter helps in raising the calorie content of the diet and in keeping the bulk low. These children usually have concomitant vitamin and iron deficiencies, so they are given supplements of vitamins and iron.

TABLE IV.—Diet for Treatment of Protein-Calorie Malnutrition Based on Milk Protein

Ingredient	g./kg. body weight	cal./kg. body weight
Skimmed milk	9	36
Bread	20	70
Butter	7	63
Sugar	7	28
Bananas	2	

Though milk is the best protein for these children, it is expensive and rare in developing countries. Attempts are being made to incorporate locally available vegetable protein foods into these therapeutic diets. Groundnut (*Arachis hypogaea*), Bengal gram (*Cicer arietinum*), and cottonseed have been successfully used. However, these proteins have to be used at a level of 6 g./kg. body weight. Moreover, where possible incorporation of small quantities of skimmed milk gives better results. The composition of one such diet is given in Table V.

TABLE V.—Diet Containing Vegetable Protein Mixture

Ingredient	g./kg. body weight	cal./kg. body weight
Wheat flour	18	63
Cottonseed flour	6	24
Sugar	10	40
Ghee	7	63
Skimmed milk	3	12

The diets are well accepted by the children, though anorexia may restrict the quantities taken in the first three to four days. Clinical improvement, characterized by mental alertness, loss of oedema, and consequent loss in body weight, is evident within seven to ten days. Complete recovery occurs within three to four weeks, when there will have been a gain in body weight and the serum albumin will have returned to near normal levels. Recovery is retarded by the presence of infection, and tuberculosis should always be borne in mind. If it is present a response to therapy will be observed only after the institution of specific antituberculosis treatment. Antibody production is impaired in protein malnutrition, and a negative Mantoux reaction does not necessarily rule out tuberculosis. The practice followed in our clinic, therefore, is that all children who fail to improve with dietary therapy are treated simultaneously with antituberculosis drugs, whether or not they show evidence of the infection.

Troublesome diarrhoea is treated with binding reagents like pectin or kaolin. Where pathogenic organisms are found in the stools specific therapy is instituted. Since most of the cases have diarrhoea, potassium chloride is given routinely.

Vitamin-A Deficiency

After protein-calorie malnutrition the nutritional deficiency most widely prevalent in children of the tropics is that of vitamin A. Some 8% of the child population at any given time have ocular signs of vitamin-A deficiency.

The milder signs of vitamin-A deficiency are night-blindness, Bitot spots, and xerosis of the conjunctiva. The more severe form of vitamin-A deficiency is xerosis of the cornea, leading to keratomalacia, and eventually to blindness. The most common lesion, however, is conjunctival xerosis. Children with a history of night-blindness do not necessarily show any other ocular sign; and children with ocular lesions may not necessarily give a definite history of night-blindness.

The incidence of vitamin-A deficiency is particularly high in children suffering from kwashiorkor, for diets poor in protein are also deficient in vitamin A. Moreover, a close relationship exists between the metabolism of both nutrients. Serum vitamin-A levels are very low in these children, and nearly 65% of the children presenting with this dual deficiency suffer from the most severe form of vitamin-A deficiency, keratomalacia.

Early detection of vitamin-A deficiency, especially corneal xerosis, is vital because administration of vitamin A can reverse the ocular lesion in as short a period as 24 hours. Mild cases of xerosis are often missed owing to examination in poor light.

Treatment

Treatment depends on the severity of the lesion and on the presence of associated protein malnutrition. In children suffering from vitamin-A deficiency alone and in whom there is no corneal involvement 10,000 to 25,000 I.U. of vitamin A daily is administered orally until the lesions disappear, and this usually requires about three to four days. Smaller doses may then be given for a further seven to ten days.

Corneal lesions must be treated as a medical emergency with 50,000 to 100,000 I.U. vitamin A daily until complete disappearance of the lesion. The dose should then gradually be tapered off to 10,000 I.U. Corneal involvement is one of the last stages of vitamin-A deficiency, and the body stores of the child at this stage may be considered to be practically nil. Vitamin-A supplements should be continued for a period of six to eight months. Local application of an antibiotic is advocated until the lesions disappear.

In cases of kwashiorkor with vitamin-A deficiency, contrary to general belief, the oral route of administration is superior to the parenteral route. However, the vitamin should be given with a fat base either in the form of butter or some vegetable oil to facilitate absorption.

Doses higher than those mentioned above are not necessary. It has been found that in a number of children treated with higher doses of the vitamin signs of acute toxicity such as vomiting and bulging of the fontanelle occur. Even at a dose of 50,000 to 100,000 I.U. a small percentage of children may develop these signs, but they are likely to be transient.

Phrynoderma

Phrynoderma, or follicular hyperkeratosis, a nutritional deficiency disorder not uncommonly encountered in the children of the tropics belonging to the low income groups, is a condition generally seen in late childhood and adolescence.

The earlier belief that phrynoderma is a manifestation of vitamin-A deficiency still persists. However, this hypothesis is not substantiated by epidemiological, clinical, biochemical, or therapeutic studies. Vitamin-A deficiency is seen most commonly in the first six years of life, a period at which phrynoderma is relatively uncommon. Many children with lesions of phrynoderma have no other signs of vitamin-A deficiency, and the condition cannot be cured by vitamin-A therapy.

It has been established that phrynoderma is due to a deficiency of essential fatty acids. Vitamin-B complex deficiency also seems to have an associated role, for 60–70% of the patients manifest signs of vitamin-B deficiency.

The disease is characterized by the presence of projecting horny papules on the skin. The papules have a round or oval base and a sharp peak. The papules are generally hyperpigmented, vary in diameter from the size of a pinhead to that of a millet, are discrete, and tend to appear in groups. The lesions are distributed symmetrically, but localized lesions may also be seen occasionally. They are commonly present on the extensor surfaces, especially on the elbows (Fig. 4) and knees,

FIG. 4.—Elbow showing typical lesions of phrynoderma.

and in the gluteal region. They may also be seen on the back and on the posterior and lateral surfaces of the arms and thighs.

Nearly 60–80% of the patients also have signs of vitamin-B deficiency, such as glossitis, cheilosis, angular stomatitis, and nasolabial dyssebacea.

Histopathological examination reveals superficial hyperkeratosis of the epidermis and of the hair follicles. The sebaceous follicles are found to be dilated and plugged with dense keratotic material.

Treatment

The condition can be cured in most cases by the oral administration of fats rich in essential fatty acids. The improvement has been observed to be quicker when vitamins of the B-complex are given simultaneously. Parenteral administration of B-complex vitamins *per se* can also cure phrynoderma, but it has been found that recurrence is more frequent and quicker in such cases as compared with those treated with essential fatty acids. We have routinely employed safflower oil (linoleic acid content: 70%) in doses of 5 ml. thrice daily in combination with an oral B-complex preparation (thiamine 3 mg.; ribo-

flavine 1 mg.; pyridoxine 0.5 mg.; pantothenate 1 mg.; and niacin 30 mg.) with satisfactory results. Improvement is obvious in about two weeks, though six to eight weeks of therapy is needed for complete disappearance of the lesions. It needs to be stressed that even massive doses of vitamin A do not bring about any improvement.

MEDICINE TODAY

Management of Parkinsonism

"*Medicine Today*" is the television series for doctors produced by the B.B.C. Advice on the preparation of the programme is given by the Association for the Study of Medical Education.

The programme on B.B.C. 2 on 5 December was on the subject of Parkinsonism. Printed below is an article prepared with the help of expert contributors to complement the television programme, which will be repeated on B.B.C. 1 on 13 December at about 11 p.m.

Many Parkinsonian patients have now been treated successfully by stereotaxic procedures, and there is considerable agreement on the indications for operation. Young patients with non-progressive and predominantly unilateral tremor often gain gratifying relief; those with marked rigidity may also respond satisfactorily. Frail patients with progressive and advanced disease do poorly, and surgery should be withheld from those with marked hypokinesia, severe disorders of gait and balance, bulbar symptoms, and evidence of intellectual deterioration. Even the most dramatic results are essentially palliative, and successfully placed lesions in selective patients do not alter the natural history of the underlying pathological process. Tremor and rigidity often recur.

Regrettably the greater number of patients are elderly and unsuitable for surgery. Every effort should be made by their doctors to encourage independence for as long as possible. Each patient poses an individual problem in management, and practical advice—from rubber-tipped walking-sticks to strategically placed aids to daily living—is greatly appreciated. Intelligent patients can often teach their doctors useful tips which can be passed on to others. Some patients with postencephalitic Parkinsonism cope remarkably well with stairs and on uneven surfaces. They should be encouraged to persist with these activities despite the anxiety often engendered in their relatives. During transient and minor illnesses patients with Parkinsonism should not spend any longer in bed than is absolutely necessary. After minor setbacks short and intensive courses of physiotherapy are often helpful, but there is little justification for sporadic visits to the clinic scattered over many months.

Drugs are generally disappointing in the treatment of Parkinsonism. Few patients gain dramatic and sustained relief, whereas undesirable side-effects are all too frequent. Though sceptics have related any amelioration of the patient's disabilities to the prescriber's enthusiasm, there can be little doubt that some patients do get useful improvement of tremor and rigidity; and a few show unequivocal relapse when anti-Parkinsonian drugs are stopped abruptly.

Most of the currently prescribed drugs are anticholine compounds, and their use stems from an early clinical observation that belladonna conferred some relief. Today naturally occurring alkaloids such as tincture of belladonna are rarely used, but a host of synthetic analogues are available. There is no convincing evidence that any one preparation is superior to the

others, and there is no rational guide to the sequence of new drugs when others have failed. The general principle is to introduce one drug at a time, beginning with a small dose thrice daily and gradually increasing the amount until optimum relief is obtained or toxic effects become intolerable. This empirical process of adjusting dosage and drug in the hope of discovering a beneficial regimen is often an exacting and frustrating task, taxing the patience and fortitude of both patient and doctor. Visual hallucinations, toxic confusional states, impaired visual accommodation, and excessive dryness of the mouth often cause patients to give up medication spontaneously before their doctor suggests this. Even in a patient who is apparently gaining satisfactory relief it is always worth while stopping treatment from time to time to ensure that the patient agrees that he is better off with his drugs.

Approved Name	Proprietary Name	Tablet (mg.)	Price/100 Tabs.
Belladonna alkaloids	Rabellon		3s. 2d.

Tigloidine hydrobromide	Tiglyssin	250	47s. 6d.

Benzhexol 2 mg. t.d.s., orphenadrine 50 mg. t.d.s., benztropine 0.5 mg. t.d.s., and ethopropazine 50 mg. t.d.s. are approximately equivalent initiating doses of commonly used drugs. Some physicians favour combinations of drugs at sub-toxic levels, but there is no agreement on optimum combinations and certainly little justification for giving more than two drugs at the same time. When increments are made gradually many Parkinsonian patients may tolerate remarkably large doses of anticholine drugs, but it is important to ensure that such heroic measures are desirable and justifiable.

There is little to choose between the various synthetic anticholine drugs, and there is very little mystique in the use of these preparations. Few other useful drugs are available. Dextroamphetamine (5 to 10 mg. twice daily) is occasionally helpful to hypokinetic patients, and antidepressant drugs are often indicated in the management of their chronic and often refractory diseases. Beta-adrenergic blocking agents and dopamine derivatives are still in the experimental stage of assessment, and their safety and place in routine clinical problems has yet to be accepted. Finally, it must be recalled that reserpine, phenothiazines and methyl dopa may cause Parkinsonian syndromes—and these drugs should not be given to patients suffering from disorders of the basal ganglia.

TODAY'S DRUGS

With the help of expert contributors we publish below notes on a selection of drugs in current use.

Griseofulvin

This drug is marketed by Glaxo Laboratories under the name Grisovin and by I.C.I. Ltd. under the name Fulcin-Forte.

History

Griseofulvin, a metabolic product of a mould, was discovered in 1939 in England by Oxford, Raistrick, and Simonart.¹ In 1947 Brian² and Grove and McGowan³ showed it was responsible for a curling action on certain fungi, and it was found to be effective in protecting plants from fungal infection. After another 10 years Gentles⁴ showed that oral griseofulvin was effective in the treatment of experimental ringworm infections in guinea-pigs, and Williams, Marten, and Sarkany⁵ reported its successful use in superficial fungus infection in man. Griseofulvin has since become very widely used and has represented a major breakthrough in the management of various types of ringworm infection. More and more information about its action and use is being learnt, and it is useful at this stage to reassess its value.

Pharmacology

The molecular formula is $C_{17}H_{17}O_6Cl$. The drug is insoluble in water but slightly soluble in various organic solvents. Its fluorescent properties are utilized in quantitative measurements.

In vitro, griseofulvin is active against all ringworm fungi, but it has little or no effect on bacteria, candida, *Malassezia furfur*, aspergilli, and other fungi included in the group of deep mycoses. Its action is to impair the normal development of terminal hyphae, producing distortion and curling.⁶ Although fungicidal, its main effect is fungistatic.⁷ Griseofulvin does not diffuse through the stratum corneum but moves out with the cells from the prickly layer. Fungus can no longer grow on keratin which has developed while the patient is on an adequate dose of griseofulvin. As the drug does not destroy fungus growing in the outer layers of keratin, cure is obtained only when the particular keratin structure infected has completely grown out. Thus the treatment time will be 3 to 4 weeks for skin, 6 to 8 weeks for hair, and 6 to 18 months for nails. Resistance of various fungi to griseofulvin has been demonstrated, but it is very uncommon and usually not complete.⁸

Griseofulvin is absorbed from the gastrointestinal tract, and the blood levels in patients have shown considerable variation after a standard dose. When the drug has been administered after a meal with a high fat content the serum levels may be double those obtained with controls.⁹ In recent years it has been shown that barbiturates administered at the same time reduce considerably the effect of griseofulvin,¹⁰ possibly because the barbiturate stimulates destructive chemical processes in the liver which are also active against griseofulvin. This is an important consideration, as barbiturates may well be given to patients on prolonged courses of griseofulvin, when the effect of the drug will be reduced. The fine particle preparation is absorbed more readily and allows the required dosage to be halved. Although the fine particle preparation has superseded the older form of griseofulvin, the latter is still available as tablets of 250 mg., and confusion has arisen. Unless otherwise stated in a prescription the fine particle preparation is dispensed. Divided doses maintain higher blood levels, and for adults the common dose scheduled is 250 mg. (two tablets) twice per day. Some authorities recommend twice the dose, and this

could certainly be used in the treatment of severe ringworm, or when there is a possibility of partial resistance or poor absorption. The relative amount of griseofulvin required for children is higher, and 125 mg. (one tablet) twice per day is required in most cases. A number of special dosage schemes have been tried. A single large dose such as 2 to 3 g. in children has been successfully used in microsporum infections of the scalp,¹¹ and a once-weekly dose has also been found to be effective. However, it seems that a more certain response is obtained by the usual twice-daily administration.

There have been a number of trials of griseofulvin and its newer analogues applied topically, but these have shown that it has little or no value in the treatment of human ringworm.¹²

Side-effects and Toxic Reactions

Remarkably few side-effects have been reported. Urticarial, morbilliform, and other rashes occasionally occur, but most of these disappear despite continued therapy. A photosensitizing action with subsequent eruption in light-exposed areas has been reported.¹³ Headache, gastrointestinal upsets, thirst, and other minor symptoms may occur, but are rarely severe enough to demand stopping treatment. A curious feeling of distension and fullness in the epigastrium, neck, and face has also been recorded.

Griseofulvin may have some effect on porphyrin metabolism, and Rimington *et al.*¹⁴ demonstrated an abnormality in porphyrins in 21 out of 50 patients on treatment. This, however, seems to be of little practical significance, and does not give rise to any symptoms.

It has recently been shown¹⁵ that griseofulvin has an anti-inflammatory effect, which is in the region of one-third to one-tenth of that of cortisone acetate. This may account for some of the effects which have been claimed on diseases other than ringworm infections.

Clinical Applications

As griseofulvin will act on all ringworm fungi the clinical use can best be considered according to the site involved.

Scalp.—Treatment of scalp ringworm has been revolutionized and x-ray epilation has become a thing of the past. A period of six to eight weeks' treatment is often required, and in small-spore ringworm the hair distal to that laid down while on griseofulvin can still be seen to fluoresce under Wood's light. The cutting off of this distal hair over the infected patches may well stop cross-infection. The natural course of cattle ringworm causing the kerion reaction is to clear after two to three months, but with griseofulvin the treatment time and the severity of the reaction are greatly reduced.

Skin.—Small patches and large areas of infected skin respond to topical fungicides, but griseofulvin will greatly shorten the period of treatment, and perhaps the most dramatic cases treated are where *Trichophyton rubrum* infection has involved large patches, including the hands and feet. However, this is the type of case which often responds to topical fungicides, and recently Davies *et al.*¹⁶ have questioned the use of griseofulvin in smooth skin infections.

Toe-web.—Ringworm involving the skin of the toe-webs is often not cleared by griseofulvin, and in many cases after months of treatment the fungus can still be cultured from the sites. It would seem, therefore, that it should not be used to treat ringworm which has remained localized to the toe-webs.

Nails.—Finger-nails infected with ringworm will take about six months to clear, or longer in older patients. To prevent relapse it is important to treat coincidental ringworm of the

toe-webs with topical fungicides at the same time. Toe-nails will often require one to two years to clear completely, and even after such a period of treatment many are still infected or relapse when treatment is stopped. Particularly in older patients with dystrophic toe-nails it is probably inadvisable to attempt treatment with griseofulvin. Nails infected with *T. mentagrophytes* do not respond quite as well as those infected with *T. rubrum*.¹⁶

Failure of Treatment

Perhaps the commonest cause of failure is the treatment of conditions other than ringworm infection. The differential diagnosis of ringworm from some cases of eczema and psoriasis may be difficult, and mycological examination of scrapings is very important before treatment with griseofulvin is started.

Similarly, fungi known not to respond to griseofulvin may be treated, and in particular candida infection associated with chronic paronychia and *Malassezia furfur* infections (*Tinea versicolor*) are not affected.

The tablets may not have been taken regularly or the drug may not have been sufficiently absorbed. It is worth while stressing the importance of fat increasing the absorption, and the tablets should always be taken after meals. The simultaneous use of other drugs, particularly barbiturates, will reduce the effect of griseofulvin, and this may well have accounted for some reports of failure of treatment.

Resistance of ringworm fungus to griseofulvin is a very unlikely cause of lack of response.

Other Uses

Griseofulvin has been reported to be of value in gout, shoulder-hand syndrome, angina pectoris, psoriasis of the nails, and other conditions. The effect is often slight or unproved, and there does not appear to be any clear clinical application other than in ringworm infections.

The basic N.H.S. cost of 100 tablets of 125 mg. is 26s. 3d.

ANY QUESTIONS?

We publish below a selection of questions and answers of general interest.

Susceptibility to Infectious Hepatitis

Q.—Is a recent attack of tonsillitis likely to make a girl who is to work in a nursery school where there is an outbreak of infectious hepatitis among the staff more open to infection? Is it possible to predict an individual person's proneness to contract infectious hepatitis, and are there any factors which, if taken into account, might make it possible to predict the severity of the illness?

A.—Infectious hepatitis is an acute disease ascribed to one or more viruses whose biological characters have not been precisely determined. The evidence so far is that they are enteroviruses with mainly faecal excretion of variable duration. The mode of infection is the faecal-oral route, and there is a probability that a proportion of those infected do not show overt disease. Children suffer less from the disease in this way than adults, though they may constitute the main source of continuing infection.¹

The number of unknown factors makes it impossible to say whether a recent attack of tonsillitis renders a person more open to infection. This would surely depend more on close contact with persons excreting the virus at the time and on the actual infecting dose of virus transmitted. Contact with school staff and children and the handling and use of common objects, including crockery, would provide opportunities for infection.

There is no way of predicting nonspecific resistance to infectious hepatitis, and, at

present, no suitable laboratory method for measuring specific immunity arising from past infection, inapparent or overt.

In some outbreaks it has been noted that the illness is more severe when there is initial high pyrexia before jaundice develops and when the interval between this pyrexial stage and the appearance of jaundice is short.

Booster Doses of Rabies Vaccine

Q.—A child who was bitten by a rabid dog has completed a therapeutic course of rabies vaccine. Should subsequent booster doses be given, and, if so, how often?

A.—A child who has been bitten by a rabid dog and has completed a therapeutic course of rabies vaccine will not as a rule require any subsequent booster dose. Exceptions to this are when the bite has been caused by a wild animal or when the bites have been severe. In these cases booster doses should be given on the 10th and 20th day after the completion of a full course of vaccine. Vaccines of non-nervous tissue origin, if available, should be used in booster doses.¹

Tests for Connective Tissue Diseases

Q.—What is the relative value of the antinuclear-factor, L.E.-cell, and L.E.-latex tests in the diagnosis of systemic lupus erythematosus and other diseases of connective tissue? What proportion of false-positive and false-negative reactions are obtained when these tests are used for diagnosis of these diseases?

A.—The antinuclear-factor (A.N.F.) test is positive in many forms of connective tissue disease other than systemic lupus erythematosus, and is therefore of little value in the positive identification of that condition. The L.E.-cell test, on the contrary, is highly specific for systemic lupus erythematosus (S.L.E.), with few false-positive reactions apart from certain cases of drug hypersensitivity and of liver disease. Casals, Friou, and Teague² have, however, described a form of nuclear staining characterized by diffuse irregular fluorescence spreading out from the nuclear margin which is much more closely correlated with S.L.E.

The sera from many cases of S.L.E. give precipitin or complement-fixing reactions with D.N.A. and D.N.A.-protein. The L.E.-latex test detects these sera because the latex particles used are coated with D.N.A.-protein. The results with this reagent are more specific for S.L.E. than is the A.N.F. test, but its lack of sensitivity³ makes it unsuitable as a substitute for either the A.N.F. or L.E.-cell test.

Book Reviews

Drugs in the Management of Human Disease

International Encyclopedia of Pharmacology and Therapeutics. Section 6. Clinical Pharmacology. Edited by L. Lasagna. (Vol. 1: pp. 373+xiii, 80s. Vol. 2: pp. 377-667+xiii+index, 63s.) Oxford: Pergamon, 1966.

International Encyclopedia of Pharmacology and Therapeutics. Section 12. Ganglionic Blocking and Stimulating Agents. Vol. 1. Muscarinic and Nicotinic Stimulant Actions at Autonomic Ganglia. By R. L. Volle. (Pp. 110+vii; illustrated, 30s.) Oxford: Pergamon, 1966.

This comprehensive encyclopaedia is at present being published as the various volumes become available and it will undoubtedly become an essential requirement for pharmacologists, clinical pharmacologists, and in fact for all physicians interested in the action of drugs in the management of human disease.

Section 6 deals in two volumes, under the editorial guidance of Dr. Louis Lasagna, with predominantly the methodology of sensible drug usage in man. The editor selected topics in which methodology is stressed, and authors whose views reflect sound principles and who are not dogmatic about transient fashions in drugs in current use. Accordingly, by and large, individual drugs are not dealt with in detail unless their importance contributes to the discussion of the relevant principles. As a result, these two volumes together form a companion of inestimable value to any clinical investigator, and Professor Max Hamilton's chapter on psychotropic drugs should be compulsory reading for all psychiatrists. Lasagna himself discusses with sense and moderation the problems inherent in the assessment of the efficacy of analgesics, and reviews by Professor G. M. Wilson and Dr. A. F. Lant on the evaluation of diuretics and by Dr. William Wilson on hypotensive drugs are excellent.

On the other hand, the chapter on diabetes deviates from the editorial guideline, and rival details are discussed, and, considering their lack of importance in 1967, there is a section on anorexigenics which is inordinately long. In the United Kingdom and else-

where surveys and studies are showing that an appreciable number of people, both at home and in hospital, suffer the consequences of drug treatment, always a legitimate hazard if benefit is likely to accrue from drug use. The Committee on Safety of Drugs in Britain, and the divisions of the Food and Drug Administration in the U.S.A., are increasingly concerned with the detection of adverse reactions, the mechanisms of their causation, and estimates of their true incidence in relation to the extent of drug usage. Only a meagre 12 pages in the 667 pages of these two volumes cover this very large field.

These small criticisms should nevertheless in no way detract from the great value of these two volumes, primarily designed for the clinically orientated medically qualified investigator. In contrast, the first volume of Section 12 is primarily intended for the academic pharmacologist concerned with elucidating precise mechanisms of physiological, biochemical, and pharmacological processes. This volume provides a modern account of the pharmacology of the autonomic ganglion with particular reference to stimulant drugs. As explained in his historical introduction, Professor R. L. Volle seeks to emphasize the gaps and logical weaknesses in the theoretical understanding of mechanisms of ganglionic transmission. Although the basic concept of acetylcholine as the essential mediator in synaptic transmission in ganglia is almost too firmly established to be challenged, the heterogeneity of the cholinceptive sites and the possible role of other transmitters present in the sympathetic

ganglion still require to be clarified. The precise mode of action of acetylcholine itself is still not defined particularly in its relationship to transcellular movements of ions such as calcium.

A quarter of this monograph is devoted to a detailed description of the basic chemistry, pharmacology, and toxicology of nicotine and related compounds, but the section on the clinical treatment of acute nicotine poisoning is out of place in this volume, where it will not be found by those requiring to consult it. Two chapters are concerned with the possible involvement of 5-HT, histamine, the catecholamines, and polypeptides such as angiotensin and substance P in ganglionic transmission. Professor Volle's account of his subject is concisely and clearly written, and he concludes with a plea for further investigations using microelectrode recording techniques to clarify the role of ionic mechanisms in ganglionic transmission.

These three volumes together, for the clinical and laboratory pharmacologists, deal with subjects which should bind closer the two types of individuals interested in drug action. Too often the clinician tends to be empirical and pragmatic without understanding the mechanisms involved in the use of the agents he employs. He will gain immeasurably by consultation with the contributions in Section 6, and his understanding will increase by perusal of Section 12, particularly if it is read in conjunction with Dr. W. Wilson's chapter in Section 6. On the other hand, the laboratory-confined academic and basic pharmacologist, by whom Professor Volle's monograph will be enthusiastically welcomed, will, by a perusal of the two volumes of Section 6 edited by Dr. Lasagna, see with greater clarity the ultimate objective of his work—the development and application of compounds which will prevent or alleviate disease processes in man.

A. G. MACGREGOR.

Genetic and Psychosocial Aspects of Asthma

Bronchial Asthma. A Genetic, Population, and Psychiatric Study. By Denis Leigh, B.Sc., M.D., F.R.C.P., and Edward Marlev, M.A., M.D., F.R.C.P.Ed., D.P.M. (Pp. 192+vii, 63s.) Oxford: Pergamon, 1967.

This fascinating epidemiological study of asthma in the community, carried out on a population drawn from general practice, was conducted by two physicians and a social worker based on a psychiatric hospital. In a world of specialization where boundaries are often jealously guarded this catholic approach is most welcome and this is an interesting and worth-while study planned and documented with great care. The authors have made extensive reviews of relevant literature and drawn attention to serious

deficiencies in some previous studies which now hold a hallowed place in psychosomatic mythology.

The study reminds us that asthma and related conditions are common disorders with a considerable morbidity, carrying a grave risk of superadded chronic respiratory disease. The relationship of asthma to hay-fever, vasomotor rhinitis, childhood asthma, and urticaria is well demonstrated, and the significance of hereditary factors is closely examined. The authors favour a genetic hypothesis and postulate a dominant inheritance with weakened penetrance or a multifactorial inheritance to explain their findings. They found that first-degree relatives of asthma probands had a 43% likelihood of developing asthma.

In some ways the psycho-social aspects of the study are disappointing. A project of this kind must be concerned primarily with the prevalence of defined disorders, and con-

sequently the psychiatric conditions examined were in terms of gross syndromes. It is of some interest that overt psychiatric illness was no more common among adult asthmatics than in the control group, though childhood psychological disturbance was significantly more frequent among the asthma probands, both reported as prevailing in those subjects under the age of 12 years, and as reported retrospectively in older patients. There was a significantly greater incidence of neurosis in the first-degree relatives of the asthmatic group, with females more frequently affected.

While this book is intended for the specialist rather than for the general reader, the details of design and execution of the study, the review of the literature, and the wealth of factual data ensure that it will be read with interest by workers in diverse fields.

S. BRANDON.

A Hole in One...

is always unexpected, but so are lots of other things in life. Have you guarded against the 'unexpected', by providing for your family, should you not live?

The greatest need for protection is when the family are young. Have you made sufficient provision for them?

The Medical Insurance Agency can arrange the right policy to suit individual needs. Why not seek advice now?

MEDICAL INSURANCE AGENCY LIMITED

BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

Telephone: EUSTON 6031/9 (STD: 01 EUS 6031/9)

Telegrams: MEDINAGE, LONDON, W.C.1.

'Good mornings'...

begin with dry nights

Many cases of functional enuresis respond favourably to 'Tryptizol' Syrup. Clinical evidence has shown that this well tolerated antidepressant (in a pleasant-tasting syrup) provides a valuable therapy to accompany the physician's reassurance and advice. Only one dose daily is required, to be given at bedtime.

'Tryptizol' Syrup

Amitriptyline pamoate

Merck Sharp & Dohme Limited, Hoddesdon, Hertfordshire
Telephone, Hoddesdon 67123

Each 5 ml (teaspoonful) contains
10 mg amitriptyline (as the pamoate).
Detailed information is available
to physicians on request.

Doctors Versus the Government

The New Zealand Doctor and the Welfare State. By J. B. Lovell-Smith. (Pp. 222; illustrated. 32s. 6d.) Auckland, New Zealand: Blackwood & Janet Paul. 1966.

This is a sober account of a fierce controversy which raged for over a decade between the New Zealand Branch of the B.M.A. and the Socialist Government of that country, and the story is of interest to those in this country who were, or are, engaged in a similar conflict with Government here. The author is a general practitioner in Auckland, and the hero, to whose memory the book is dedicated, is J. P. S. Jamieson, M.D., F.R.A.C.S., who in 1950 was a B.M.A. gold medallist and who placed all his files at the author's disposal.

A Bill to establish a compulsory national insurance scheme had been introduced in the New Zealand Parliament as early as 1883 but had been rejected; in 1900 New Zealand was the first country in the world to establish a ministry of health. The first medical problem it tackled was that of the hospitals, which had developed erratically, mainly with Government subsidies; however, by 1938 the system of public hospitals was deemed to be "of high quality." In 1935 the first Labour Government was elected, and in the same year a departmental committee was appointed to consider the question of a national health insurance scheme, together with the reports on the matter previously prepared by the Combined Hospital Boards and the New Zealand Branch of the B.M.A. The Branch gave evidence to the effect that a national health insurance scheme could not be expected to reduce the volume of illness and that the need was for proposals to prevent ill-health. The dedicated Socialists pressed for a salaried medical service and the abolition of private practice.

The battle raged fast and furious for many years. Dr. Guy Dain, as he then was, and Sir Henry Brackenbury visited New Zealand. The Government gradually shed the more objectionable items of its policy and became reconciled to payment per item of service, which was fixed in 1941 at 7s. 6d. The main dispute revolved round whether the State should contract with the doctor or with the patient. The final outcome was that the doctor claimed on the Social Security Fund for his 7s. 6d. but was not precluded from making an additional charge to the patient, who, however, had the safeguard that the doctor must send a detailed account. If the patient thought that this was excessive he could send it to a local investigating committee, who were empowered to reduce it. In 1941 the supplement paid by the patient was generally 3s., but by the time the book was written it had grown to about 7s. 6d. for a surgery attendance and 10s. for a home visit. In the early days, when many doctors charged the patients their ordinary fee and the patients made their own claim for a part refund from Social Security, the administrative cost of each refund was 1s. 6d. The whole basis of professional reward was altered; the general practitioner earned more than the specialist, and by comparison the earnings of those on salaries were "ridiculous." The author admits that the system "can rightly be regarded as open to abuse" and that abuses did occur in the early days.

During the past decade the population has increased by 12% but the number of practising doctors by 55%. Every general practitioner has free access to radiology and to laboratories for pathological examinations.

The book has a good index, but none of the 28 chapters has a heading and the exact chronology of events is hard to follow. However, the Labour Party lost the general election of 1944, since when there seems to have been peace.

ALLEN DALEY.

Comprehensive Review of Pituitary Function

The Pituitary Gland. Edited by G. W. Harris, M.A., Sc.D., M.D., D.M., F.R.S., and B. T. Donovan, B.Sc., Ph.D. (Vol. 1. Anterior Pituitary. Pp. 586+xiv; illustrated. Vol. 2. Anterior Pituitary. Pp. 670+xiv; illustrated. Vol. 3. Pars Intermedia and Neurohypophysis. Pp. 678+xiv; illustrated. Set of 3 volumes £26 5s.) London: Butterworth, 1966.

This is an opportune moment for this book to appear. Most of the pituitary hormones are defined and some have been synthesized. Many can be measured by immunoassay in body fluids, so that their role in physiology and in disease is being specified. The control of the endocrine system by hypothalamic neurosecretion is also now being defined. In these three volumes recent findings are set in perspective against the well-established data. It should provide a reference book for teachers and research workers of lasting value, though unfortunately the price may exclude this book from many private collections. It is, moreover, readable and well supplied with illustrations and charts.

Each chapter offers a readable and concise review of its field up to about 1964. The authors for the chapters are authorities from U.S.A., New Zealand, France, Italy, Sweden, Denmark, as well as the United Kingdom. Some chapters are wordy and sometimes one joint chapter might have been better than two or three separate ones. The three volumes are: Volume 1, Anterior pituitary (anatomy and biochemistry), Volume 2, Anterior pituitary (mainly its control), and Volume 3, Pars neuralis and intermedia. This book aims to cater for electron-microscopists and biochemists, as well as for clinicians.

Fortier gives an excellent and concise review of the control of A.C.T.H. secretion suitable for the clinician; other chapters review the physiology, the chemistry, and the non-endocrine actions of A.C.T.H. The chapter on the physiology and chemistry of growth hormone reviews also its relation to diabetes mellitus, acromegaly, its assay in body fluids, and also its use in the treatment of dwarfs. The physiology and chemistry of T.S.H. is fully covered, including its assay in plasma and the problem of exophthalmos. The gonadotrophins and mammatrophin or prolactin are extensively reviewed, though more in relation to animals than patients. Excellent reviews are included of the neurohypophysis in relation to kidney function and to vascular reactions, as well as the chemistry of vasopressin, and syndromes of inappropriate A.D.H. activity. Other chapters review hypophysectomy in man and in animals,

clinical tests of pituitary function, pituitary tumours in man as well as their experimental production in animals, and also the question of pituitary regeneration.

Several chapters will appeal more to research workers. A comprehensive review on the cytology of the adenohypophysis achieves a synthesis of this still unsettled field. The regulation of gonadotrophins in various species is extensively reviewed, though unfortunately in two separate chapters. The several chapters on the neurohypophysis unfold interesting details of the neurosecretion of vasopressin and oxytocin, their synthesis in the supraoptic nucleus their binding to the carrier protein neurophysin, and their propulsion down the axons to feet lying on the capillary walls in the posterior pituitary. A good introduction is offered to the hypothalamic releasing factors and their portal control of pituitary function, which is a field likely to have increasing relevance to medicine.

RUSSELL FRASER.

Revised "Hamilton Bailey"

Hamilton Bailey's Emergency Surgery. 8th edition. Edited by T. J. McNair, M.D., F.R.C.S.(Edin.), F.R.C.S.(Eng.). (Pp. 1026+xv; illustrated. £8 8s.) Bristol: John Wright, 1967.

Deplorable though it may be, much of the emergency surgery throughout the world today is carried out by junior men under less than ideal circumstances and without the direct supervision of an experienced surgeon. Moreover, more than the fair share of these cases seem to occur in the middle of the night, when the surgeon is already tired from his day's work and has little assistance from the now closed laboratory or x-ray department. It was for these humble, unsung, but essential young men, as well as for the benefit of their emergency cases, that the late Hamilton Bailey produced the first edition of *Emergency Surgery* in 1930. It was an immediate and well-deserved success, but lapsed after its seventh edition in 1958 with the unfortunate death of its author, sadly enough following an emergency operation.

Mr. McNair and his team of assistant authors must be complimented on a very fine revised edition. It combines the three essentials which the emergency surgeon requires in a reference book: succinct descriptions of disease (often with helpful case reports), clear indications of when and when not to operate, and detailed accounts of the operative procedures to employ. The illustrations are an important feature, and, as befits the late author, are of a very high standard.

As in every major textbook which has gone through many editions, here and there one detects somewhat outmoded features. One would like to see a description of the Fogarty catheter technique for peripheral embolism, for example, and few surgeons nowadays would stress the high Fowler position. These are minor comments on what is a really valuable major textbook. It will continue to prove of immense comfort to the surgical registrar, and will be read with profit and enjoyment by his chief.

HAROLD ELLIS.

International Population Trends

Proceedings of the World Population Conference, 1965. Vol. 2. Fertility, Family Planning, Mortality. (Pp. 510+xiii. \$7.50.) New York: United Nations Department of Economic and Social Affairs. 1967.

Representatives from 88 countries attended the World Population Conference held in Belgrade in 1965, and over 500 scientific and technical papers were given. The proceedings were published in four volumes. Volume 2, published this year, comprises 103 papers and 75 short summaries of other papers which had been presented. The proceedings reported in this volume have been arranged under eight headings: (i) Future population trends and prospects; (ii) Fertility; (iii) Factors and patterns of fertility in areas where fertility is relatively high; (iv) Factors and patterns of fertility in areas where fertility is relatively low; (v) Studies relevant to family planning; (vi) Mortality; (vii) Mortality, morbidity, and causes of death; and (viii) Population genetics.

The topics under discussion allowed for a great deal of speculation and the views presented were those of the authors. Some of the views, perhaps because of the limited space allowed for the article, appear to be unsubstantiated. Some of the opinions expressed on future population trends were undoubtedly biased either because of ideological beliefs or by national outlook. The consensus of opinion seems to be that birth control must play an important part in any population policy. One Russian worker thinks that a possible population of 5,000 million by the year 2000 could be well fed if the people were equipped by the methods of modern science and technology. Another worker suggests that the world area under cultivation can be increased by $2\frac{1}{2}$ to 3 times its present size. If the capitalistic theories of production did not stand in the way there would be no need of birth control, and using the methods of western Europe it would be possible to feed over 30,000 million people. In the speculations on the amount by which food production can be increased the need for living space seems to have been minimized. In Western countries the area available for food production is diminished

each year by the pressure of the population for increased living space. Ironically sites on which it is easiest to build new towns, reservoirs, motor ways, aerodromes, etc., are the best farm lands.

The papers on fertility are interesting but not very informative, because of their shortness. Some papers are accounts of pilot surveys based on rather small numbers in a very limited area of a country. Whether the results of these surveys can be extrapolated for the whole country is a matter of opinion, but large-scale inquiries will be necessary to establish trends. Economics, religion, and tradition are the major factors affecting fertility, but the environment of the people is an important factor that affects the differences between countries, especially developing countries.

Mortality and morbidity are influenced to a very large extent by the standard of living of the population and by the standard of medical care that it can afford. The section on mortality and morbidity is mainly concerned with the position within individual countries, and although international comparisons are attempted these are affected by the differences in the methods of registration and the classification of the causes between countries. In a large area of the world the care of the sick is undertaken by non-medically qualified persons—e.g., herbal doctors, witch doctors, etc. This section of the volume gives an interesting account of the large increase in medical care that has occurred in the U.S.S.R. The number of physicians, including Army medical officers, rose from 28,000 in 1913 to 501,000 in 1963.

The last section of the book deals with some of the aspects of population genetics. The difficulties inherent in this study are outlined in the various papers.

The multiplicity of books in recent years make it necessary to ask whether a new book fills any particular need. It can be assumed that the object of the World Population Conference, to provide an opportunity for workers in the same field to make each other's acquaintance and discuss mutual interests, was achieved. This volume suffers from the same defect as most accounts of symposia. It is a record of the proceedings, but whether the papers make any new contribution to knowledge is, perhaps, open to doubt, since in general the papers are short summaries of

work that has been published elsewhere. If the United Nations Organization thought it desirable to publish an account of the present state of knowledge on population subjects it should not have been beyond its powers to produce a coherent statement.

W. J. MARTIN.

Use of E.E.G.

The E.E.G. in Clinical Practice. By John Laidlaw, M.B., Ch.B., F.R.C.P.Ed., and J. B. Stanton, M.A., M.B., F.R.C.P.Ed., F.R.C.P., D.P.M. (Pp. 128; illustrated. 40s.) Edinburgh and London: E. & S. Livingstone. 1966.

This is a well produced and clearly written introductory account of the clinical uses of the simplest types of standard electroencephalographic techniques. After a good description of techniques and artefacts, the bulk of the book is occupied by what the authors call "clinical situations," that is, common clinical conditions in which the E.E.G. might be expected to help. The illustrations are excellent and the comments pertinent, particularly the authors' insistence on the value of the E.E.G. being enhanced if clear and appropriate questions are asked rather than diffuse requests for " ? epilepsy."

There is a short chapter at the end entitled "The Future of the E.E.G. in Clinical Practice," which refers particularly to the use of sleep records in temporal lobe epilepsy, and serial recordings in hepatic encephalopathy. One would have thought that both these situations were very much of today rather than the future. The whole book, in fact, is disappointingly conservative. There is no reference whatever to any underlying neurophysiology, so that the techniques are presented like a sort of static photograph of that little bit of cerebral activity which current electronic amplification apparatus can produce for us.

As a crammer book for those neurologists and psychiatrists who want to have a passing acquaintance with the E.E.G., the volume may have some value, but unfortunately it is only too likely to confirm such readers and others in a jaundiced view of clinical neurophysiology that is increasingly out of date.

MEDICAL EDUCATION

Postgraduate Medical Education

A report¹ published this week calls for an overall plan of action for postgraduate medical education in Britain. Even twenty years after 1948, it states, there is no real co-ordination of effort or objective, particularly in vocational training, and today this is still the key question. "The formation of the Scottish Postgraduate Medical Association in 1962 was a promising step, but with only powers of persuasion and no money, how effective has it proved in helping to solve the major problems of the day? In 1967 the initial objectives of the Central Committee [for Postgraduate Medical Education] gave no hint of crisis or emergency."

According to the report the whole question of postgraduate education has been bedevilled by the way in which specialist status has become continuous with consultant rank in the National Health Service. "Particular specialties doubtless require particular qualities of mind and will, but a career structure should not imply a competition in which some succeed and are trained and some fail and drop out." In the report's view three main elements are missing at present in the arrangements for postgraduate education: a structure, both for postgraduate and continuing education; adequate finance; and a mechanism for co-ordination.

Need for Structure

The report was commissioned by the Nuffield Provincial Hospitals Trust to explore the responsibilities of the various bodies concerned in postgraduate medical education. Discussing the lack of a structure for vocational training in the National Health Service, it emphasizes that sufficient training posts for the various specialties must be provided. So far there has been little effective supervision of training posts as a whole, even though, in the case of senior registrars, the universities work closely with the regional hospital authorities. Hence, the report suggests, there must be an independent authoritative central body, both to demonstrate the need for a training structure and to approve and supervise training posts.

The report continues by saying that, though at present the Ministry of Health has the paramount influence on postgraduate training, there is no evidence that there is an overall plan of action. The Ministry has already outlined the regional postgraduate organization it considers necessary, but, the report says, it is not clear what part the universities and colleges are to play in this, and regional hospital boards must be given a

clear lead. Furthermore, the particular sum spent on postgraduate education by a particular regional board has to be decided according to its other commitments; hence there are considerable differences in the provision of postgraduate schemes among the various regions. In the report's view, moreover, there is one notable outstanding anomaly—namely that, in contrast with their counterparts in teaching hospitals, few consultants in regional hospitals have any teaching element recognized in their contracts.

At present the Central Committee for Postgraduate Medical Education is intended only to be advisory, but the report questions whether it can continue this role if it is to perform a useful function. If it is to start influencing events it needs quickly to enlarge its aim beyond the one already outlined (a review of preregistration posts). On the other hand, the report emphasizes that the committee's potential influence is very great, and its support of the Fellowship Scheme for advanced clinical studies may have been a factor in the prompt approval given by the Ministry for a substantial grant. The report expresses surprise that the constitution of the committee does not include representatives from the Ministry, as the Minister is ultimately responsible for the standards of medical care. "The Ministry of Health appears to have been holding back from the assumption of too much authority in this field in the hope that the gap will be filled in another way; but it is inevitable—and proper—that it will be forced into greater intervention if the vacuum is not filled."

Specific responsibilities suggested for the Central Committee might include implementing the standards for specialist registration, if these are laid down by the General Medical Council; co-ordinating the efforts of the service and educational authorities in postgraduate training; and commenting judiciously on the effectiveness of the career structure for the specialties. The Central Committee could delegate the approval and supervision of training posts and the form and content of training to the colleges; while the responsibility for service matters could be delegated to the regional postgraduate medical committees.

Finance

The report says that the future financing of the Central Committee will require special consideration, and it is a weakness that as long as the committee consists only of educational members—as at present—it

can hardly look for continuing support outside the universities and colleges. Substantial funds will be needed to carry out the functions suggested above and to enable the committee persistently to inquire into the content and method of postgraduate medical education. Nevertheless, in relation to postgraduate medical education as a whole the amount of money needed for its long-term stability and security is said not to be very great, provided the vast potential of the universities, the colleges, and the regional postgraduate committees is exploited through delegated powers. It would seem desirable, the report considers, to look more optimistically to the Ministry of Health as the prime source of funds rather than to the University Grants Committee, and it cites the Ministry's financing of a nursing research unit (see p. 628) as a precedent.

Role of Central Committee

Discussing the role of the Central Committee, the report says that this can really gain in authority only if it were to become the key adviser to the Ministry on postgraduate medical education. It might be in the nation's best interests that the committee should be seen to be independent and should be made responsible for monitoring all matters concerning postgraduate medical education in the National Health Service. Nevertheless, there must be provision for dialogue with the Ministry and its satellites.

Concluding, the report says that the Central Committee is at present the best focus that exists or is likely to exist for some time. Its first real test will be how it faces up to deciding what is necessary to bring some order to the chaos of the immediate post-registration phase. "Finally it is not too optimistic to believe that to fulfil its potential, the Committee need not depend on being granted statutory powers of direction or sanction. There is already a miscellany of bodies wielding a wide range of powers in the field of postgraduate medical education, which derive from statute or long tradition. Indeed, what is now required is possibly the influence and authority that stems from the cool considered views of an intellectual élite, suggesting the form of a society rather than a board of management. Perhaps the Central Committee is indeed the start of a British Academy of Medicine."

CONFERENCES AND MEETINGS

Tropical Splenomegaly Syndrome

[FROM A SPECIAL CORRESPONDENT]

A one-day symposium was held at the Royal Postgraduate Medical School in London on 17 November. The participants comprised experts in tropical medicine, parasitology, pathology, immunology, and haematology, most of whom had had personal experience with splenomegaly in the tropics. They met to review the present state of knowledge and to define those areas where further research was likely to be fruitful.

Splenomegaly is common in tropical countries, and well-recognized causes include portal hypertension due to hepatic cirrhosis, haemoglobinopathy, leishmaniasis, and schistosomiasis. In some areas there exists a form of massive splenomegaly found mostly in adults in which the above causes can be excluded. This type of splenomegaly has been termed idiopathic splenomegaly, tropical splenomegaly, "big spleen" disease, cryptogenetic splenomegaly, Bengal splenomegaly, and African macroglobulinaemia. The disorder is found in regions where malaria is endemic, and it has been customary to consider malaria a causative factor, although the evidence in favour is largely circumstantial. Many interesting features have been described as a result of studies by workers in Uganda, Nigeria, New Guinea, and elsewhere using modern techniques.

The majority of participants favoured a noncommittal title of tropical splenomegaly syndrome, at least for the time being. It was pointed out that a syndrome only has been described, which may not, in fact, be a homogeneous entity in all areas studied. A more definite title should wait until further work has produced a clearer understanding of the causal mechanisms.

Role of Malaria

Much of the time was spent discussing the evidence in favour of malaria being the cause. Massive splenomegaly has become less common in Calcutta and Algeria since the control of malaria in these regions. In Uganda this form of splenomegaly is not found in areas free of malaria but is common in other parts.

There are pockets of high incidence of the disorder in valleys at an altitude of 3,000 feet (914 metres) and above in New Guinea, where the pattern of malaria transmission is likely to be unstable. Affected persons in Uganda show high titres of fluorescent malarial antibody in the serum, though it was pointed out that the interpretation of this type of test is difficult and that high titres do not necessarily indicate a state of immunity to malaria.

The most conclusive evidence that malaria is implicated in the aetiology of the syndrome was provided by a group of workers in Ibadan, who have obtained beneficial results with continuous antimalarial therapy. Proguanil was the drug chosen, and it was given in a daily dose of 100 mg. There was a slow but progressive diminution in the size of the spleen (over a matter of months) associated with correction of anaemia and an improvement in general health. This occurred despite the fact that malarial parasites could not be found in the blood of these patients before treatment. It was emphasized that in some cases therapy had to be continued for more than a year before maximum reduction in spleen size was achieved, in many cases the spleen becoming palpable. Cessation of therapy caused the spleen to enlarge once more, full relapse taking about three months. It was the opinion of the meeting that lifelong anti-malarial therapy was likely to benefit patients with the tropical splenomegaly syndrome provided that medical surveillance was possible. Chemotherapy probably decreased acquired immunity to malaria and should not be used for long periods without recognition of this effect. Splenectomy was not indicated, since the risks of bacterial infections and fatal attacks of malaria in subjects after splenectomy were considerable.

An Abnormal Immunological Response?

Massive splenomegaly in adults is not the usual reaction of immunity in areas where malaria is endemic and transmission stable,

and it is likely that some special factor or factors operate to produce the syndrome in susceptible people. Affected subjects show few or no malarial parasites in peripheral blood films and there is lack of malarial pigment in the reticulo-endothelial cells in biopsy material—both features usually being associated with immunity. There is no real evidence that poor nutrition is a contributory factor. Perhaps infection with a combination of species of malarial parasites or an unusual frequency of challenge may produce an abnormal immunological response, resulting in massive splenomegaly.

Anaemia is a usual finding in the tropical splenomegaly syndrome, and recent isotope studies have shown the causes to include pooling of red cells in the enlarged spleen, increased rates of red cell destruction, and expansion of the plasma volume. The mechanism of hypervolaemia is obscure. Another interesting feature of the disorder is an abnormality in serum-immunoglobulin concentrations. There is an increased amount of the immunoglobulin IgM in the serum, this finding in general being more marked in those patients with the larger spleens.

The descriptions of the syndrome from different regions of the tropics showed some variable features. In Nigeria peripheral blood and marrow lymphocytosis might be found, and it was suggested that lymphoproliferative disorders might be more common in such patients. This lymphocytosis was not seen in New Guinea or Uganda. Splenic histology in New Guinea patients was reported to show more dilatation of sinuses and less lymphoid proliferation in the pulp than was observed in Africa. Splenomegaly was more frequent in the Rwanda than in the Baganda tribe, living in the same area of Uganda. There was some evidence from Nigeria that possession of the sickle-cell gene might give some protection from the development of massive splenomegaly. The disorder was more common in women than in men in both Africa and New Guinea. Finally, the relationship of the tropical splenomegaly syndrome to cryptogenetic splenomegaly in Hong Kong—which is often associated with hepatic cirrhosis—was unknown.

Aspects of Anxiety

[FROM A SPECIAL CORRESPONDENT]

Any discussion of anxiety must begin with a definition of the term, and a variety of definitions were put forward by participants in the World Psychiatric Association's symposium on "Aspects of Anxiety" held at the Royal College of Physicians in London from 13 to 15 November. Professor MAX HAMILTON (Leeds) distinguished three uses of the word in the senses of a normal reaction to danger, a pathological mood, and a disorder or syndrome—anxiety state or anxiety neurosis. Dr. LOPEZ IBOR (Madrid),

President of the W.P.A., reminded the audience that the present time had been referred to as an age of anxiety, perhaps because of the rapid changes in society, but that anxiety was presumably a feature of the human condition which had always existed. He felt that pathological anxiety differed from normal anxiety in its intensity. "If one *troubles*, the other *disturbs*." The amount of anxiety reached a pathological degree when it transcended the subject's ability to bear it; either the flow of painful stimuli was

overwhelming or the total lack of stimuli, as in sensory deprivation, was frightening.

Measurement of Anxiety

Professor H. J. EYSENCK (London) showed how experimental psychologists had constructed a model of anxiety with respect to its origin, its behavioural effects, and its differences in different persons. This model had a certain amount of coherence and experimental support and might be helpful to

psychiatry. In terms of modern learning theory the primary drive for anxiety was pain; neural stimuli associated with pain caused fear responses which resulted in a secondary drive stimulus of anxiety.

Dr. M. H. LADER (London) pointed out that from the standpoint of psychophysiology there were two approaches to the investigation of anxiety. Attempts might be made to induce anxiety in normal subjects or psychiatric patients by various stimuli, or differences might be sought between patients complaining of anxiety and normal subjects. Several physiological values could be used for study of anxiety, mostly in the realm of the autonomic nervous system—such as blood pressure, heart rate, finger pulse volume, or skin conductance. A reciprocal relationship existed between anxiety and depersonalization; thus values such as skin resistance underwent great change in anxious patients with episodes of depersonalization.

Dr. J. SMYTHIES (Edinburgh) dealt with the central brain mechanisms involved in anxiety. Fear reactions seemed to be controlled in general by a complex system, including the limbic structures and in particular the amygdala, hypothalamus, and reticular formation. Swedish workers had related these mechanisms to chemical findings, for they had shown that, whereas the cortex mainly runs on acetylcholine, the limbic system, hypothalamus, and reticular formation contained large quantities of noradrenaline and serotonin, and there were actually different neurons with specific chemical transmitters—noradrenaline, serotonin, and dopamine. He had also been able to relate the action of the hallucinogen mescaline—an analogue of adrenaline—to the anxiety level in the subject; terrors and psychosis tended to be induced in people with a high resting level of anxiety or those who became frightened during the experimental use of the drug.

Dr. M. VARTANIAN (Moscow) had shown that intravenous injection of serum from anxious patients into rabbits led to a rise in noradrenaline content of the hypothalamus, quite apart from the usual stress reaction due to injection of foreign serum. He had also demonstrated autoimmune reactions in persons under intense stress, for the serum of patients in acute psychotic states frequently contained antibodies to brain proteins, as did that of 40–50% of normal subjects under intense stress.

Dr. J. BOWLBY (London) said that the cause of the separation anxiety in children deprived of their mother was something of a puzzle, but recent work on affectional bonds in birds and mammals might hold the clue. The bonding and attachment behaviour of animals presumably served the purpose of protection from predators and was probably not related primarily to food or sex, as had been suggested in the past. Just as the bonded animal temporarily separated from its mate would search for the latter and exhibit distress until it was found, so the human adult who had lost a spouse would for a while after bereavement go through a period of behaviour which could be interpreted as a search for the lost object, as Dr. C. MURRAY PARKES (London) showed from his studies of widows.

Separation anxiety could also be manifested as a result of separation off by a political system, and Dr. W. VON BAEYER (Freiburg) discussed his studies of the victims of political persecution in the Third Reich, at least one-third of whom retained appreciable lasting psychiatric effects of their experiences.

Genetic and Environmental Factors

Studies on twins by Dr. ELIOT SLATER and Dr. J. SHIELDS (London) had shown that inherited factors played a part in predisposing to anxiety. Nevertheless, the environmental factor might often be the dominant one.

The President of the Symposium, Dr. W. SARGANT (London), devoted much of his presidential address to his conviction that drug treatment of anxiety was of paramount importance, after pointing out to his hearers that anxiety was perhaps the major psychiatric problem of the day, as shown by the 43 million prescriptions for psychotropic drugs issued by practitioners in the National Health Service in a recent three-year period, mostly for anxiety and tension. He reiterated his

faith in the monoamine oxidase inhibitor group of antidepressants in the management of phobic anxiety states in persons of good previous personality, and in the usefulness of antidepressant drugs in general, perhaps combined with electroplexy, in depressive tension and anguish. He felt that there was still a place for frontal leucotomy in patients without response to drugs or electroplexy.

Dr. M. GELDER (London) was concerned with the efficacy of specific desensitization in the treatment of anxious patients with isolated phobias. He considered this treatment superior to either group or individual psychotherapy, but only as regards removal of the phobia. Desensitization did not lower the level of general anxiety.

A specialist in physical medicine, Dr. F. COOKSEY (London), drew attention to the frequent failure of doctors to take into account and assess the degree of anxiety accompanying physical disabilities, as exemplified by the patient with low back pain or a stroke. Ideally any department concerned with rehabilitation should have a psychiatrist working in it, and he should be consulted early and not as a last resource.

NEW APPLIANCES

Grooved Probe Dilator: Aid to Vascular Anastomosis

Mr. D. G. A. EADIE, senior lecturer in surgery, the London Hospital, writes: An instrument has been designed to facilitate the anastomosis of small blood vessels where accurate insertion of the corner suture is

The probe dilator (Fig. 2) is constructed of polished stainless steel to prevent injury to the vessel endothelium. The head is detachable from a malleable copper rod to permit thorough cleaning. Four different-

FIG. 1

FIG. 2

essential to achieve a perfect technical result. It has a threefold function: firstly, the groove allows the needle to be placed and recovered with ease—that is, at the corner of the vessel to be sutured (Fig. 1); secondly, the probe itself acts as a dilator; and, finally, once the probe is in position it acts to steady the vessel, thus eliminating the need to grasp the vessel with dissecting forceps.

sized heads are available, ranging from 4 to 7 mm. in diameter.

This instrument is available from the Genito-Urinary Manufacturing Company Limited, 28a Devonshire Street, London W.1. The prototype was made by Mr. F. H. Watson, of the London Hospital instrument department.

Correspondence

Letters to the Editor should not exceed 500 words.

Medical Science: Master or Servant?

SIR,—It is refreshing in these days of diminished personal responsibility in public affairs to read Lord Platt's Harveian Oration (25 November, p. 439), for, in case some innocent readers might not suspect it, he was a professor of medicine during a period when he might have been supposed to exert some influence. Despite the number of chairs in medicine and therapeutics, which he considers large, expansion is a very recent one, so that, for example, ten years ago only about half of the London teaching hospitals had such chairs, and it is perhaps not surprising that the departments concerned were, and still are, particularly interested in studying the phenomena and causation of disease, since this provided the first challenge in caring for patients.

Unlike Lord Platt, I think that in this country this represents a considerable advance within the last twenty years, and it might put matters into slightly better perspective if the often markedly limited physical and financial conditions of many of these university medical units were looked at realistically. There is no substitute, however, for the first-class idea which can be brought to fruition in even the most unpromising conditions, but the environment and attitude towards many university medical units has left much to be desired. He also fails to point out that the "therapeutic explosion" was occurring at precisely this time also, and while there is no doubt that university medical departments played little direct part in this, apart from the reasons given, I think a major cause is the previous lack of biochemical and pharmacological tradition in the training of doctors. This situation is being remedied quickly. How is it possible within the framework of the present organization of medical research to bring more first-class ideas to fruition unless departments of medicine are expanded? Many can see as clearly as Lord Platt that the study and development of the action of drugs or of psychological factors in disease are pressing problems, but in order to create a new post in my own school with the sort of person I hoped would produce such ideas I was compelled to turn for financial support to the pharmaceutical industry in the hope that ultimately the university could take over the enterprise. Since the university works on a quinquennial basis, it may readily be seen that speedy action is difficult. I am sure that most of the current professors of medicine can see the problems clearly enough, and I am sure that they would find it considerably easier to help in the advances and changes in direction of scientific and medical effort if it was as easy to translate thoughts into action in the current university setting as Lord Platt seems to find it in retrospect. Since I believe there are people with first-class ideas in university departments of medicine, I

would like to suggest that one of the ways to give them opportunities for the developments that many would like is to change the concept of departments of medicine as they currently exist in this country.

Despite his strictures on the American approach to the problem, I believe that a university hospital should have a large all-embracing department of medicine in which it is as easy to employ a physicist as a physician who, without ever doing any research work, demonstrates the highest of skills in the care of patients. The error of the American approach has been its emphasis on research of any standard to the exclusion of clinical skills in giving positions in university departments, and this is something which I am sure we can avoid. Nevertheless, the atmosphere of co-operation and enthusiasm with high-class work which characterizes many of these departments is something I would dearly like to see reproduced more widely here. It seems to me that our most pressing problem is how to bring about this transition quickly in our current financial and intellectual situation. Our so-called university hospital system is inelastic and still overmuch attached to separatism within the clinical sphere.

The main revolution that has to occur is in the mind as well as in the organization of medicine, and I think that Lord Platt is grievously wrong in contrasting the understanding of patients and their needs with the scientific aims of medicine. We can keep out the dangerous fools attached to machines as long as we can let in the wise men. This is where we need the real leadership in our profession which will bring about a synthesis and understanding and not the continuation of old divisions.—I am, etc.,

St. Mary's Hospital,
London W.2.

W. S. PEART.

SIR,—In congratulating Lord Platt (25 November, p. 439) on his brilliant account of the misdirected efforts now wasted on certain types of clinical research, may I offer statistical confirmation of two of the points he makes?

His statement "that sex education was taboo until quite recently" I can confirm by the research I did on the types of sex education medical students received in the universities of this country.¹ From 47 medical schools questioned 36 replies were received, 24 from Britain and 12 from abroad. Less than half of the students at these medical schools entered their professional life with any adequate equipment to deal with these problems, and I have reason to believe that the position is not very different today.

I can also confirm Lord Platt's statement of the almost complete neglect of psychological factors in my own subject of infertility,

where so often the treatment of her (and occasionally his) genital organ is all that the sterile couple receives. That 25% of all cases presenting at my clinic have infertility of emotional origin² is statistical confirmation of Lord Platt's thesis that "scant attention has been given to the ills of the mind of man and woman and the study of their behaviour in health and disease and in society."—I am, etc.,

Cheadle,
Cheshire.

Hospital Boards

SIR,—If my friend Mr. R. G. Macbeth's description (25 November, p. 482) of the struggle for power is a true reflection of the state of the Health Service in most of the regions in England I can only be thankful that so much of my medical life has been spent in Scotland.

Yet, even north of the border, Mr. Macbeth seems to consider that at least half the teaching hospitals exist in a state of frustration and annoyance owing to the interposition of the regional hospital board between them and the Scottish Home and Health Department. On what authority he bases this assumption is not stated, but, as a former clinician who has had the experience of serving on all the bodies mentioned in his letter, in addition to occupying at the present time the post of a temporary medical administrator, I feel I am in a position to correct some of his statements.

It has always appeared to me from conversations I have had with my colleagues in England that the retention of the boards of governors of teaching hospitals as a separate body fostered a state of internecine warfare between boards of governors of teaching hospitals, regional hospital boards, and the university faculty, and that the two primary objectives for which these bodies existed—namely, the welfare of the patient and the education of the student—were liable to suffer. Mr. Macbeth's solution is to abolish the regional hospital board, but might not the better plan be to do away with the boards of governors of teaching hospitals as such and replace them by group boards of management as in Scotland?

No one would pretend that there is never any area of disagreement between regional hospital boards and boards of management in Scotland, but this is seldom serious, and, if necessary, an appeal can be made to the Scottish Home and Health Department by a board of management. In general, I believe boards of management and the university recognize that the regional hospital board has a useful and specific function in formulating policy and determining priorities. Provided communications are good, this will eventually operate to the advantage of all, and in my opinion since the Health Service started

there has been very considerable progress in the improved interrelationship and harmony between the university, boards of management, and regional hospital board. Mr. Macbeth's solution seems to be for the Ministry of Health to allocate to smaller area boards than the regional hospital board a block grant, the exact slice of the financial cake being determined by the Ministry as it thought fit. In other words, there would be no body of local opinion to guide the overall distribution of financial resources. I very much doubt if one can designate such a policy as being one of devolution, and I venture to think that under Mr. Macbeth's scheme the smaller areas would be likely to receive a less equitable share than they do at present, since there would be a greater tendency for the Ministry to place most of their goods in the show-rooms of the teaching hospitals for political purposes.

The second part of Mr. Macbeth's letter deals with the composition of the boards of governors of the teaching hospitals, and here I think there is probably room for reorganization, but in Scotland this is more likely to be concerned in the first instance with the recommendations of the Brotherston working party contained in their recently issued report on the Organization of Medical Work in the Hospital Service in Scotland,¹ which, if they are adopted, will certainly involve the medical staff in a greater share in the organization of the teaching hospital than is the case at present.

Finally, I feel it is a mistake for Mr. Macbeth to leave even the faintest implication that the boards of governors of the teaching hospitals have a monopoly of integrity and service in the Health Service.—I am, etc.,

Aberdeen.

Managing the Hospitals

SIR,—In recent months the management structure of hospitals has been the subject of many investigations with the expressed view of improving efficiency at all levels and making the most of the available resources. These investigations have given rise to a spate of reports—for example, Farquharson Lang (Scotland),¹ Hawnt (Northern Ireland),² and the most recently published King's Fund (London) report.³ It is now quite obvious that these important reports are receiving scant attention from hospital doctors, because they have not been made aware of their content and are thus unable to investigate them fully and assess their eventual effect.

It is suggested that there is now a case for all levels of hospital medical staff to examine and assess their individual roles in the hospital structure of the future, and consider if any benefit is to be derived from the application of recognized managerial principles in their own work. These principles are based on an analysis of business and commercial efficiency. Their acceptance, in part or *in toto*, without critical examination and recognition of the unique structure and function of a hospital could prove disastrous to the efficiency of hospital medical practice. The medical profession can be proud of the

standard of efficiency in the majority of our hospitals, and should recognize that if industry, the Civil Service, and other administrators had matched this in their own spheres then much of the stagnation of our present-day economy would never have occurred. The fact that continued and steady progress has been made in the hospital service where levels of authority are difficult to define, and where variations occur from region to region, is an argument in itself for retaining the existing flexibility. The same considerations weigh heavily against the introduction of "super managers," which most of these reports favour.

It is significant that the idea of a "super manager," who would in most cases be a lay administrator, originated from committees and working parties composed almost entirely of hospital secretaries and other laymen, who are completely unqualified to investigate the subjects under review. It would not be uncharitable to suggest that a "Charter for Hospital Secretaries" would be an apt title for their various recommendations. In most cases these working parties have decided their own terms of reference and do not appear to have gathered the detailed and impartial evidence on which their opinions should have been based.

The influence of the Institute of Hospital Administrators can be seen clearly in the recommendations contained in these reports. Their views were made clear when asked by the Ministry of Health for their comments⁴ on the Salmon Report on Nursing⁵: "Today hospital administration can no longer be viewed in the simple terms of comprising a partnership of medical, nursing, and lay administration. In the complex of the modern hospital medicine and nursing are only two of a wide range of essential services." They declare that the Bradbeer concept of tripartite administration "has become regarded as wholly outmoded by both hospital administrators and by others concerned with the management of the hospital service."

It is imperative that the medical profession realize that these reports carry implications as great as did the original introduction of the National Health Service. They should not allow less important preoccupations to detract from the recognition of the magnitude, the scope, and the far-reaching effects of these reports. The lay take-over of hospital administration by all-powerful general managers, most of whom would be "lay," would eventually reduce the status of medical staff to the level of all other groups of hospital workers. These reports infer that the medical profession can play no worthwhile part in the running of the hospital service. The interference with professional freedom and the doctor-patient relationship which would eventually follow the introduction of such systems would unquestionably ruin our hospital service for all time, and would make hospital medical practice an unattractive and unrewarding career.

The present reorganization of the general-practitioner service will eventually locate most general practitioners in group-practice centres owned by local authorities. It does not require a great stretch of the imagination to see this branch of the profession eventually fall under the thumb of lay administrative managers.

All doctors should unite now to face this great challenge to our profession and its freedom. The British Medical Association should ensure that the maximum amount of

publicity is given to the implications contained in these reports. The response to your leading article (4 November, p. 252) indicates a lack of interest by the profession, who do not appear to be aware of the gravity of the situation which is now facing them, and unopposed implementation of these reports through lack of interest is very likely to occur. The medical profession and the British Medical Association should ensure that "medical administration" is added to the curriculum of undergraduate and post-graduate medical training as a matter of the utmost priority to ensure that a supply of top-quality medically qualified administrators will be available to fill the managerial breaches now being artificially created.—We are, etc.,

Clomiphene for Ovulation

SIR,—Your leading article (25 November, p. 434) states that "to determine whether a woman responded at all to clomiphene and when she ovulated requires nearly continuous 24-hour collections of urine for steroid assays over two to three weeks." But surely all the non-ovulating infertile woman wants is to conceive and the only test that interests her is a pregnancy test.

How many busy housewives or working women can collect 24-hour specimens daily for three weeks? How many laboratory units in how many hospitals can do the necessary estimations and do them daily for three weeks on a considerable number of women without getting literally inundated with urine? Your leading article cites this as "an example of a situation where the skilful use of laboratory resources can be of great benefit to a few people while a failure to use them can do harm to a larger number." What harm? Your leading article states that the untoward side-effects of clomiphene are slight, so even if it is given to many women who do not need it, as it undoubtedly will be, or do not respond to it, it will not do them any harm. It is obviously waste of time and clomiphene to give it to women with regular ovulatory cycles, because its only therapeutic function is to induce ovulation. Most of our cases, however, have been patients with long-standing secondary amenorrhoea or oligomenorrhoea with only two or three cycles a year, in whom ovulation obviously does not occur or occurs only very seldom.

It is of course important to select suitable cases so far as possible, and urinary gonadotrophin or oestrone estimations are helpful for this purpose. It is also important to weed out those cases that do not respond to clomiphene at all, for it becomes inappropriate to go on treating them for more than three or four courses, though some women who do not respond to the first course may do so to the second or third course. But to

weed the non-reactors out it is quite unnecessary to make them collect all their urine for three weeks. The induction of uterine bleeding 10 days to a fortnight after the treatment shows that there has been some response. Basal temperature recording will show in the majority of cases whether ovulation has taken place and may indeed be the earliest indication that conception has taken place. Serial vaginal cytology (vaginal smears taken daily or on alternate days) will give an accurate indication of the oestrogenic response, the induction of ovulation, and the post-ovulatory progesterogenic response. Women of even moderate mental capacity can be taught to take their own smears, and they can bring them up to the clinic once a week, once a fortnight, or even once a month. All that is needed is a vaginal cytology unit to interpret them. At present there are very few. There should be more. If there were a great deal of unnecessary routine steroid hormone estimations on 24-hour urine specimens would be avoided and steroid chemists would be able to get on with their research work.—I am, etc.,

Neutropenia Caused by Methyldopa

SIR,—So far as we are aware only two cases of neutropenia caused by methyldopa (Aldomet) have been recorded,^{1,2} and therefore we think it worth while to report a third.

A Persian doctor's wife aged 43 consulted us because of pain in the back. This was found to be due to osteoarthritis. In the course of routine examination she was found to have a blood pressure of 200/120 mm. Hg. The urine was normal in all respects. An intravenous pyelogram and a renal arteriogram showed nothing abnormal. Methyldopa and a low-calorie diet were prescribed. Her blood pressure fell satisfactorily. After 10 days her temperature rose to 102° F. (38.9° C.) and a white cell count showed a total of 2,000 with 800 neutrophils. Methyldopa was discontinued and ampicillin prescribed. Three days later the leucocytes were still 2,000, and the neutrophils had fallen to 460 per cu. mm. A marrow examination by Dr. M. J. L. Patterson showed the following results—Cellularity: reduced. Erythropoiesis: normoblastic and somewhat depressed. Granulopoiesis: markedly depressed. Megakaryocytes present and appear normal. Reticulum cells infrequent. Plasma cells normal. Mitoses reduced. Iron present in normal amounts.

Thereafter the white cell count improved. After a further five days the total leucocytes numbered 3,000 per cu. mm. with 1,290 neutrophils. By the end of three weeks the leucocyte count had risen to 4,000 and the neutrophil count to 2,160.

One difference between this case and Dr. K. G. A. Clark's¹ is that, whereas his showed active granulopoiesis to the metamyelocyte stage, in ours granulopoiesis was much depressed. There was no evidence of autoimmune haemolysis which methyldopa occasionally causes: the red cell osmotic fragility was normal, the serum bilirubin 0.4 mg./100 ml., and the direct antiglobulin test negative.—We are, etc.,

Low Back Pain

SIR,—Although it is now commonly believed that defects in the neural arch (spondylolysis) are stress fractures rather than congenital in origin,^{1,2} it is quite misleading to suggest that such stress fractures of the pars interarticularis are common findings in patients with low back pain ("Medicine Today: Low Back Pain," 11 November, p. 341). Furthermore, it is rare to find a defect in the pars interarticularis which can be shown on serial x-rays to go on to unite. Perhaps this is because the forces acting on the lower lumbar vertebrae tend to separate the fracture surfaces.

Defects of the neural arch, with or without an associated forward slip (spondylolisthesis), are more commonly found in association with chronic low back pain, and 7.9% of a total of 4,411 patients from four series quoted by Rowe and Roche had defects demonstrable on x-ray. When symptoms occur they are the result of the mechanical weakness or lumbar instability³ resulting from the defect, and are the same as those seen in lumbar instability from any other cause, such as degenerative disease of the lumbar spine.⁴ When conservative treatment fails the logical treatment is spinal fusion⁴ to stabilize the unstable segment, a form of treatment not mentioned in your article.—I am, etc.,

SIR,—As I presume your "refresher" column on back troubles (11 November, p. 341) is intended to help general practitioners, I think it should be remarked that the clinical picture as described differs somewhat from that seen in general or industrial practice, where loss of the ankle jerk in sciatica occurs in a comparatively small minority of cases, and muscular weakness or wasting are excessively rare except following surgical intervention.

Further, the observed natural history of the syndrome leaves one in no doubt of the common origin of lumbago and sciatica, from intervertebral disc lesions, without the need for aetiological differentiation.

Lumbago is usually a mild condition, and, while one cannot doubt the wisdom of strict bed rest for a first attack in the slender hope that full healing may take place, when the condition becomes recurrent, with an admitted frequency of about two attacks a year, this advice is not only overcautious but quite impractical. In fact the majority of cases of lumbago improve most quickly with the earliest possible mobilization, and in what must be thousands of cases in industrial practice I have never once seen the threatened sequelae of urinary or other sinister complication.—I am, etc.,

Congenital Dislocation of the Hip

SIR,—Your leading article (18 November, p. 371) on the admirable study of hip-dislocation by Dr. H. V. L. Finlay and his colleagues (same issue, p. 377) raises a point which perhaps needs a brief comment. You state that congenital dislocation of the hip is congenital but is "not a genetic defect in the same class as the developmental errors like harelip, cleft palate, and absent or supernumerary fingers." In fact none of these conditions are entirely genetically determined, but there is an important degree of genetic predisposition for all of them. The evidence for this in twin and family studies is as good for congenital dislocation of the hip as for cleft lip and palate, and rather better than for most instances of absent or supernumerary fingers.¹ On the other hand, if you are using "genetic" not in the sense of determined by genes but in the older sense of developmental (timing and the class of morphological abnormality involved) your statement is of course valid.

The familial aggregation of congenital dislocation of the hip is of some practical importance. Even where all babies are screened for the condition it is worth, for example, examining a baby girl whose brother or father had congenital dislocation of the hip with special care; just as it is worth examining a little girl who is first-born and breech-born with special care.—I am, etc.,

SIR,—Dr. H. V. L. Finlay and others are to be congratulated on their study of congenital dislocation of the hip in the newborn infant (18 November, p. 377). They give a valuable description of Barlow's tests and rightly emphasize the importance of direct palpation of the head of the femur. Unfortunately your leading article tends to blur the distinction between the Barlow and Ortolani tests. The distinction between these tests is of vital importance.

In Ortolani's test¹ the knee is held with the hip flexed and the hip is then slowly abducted. In the dislocated hip reduction of the joint will occur with a palpable "jerk" or "jolt," which is usually visible. ("Click" is not a good translation of the Italian "sbalzo" and "scatto"). Ortolani emphasized that his test was practically identical with the Lorenz manoeuvre for reduction of congenital dislocation of the hip. It is therefore effective only if the hip is actually dislocated. For this reason it will not always detect congenital dislocation of the hip in the early stages when the hip is merely unstable or where the hip slides in and out of the acetabulum without a jerk or jolt. Ortolani did not in fact recommend the test in the first three months of life.

Barlow's test,² on the other hand, is designed specifically for use in the newborn and the first three months of life. The hip is held in a pincer grip between the thumb in front and the middle finger behind. In this way when the flexed hip is abducted pressure

of the middle finger will reduce a dislocated hip and pressure of the thumb will dislocate an unstable hip. The essential feature of Barlow's test is that the hip joint is palpated directly by the hand, and slipping the head of the femur in or out of the acetabulum is appreciated by direct digital palpation. Barlow's test is therefore not only more sensitive it is also more accurate than Ortolani's. It detects the unstable hip in the early stages; it also eliminates the clicks which can occur in the absence of any hip instability. Expressed in other words, Barlow's test demonstrates very early "slips," whereas Ortolani's test demonstrates somewhat later "jerks."

The confusion which has arisen between these two tests is perhaps due in part to Mr. Barlow's modesty in describing his own test as a modification of Ortolani's. It is in fact based on different principles. Ortolani's test (like the old "telescoping" test) is an indirect examination in which an attempt is made to assess the hip by manipulating the shaft of the femur. Barlow's test, on the other hand, as Dr. Finlay and his colleagues rightly emphasize, does not involve any manipulation of the shaft of the femur; the examining hand goes straight for the hip joint. I do not think that Barlow's test will ever be adequately understood until we cease to speak of it as a "modified Ortolani" test and until we get rid of the idea that we are looking for a "click."—I am, etc.,

Mushroom-worker's Lung

SIR,—Dr. C. T. B. Adams (18 November, p. 421), referring to my paper on mushroom-worker's lung (16 September, p. 708), describes a solitary case of a mushroom worker with general and respiratory symptoms, radiological pulmonary nodulation, negative serum precipitin test, and a scalene lymph node showing sarcoid features, and concludes that his patient is suffering from sarcoidosis and not from mushroom-worker's lung as I have described it.

Assuming that Dr. Adams's patient was in fact suffering from sarcoidosis, this does not rule out the possibility that he was in addition suffering from mushroom-worker's lung. In a proportion of cases of farmers' lung the serum precipitin test is negative. Only if the patient were re-exposed at the mushroom farm and his reactions observed could one be certain that he was not suffering from mushroom-worker's lung.

However, the demonstration of sarcoid histology in one lymph node does not justify a diagnosis of sarcoidosis unless there is good supportive evidence, which should include due consideration of possible environmental hazards. I would suggest that two other explanations are possible in Dr. Adams's case. Firstly, the patient might have been suffering from a "non-sarcoid" condition of the lungs, and the sarcoid histology of the scalene lymph node represented merely a local sarcoid reaction. Such local sarcoid reaction in lymph nodes draining, for example, pulmonary neoplasms are well

recognized.^{1,2} Secondly, the patient might have been suffering from mushroom-worker's lung, but the so-called sarcoid histology of the scalene lymph node represented a lymphatic spread from the pulmonary lesions. The histology of farmer's lung at an early stage shows a granulomatous appearance similar to sarcoidosis. Although there has been no previous report of such a case, Dr. Adams's patient could be the first to have shown this phenomenon.

Dr. Adams speculates about the possibility of precipitins in the blood of my Cases 1 and 2 having persisted from previous farming jobs. A careful occupational history was taken, and neither of them had any other farming experience before commencing work at the mushroom farms.

The patients described in my paper showed such a clear-cut relationship between the development of their clinical and radiological features and their exposure at the mushroom farm that there could be little doubt that their condition was a variety of extrinsic allergic alveolitis, and quite distinct from sarcoidosis.—I am, etc.,

Institutional Care of the Mentally
Subnormal

SIR,—I have been following with considerable interest the recent article by Professor T. McKeown and Dr. I. Leck (2 September, p. 573) and subsequent correspondence (11 November, p. 355) on the care of the mentally retarded in England and Wales. What puzzles me is why a better defined policy for their care has not emerged before now, since provision has been under way since 1913. All that appears to be happening is a process of hair-splitting between what is or is not a medical-nursing concern, what is deemed skilled and unskilled care, and an attempt to farm out certain types of mentally retarded children, and I assume adults, too, between health and education authorities. Those who work closely with the mentally subnormal cannot but hold the view that theirs is usually a lifelong need, from the cradle to the grave, and so continuity of care is essential. A piecemeal project is both wasteful and frustrating. Integration of the services dealing with them is advocated in recent reports.

In Northern Ireland since 1949 there has been operating a service for the mentally subnormal which avoids dichotomy of responsibility.² Here the care of the mentally subnormal, who are legally designated "persons requiring special care" by the Mental Health Act (Northern Ireland), 1948/61 is vested in one authority—namely, the Northern Ireland Hospitals Authority—as part of the hospital and specialized services. The authority is responsible both for the community care and the hospital or residential needs of all those found to be persons requiring special care. The authority has designated the day-to-day administration of this duty to three special-care management committees. Each regional committee carries out ascertainment, the provision of care in the community, including junior and senior schools (training centres), sheltered workshops, hostels, clubs, etc., and hospital and residential accommodation as is required. This arrangement facilitates the

change of care from community to hospital as circumstances dictate.

Such a unified control has enabled the needs of the subnormal to be assessed and provided for, subject of course to financial control, with that single-mindedness of purpose essential to obtaining speedy results. This is reflected in that from starting in 1949 some 1,283 places have since been created in day special-care schools or centres and hospital accommodation for some 1,363 patients. As well, hostels for 26 girls and 20 boys have been opened. A total of 5,624 are on the special care registers out of a population of some 1,458,000.³

The training of both nursing and teaching staff is undertaken within the hospital precincts. Psychological services are engaged in diagnostic and research projects in association with other disciplines such as speech therapy, physiotherapy, and social work. An active employment service also functions for trained boys and girls. In all of this close liaison is maintained with other agencies such as education, health, and welfare authorities, general practitioners, and the general hospitals. The parents and friends of the mentally handicapped not only contribute generously towards our free funds for the patients but also take an active interest in the standards of care and training extended to those in need. In return, counselling advice is offered regarding problems of the mentally retarded and their management.

It is suggested that co-ordination of the services for the subnormal is the most sensible approach.—I am, etc.,

Deaths from Tuberculosis

SIR,—Dr. A. Pines (18 November, p. 416) rightly draws attention to one aspect (drug-resistance) of the problem of deaths from tuberculosis. In England and Wales the total deaths in 1966 from tuberculosis were 2,354, and no fewer than 525 were persons not notified before death as suffering from tuberculosis.¹

The Research Committee of the British Tuberculosis Association, with the help of the Ministry of Health and General Register Office, is to conduct a national inquiry into tuberculosis mortality. A letter is shortly to be sent to all chest physicians inviting their co-operation. They will be asked to give details of the circumstances of every death attributed to tuberculosis in their own districts between 1 February and 30 April, 1968.

The main purpose of this inquiry is to determine the nature of any avoidable factors, both clinical and administrative, which contributed to a death ascribed to tuberculosis and whether the death can be strictly attributed to active tuberculous disease or its treatment and was therefore preventable.

The comparable inquiries into maternal mortality carried out by the Ministry of Health have contributed significantly to the

reduction of deaths in that field. We hope to publish our findings in a similar way.—I am, etc.,

PETER DAVIES,
Research Committee,
British Tuberculosis Association.

Tongue Pain and Giant Cell Arteritis

SIR,—Dr. A. H. Henderson (11 November, p. 337) draws attention to the importance of pain in the tongue as a feature in giant cell arteritis. We have found glossitis in 12.6% of a series of 87 cases of temporal arteritis.^{1,2} The glossitis varied from gangrene of the anterior two-thirds of the tongue to a sensation of burning. Commonly the tongue was raw-beef red and sore. There were also examples of blistering and bruising, and this, together with the pathogenesis of other skin lesions in giant cell arteritis, has led us to suppose that in vascular areas such as the tongue, scalp, and face necrosis is due to haemorrhage rather than occlusion.³

We agree with Dr. Henderson that the tongue should be examined in every case where giant cell arteritis is suspected, as it may present important confirmatory evidence.—We are, etc.,

Cross-infection in a Surgical Unit

SIR,—Dr. J. E. Tinne and others (11 November, p. 313) acknowledge that the addition of colistin to the routine post-operative drip may be essential in combating the type of infection reported. They do, however, caution, "... its nephrotoxicity must be borne in mind."

To date no positive histopathological evidence has been offered to support the claim that colistin is nephrotoxic. The evidence from animal studies¹ is that when massive doses (19.2 mg./kg./day intraperitoneally) are given to rats and mice only very slight congestion with tubular necrosis can be detected; at levels of 9.6 mg./kg./day no such changes are seen. For such effects to appear in man, therefore, a dose of about 1,152 mg./day would be required, which is some 4½ times the recommended dose. In humans no histological evidence of damage was found in 11 renal biopsies² following therapeutic doses of colistin, although Katz,⁴ using an excessive dose (15.4 mg./kg./day), believed that in one patient nephrotoxicity was apparent, but the findings suggest that the lesion was regressing.

The question of nephrotoxicity must therefore be discussed in the light of reports of elevated blood urea nitrogen and plasma creatinine levels in patients receiving colistin for urinary infections⁵ or in healthy volunteers.⁷ A fall in blood urea nitrogen during therapy has also been found,⁶ and the effect on renal function is clearly dose-dependent.^{8,9} Even so, doses of up to 720 mg./day have been used without affecting blood urea

nitrogen,¹⁰ and in conditions of elevated levels prior to therapy (>50 mg./100 ml.) no further change has been attributable to colistin.¹¹ The reason for these variable transient and reversible changes in blood urea and creatinine in some cases is not clear. It has been suggested³ that colistin may be vaso-active, reducing renal blood flow and glomerular filtration rate, although this has been challenged⁴ on the basis of one case.

Clearly, so far as we are aware, no irreversible damage to the kidney has been demonstrated, and, whatever the significance of the observed blood changes, it is still held^{3,6} that the administration of colistin is of such therapeutic benefit as to allow its controlled use even where renal dysfunction is proved. As has rightly been pointed out by Dr. Tinne and his colleagues, there is an increasing hazard from Gram-negative infections in hospitals, especially due to *Ps. aeruginosa*, which may be located in the sputum of staff members. A recent paper¹² describes successful management of patients with positive sputum culture by combined intramuscular and aerosol colistin. This regimen resulted in therapeutically effective blood levels without involvement of the kidney.—We are, etc.,

Which Stethoscope?

SIR,—On the basis that some 3% of adults are sufficiently hard of hearing to need hearing-aids there are several hundreds of general practitioners and others in this country for whom the article by Drs. C. S. Hampton and A. Chaloner (18 November, p. 388) is merely of academic interest, since they would hear practically nothing through even the most efficient stethoscope. Many

practitioners, although deriving benefit from their hearing-aids in their private lives, are prevented from using them in their professional work because of the difficulties involved in the concurrent use of an aid and the traditional binaural stethoscope.

So long as the hearing-aid has a microphone cut-out switch, however, there is no reason why a transistorized stethoscope should not be used with the ear-insert in situ. The essential components of a home-made (or do-it-yourself) transistorized stethoscope may be found in any hearing-aid repair department. The minor modifications in wiring of the components are well within the scope of anyone with a minimum of electronic know-how and take only a few minutes. The photograph illustrates the compactness of the gadget and the ease with which it is used. Almost its only disadvantage is that it is a two-handed instrument; when used with a sphygmomanometer the chest-piece has to be tucked under the cuff or else held in position by the patient. I shall be pleased to supply details of the electrical modifications to anyone interested.—I am, etc.,

91 Embankment Road,
Plymouth, Devon.

BERNARD PECK.

SIR,—Congratulations on the article "Which Stethoscope?" (18 November, p. 388). Can we have some more on the same lines? For example, "Which Ophthalmoscope?"—I am, etc.,

Oxford.

R. P. RYAN.

Cardiac Involvement in Psittacosis

SIR,—We have noted with interest the account of a case of psittacosis myocarditis by Dr. R. Coll and Dr. I. Horner (7 October, p. 35). We wish to report a similar case.

Our patient was a boy aged 13. He was small and obese, and had not attained puberty. When admitted to hospital (30 September 1967) he gave a history of dyspnoea, cough, and expectoration of about three weeks' duration. At first his sputum had been mucoid, but later it became purulent and was finally blood-stained. He had also suffered from nausea, retching, upper abdominal discomfort, and diarrhoea. On examination there was moderate overfilling of the jugular veins, and the liver was enlarged about 2 cm. There were crepitations throughout the lung fields. The heart rate was 140 per minute, and the pulse was thready in character; the blood pressure was 95/60 mm. Hg. The apex beat was heaving and was 2 cm. to the left of the mid-clavicular line in the fifth left intercostal space. Radiological examination revealed moderate generalized cardiac enlargement, and suggested the presence of a small pericardial effusion. The electrocardiogram showed a general low voltage pattern.

Digoxin, frusemide, and tetracycline were given. At first there was some reduction of dyspnoea, but the heart rate was unaffected, and nausea and retching persisted. Four weeks after admission he developed a pleural effusion and soon after this he died suddenly. Necropsy confirmed the diagnosis of myocarditis and the presence of a pulmonary embolus. These findings were considered to provide an adequate explanation of the patient's sudden death.

During the illness specimens of serum had been sent to the Regional Virus Laboratory, Ruchill Hospital, Glasgow. The only abnormal finding was the presence of anti-

body to the psittacosis group of organisms in titres of 1/1024 (3 October), 1/256 (12 October), and 1/64 (23 October). When the serological reports were received inquiry revealed that the patient had recently been in contact with budgerigars which were kept as domestic pets.

The history, the clinical picture, and the serological and post-mortem findings seem to warrant a diagnosis of psittacosis with cardiac and pulmonary signs. The persistent nausea and retching have not yet been explained. When further necropsy reports are available and the results of virus isolation studies have been completed we intend to publish a more detailed account of this case.—We are, etc.,

Deaths from Exposure

SIR,—The annual winter toll of deaths from exposure begins this year with the loss of two African officer cadets on Dartmoor.¹

Wide publicity has been given to the dangers of wet and cold by the mountaineering societies.² The necessity of extra food and clothing, the importance of the early recognition of signs of fatigue, and the suicidal folly of travelling light appear to be widely known except perhaps in Army circles.

What is apparently not so well understood is that judgement is impaired by bad conditions before physical signs of exhaustion develop. Young men whose judgement has already been impaired by the necessity to show determination, drive, and enthusiasm, and who may in addition fear failing the course if they show prudence, are particularly likely to make wrong decisions. The inexperienced will tend to press on, and bring severe trouble upon themselves or other people.

Imperative instructions to abandon the operation in the event of deterioration of weather or the physical condition of the participants ought to be part of the briefing for this sort of training by ordeal. Without this it is likely to be unnecessarily costly.—I am, etc.,

FRANCES MARGARET ULYATT.

Varicose Ulcers and Use of Topical Corticosteroids

SIR,—I have read with great interest the letter on the above subject by Dr. C. D. Evans and others (25 November, p. 482).

As a general practitioner with considerable interest in dermatology I am well aware that current thinking certainly appears to suggest that the use of corticosteroid ointments, either with or without antibiotics, leads to the rapid extension of stasis or varicose ulcers. This

point was particularly emphasized by Dr. R. P. Warin in his excellent article on "Advances in Treatment of Skin Diseases" in last October's *Practitioner*.¹ Unfortunately this does not always seem to be borne out in practice from a general-practitioner point of view. I can think of numerous cases where the use of such an ointment has stimulated healing.

I am at present treating a case of a very large varicose ulcer of the right leg of some weeks' duration. In spite of the usual methods of treatment, including pressure bandaging, etc., this ulcer failed to heal, and eventually disintegrated into a dirty sloughing sore involving a large area in the lower third of the leg. As the patient refused to attend a dermatological clinic I eventually (in desperation) used an ointment containing oxytetracycline hydrochloride B.P. and hydrocortisone B.P. After one week there was dramatic improvement in the ulcer and after two weeks (two days ago) there was considerably more improvement, the ulcer now being half the size in width and depth, perfectly clean, with no evidence of secondary infection present.

If the use of corticosteroid increases the extension of the ulcer, one would expect to be confronted with a perfectly clean, dry lesion (due to the action of the antibiotic on secondary infection) but with a more penetrating ulcer due to the cortisone. Does the fact that this is not always so depend on the amount of time for which the corticosteroid has been applied or perhaps on some other factor like the pH of the lesion? Might there not be some synergistic action between steroid and antibiotic in certain cases? On the other hand, is this just a case of the dermatologist seeing only the general-practitioner failures and not their successes?

I should be grateful for your readers' views.—I am, etc.,

Glasgow S.3.

Abortion and Conscience

SIR,—Dr. Myre Sim (4 November, p. 297) exhorts those of us without religious objections to abortion to heed our medical consciences. He is so convinced of the rightness of his views that he brands any doctor who acts differently as lacking in conscience. I do not agree with this assumption. Many highly conscientious doctors favour abortion on social grounds. In the present state of knowledge it is still open to question whether in a particular family the addition of an unwanted child will endanger the health of the other children. We recognize the strong association which criminality and psychiatric disorder have with emotional and material deprivation in childhood, but these associations are not invariable nor can accurate predictions be made in the individual case. Many of us, while supporting Dr. Sim's call for more research, feel that available evidence is strong enough to warrant action.

The history of medicine abounds with instances where far-sighted action brought advances which, had they had to await incontestable evidence, would have been long delayed. John Snow removed the handle of the Broad Street pump 30 years before the cholera vibrio was isolated. For most of us it takes courage to recommend or to perform

an abortion. It is an operation from which we shrink with a natural abhorrence. How much easier it is to do nothing, especially if inaction can be condoned by invoking "medical conscience."—I am, etc.,

ALAN SANDERSON.

Housing and Health

SIR,—Wing-Commander D. M. Fanning (18 November, p. 382) in his masterly analysis of the effect of flat-dwelling on health draws attention to the increasing incidence of neurotic illness in flat-dwellers.

Is it not possible to lay this lamentable consequence fairly and squarely at the doors of the architects? It appalls me, on visiting patients who live in flats, to find perhaps 100 people living in one building, all in separate rooms with absolutely no common meeting-ground apart from the entrance hall. The appalling loneliness of flat-dwellers is accentuated many times over by the enforced juxtaposition of others in the same condition.

The provision of a common dining/sitting/recreation-room where free-and-easy contacts could be encouraged would of course not solve the problem entirely. It would, however, be a step of the utmost importance from the point of view of psychological hygiene. It is time the medical profession insisted on such a provision in the construction of all future multi-storey flats.—I am, etc.,

Huddersfield,
Yorks.

S. L. HENDERSON SMITH.

"Big Spleen" Disease

SIR,—In preliminary studies we have shown that in some patients with "big spleen" disease abnormal splenic uptake of ⁵⁹Fe in labelled red cells in vivo is reduced following antimalarial therapy. This effect was not seen in patients with hypersplenism due to other causes.

These early observations lend experimental support to the recommendation by Drs. E. J. Watson-Williams, N. C. Allan, and A. F. Fleming (18 November, p. 416) that antimalarial therapy should be given an extended trial in the treatment of suspected "big spleen" disease.—We are, etc.,

Carcinogenicity of Tobacco and Tobacco Smoke

SIR,—Dr. H. P. Beckett's view (2 September, p. 614) that the carcinogenic factor(s) seems to be contained only in the smoke inhaled from the superheated area of the cigarette is, to say the least, doubtful.

Laboratory animals do not smoke, and it is the same yellow-brown condensate, tobacco tar, that stains the fingers of man that is painted on their skins. That carcinogens are present is therefore equally certain. As the available epidemiological and experimental data are not adequate to fix a safe dosage

of chemical carcinogens below which there will be no response in man,¹ the absence of papilloma and carcinoma in the stained fingers of man to date is surely significant.

The naive histological demonstration of Dr. F. J. C. Roe and Mr. A. L. Levene (2 September, p. 615) does not have adequate relevance either. Had they demonstrated unchanged epidermal thickness in the stained fingers of heavy cigarette smokers (20 and more per day for 20 years and more) and non-smokers of comparable age, sex, and occupation in addition, they would have a leg to stand on. Nor did I ask if tobacco smoke is a carcinogen for man either. What I asked was (5 August, p. 373) whether the absence of "cigarette-smoker's finger," and the fact that not all heavy cigarette smokers develop lung cancer, did not argue for some other essential factor, in addition to cigarette smoke, for the evolution of malignant disease in any particular heavy cigarette smoker. To date I have had no answer.—I am, etc.,

Dose of Phenoperidine

SIR,—My attention has been called to a typographical error in the recently published tenth edition of *Recent Advances in Anaesthesia*, published by J. & A. Churchill Ltd., London.

On page 48, line three the dose of phenoperidine is given as 0.5 mg./kg. instead of 0.05 mg./kg. The publishers have already arranged for an erratum slip to be pasted into this page, but some copies had previously been put into circulation. I would be grateful if you would kindly print this letter so that readers of the book can make the necessary alteration if it has not already been done, and thus avoid any risk of possible overdosage.—I am, etc.,

London N.6.

C. LANGTON HEWER.

Crime and Sex Chromosome Anomalies

SIR,—Recent studies^{1,2} have shown a relatively high incidence of chromosome anomalies among mentally disordered patients, a large proportion of whom were mentally subnormal, requiring treatment under special security owing to dangerous violent or criminal propensities. It has been suggested that an association exists between the possession of an extra Y chromosome, increased stature, and a tendency to criminal behaviour.

We are therefore undertaking a chromosomal survey among prisoners received into H.M. Prison, Wandsworth. The two groups being examined are (a) consenting accessible prisoners of height 6 ft. (1.8 m.) or over and (b) consenting accessible randomly selected prisoners admitted during the same period.

Leucocytes were cultured from peripheral blood employing the method of Moorhead *et al.*³ Results so far obtained are as follows: (a) of 34 subjects examined 31 were normal, 2 were 47 XYY, and 1 47 XXY; (b) of 33 subjects 32

were normal and one a possible balanced translocation with 45 chromosomes (16/21-22?). In group (a) there were two subjects with very long Y chromosomes (defined as twice the length of the G group chromosomes). One of these was an XYY subject.

The numbers concerned are too small to allow statistical analysis, but enlargement of the present samples may enable us to examine a number of variables connected with sex chromosome anomalies.

J. Z. has been the recipient of a grant from the Mental Health Research Fund.

Major Accident Procedure

SIR,—Many of us will recall the tragedy of the 1957 Lewisham train crash, and the haphazard manner in which the various accident services operated. As a direct result of experience gained at that time, major accident procedures were developed covering the whole country. Recently we have experienced another train crash near by, at Hither Green, but on this occasion the accident services worked well, being highly organized in their operations.

As a consequence, the planners of major accident procedures are no doubt resting content, presuming that such efficiency would have pertained elsewhere. However, in my opinion the sole reason why efficiency prevailed the other week at Hither Green was due to the fact that the same teams of personnel were involved as in 1957, having resolved that they personally would never again provide an inefficient major accident service.

Outside the Lewisham area the plans for major accidents are undoubtedly highly organized, but I for one am sceptical that these are anything but paper plans. Having worked as a casualty officer in six hospitals in the North-east Metropolitan Region in the past few years, at only one have I been made aware of the existence of the major accident procedure. As one who is deeply interested in the provision of accident services, I hope that all concerned will review their plans following the Hither Green tragedy, and make certain that the personnel involved are kept fully informed.—I am, etc.,

London E.15.

CHRISTOPHER BOLT.

Computers in Medicine

SIR,—Do you think that our profession has seen what is in this Pandora's box (4 November, p. 250)? The lid is open and cannot be closed—but shall we be servants or masters of its contents?

Every technical advance of our era has, through our own folly, brought more harm than benefit. Need one give instances? The telephone has destroyed the privacy of thousands; the internal combustion engine the civilization of our cities; the television the freedom and originality of our minds; pharmaceutical advance has given us the practical certainty of world starvation; and nuclear fission the high probability of the destruction of life itself. It is a solemn warning we are generally afraid to heed.

There are ominous signs that the computer is already becoming an instrument of depersonalization and intimidation. It could be a source of new knowledge and power for the good of our strange race, but we shall have to rule it with a determination commensurate with its potentialities.—I am, etc.,

Exmouth, Devon.

RICHARD HARDY.

Doctors for Industry

SIR,—I would like to follow the lead given by Drs. G. A. Lawrenson and M. E. M. Herford (7 October, p. 52) in commenting on the leading article "Doctors for Industry" (16 September, p. 692).

As a doctor in medical charge of an Army training regiment over the past five and a half years, I have seen approximately 5,000 young men of 17 to 18 years of age coming into the Army after upwards of two years spent in mostly industrial occupations, and have carried out several brief examinations on the majority of them, which have been of great value in supervising their physical well-being and assessing their physique and state of nutrition.¹ All these have been young men without specific handicaps, and, as Dr. Herford comments, would be abandoned by the Factory Medical Inspectorate of the future as needing no medical care other than the treatment of illness, in spite of much poor but partly remediable physique on the one hand, and considerable obesity on the other.

I join him in challenging this proposed change, and am in agreement with his general conception of planning the medical care of the "whole man" during the vital youthful years in industry. In the Army we have to devote considerable attention to physical requirements in order to bring our recruits up to our own modest standards of physical efficiency and nutritional well-being, and, for the most part, among those who make the grade and stay with us, we succeed very well. In consequence, lack of stamina and many other accompaniments of poor physique are remedied, as well as obesity reduced, and in addition we see little of the problems of abnormal behaviour and aggressiveness which are characteristic of this age group today. Our regimen does seem to possess something helpful for growth into maturity which is lacking in much of what society today offers young people. We do in fact provide that "whole man" care which Dr. Herford advocates.

Judging from this experience it seems to me that a medical service to young people in industry must include among other things provision for a number of routine medical examinations designed to assess growth, physique, and nutrition, so that appropriate advice or treatment may be given. In putting forward this proposal I do not intend in the least to belittle other aspects of health which

CONSIDER NOW

summer-long protection against HAY FEVER with

D-VAC Pollens 3 dose course

regd.

D-VAC Pollens, Bencard emulsified 'depot' vaccine for 'classical' hay fever and pollen asthma, is the latest development in desensitising vaccines. The course of three carefully graded injections—fewer than for any other available—has been shown to be at least as effective as the much longer course with aqueous vaccine. Injection from a specially designed syringe ensures the controlled release of active emulsion through surrounding 'shield' emulsion. Local or systemic reactions are therefore rare provided that the recommended technique of administration is employed under antihistamine cover.

D-VAC Pollens is prepared from extracts of 12 varieties of common grass pollens (Bencard group B2), which are responsible for over 80% of cases of 'classical' hay fever and pollen asthma. Two alternative courses are available:

Primary Course: designed for patients who have not received pollen vaccine treatment in the last five years or whose seasonal symptoms are severe, and for children (aged 8-14 years).

Advanced Course: designed for patients aged 15 years and over who have had pollen vaccine treatment in the last five years and whose symptoms are not very severe.

(Patients suffering from atopic eczema should first be referred to an allergy clinic.)

The 3 injections are administered pre-seasonally at intervals of exactly 4 weeks, the first dose given in February or early March. Full technical details (administration, precautions, possible reactions, etc.) are supplied with each dose, or on request.

TO BE SURE

of obtaining D-VAC Pollens, it is advisable to prescribe and order **before 31st December**—quoting the course required (Primary or Advanced), the patient's name, and the date on which it is intended to administer the first dose: this date should fall **between 12th February and 9th March, 1968.**

Late orders will be met if possible up to 20th January, but in these cases first doses cannot be supplied for administration before 19th February.

The three doses of the course will be despatched separately at 4-week intervals to arrive in good time for administration, without need for further prescription or order.

(D-VAC Pollens is not available outside the U.K.)

Consultant Distinction Awards

SIR,—Dr. T. Manners (4 November, p. 298) highlights one of the greatest problems facing the hospital service today. The tendency of the present Review Body to extend the scope of the distinction award system inevitably means that it is regarded as part of the consultant's essential salary structure. This also means that the very substantial number of consultants who will never receive an award, many of whom have little or no private practice today, will, unless some considerable changes are made, remain with few exceptions the lowest paid of all senior doctors both in the hospital service and in general practice.

This state of affairs creates two fundamental problems. It ensures that the consultant who works hard to provide the best possible National Health service to his patients goes unrewarded, whereas his colleague who works less hard inevitably develops waiting-lists, and so patients, in desperation, begin to come to him privately. This in turn leads to less time being available for hospital work and more work falling on the shoulders of junior staff. Thus does the reward increase as the contribution to the National Health Service decreases. The second great problem concerns the integration of general practitioners into the hospital service. As one who for years has supported this policy in the form of clinical assistantships and the smaller cottage-type hospital I was delighted to see that the Scottish Working Party¹ advocates its extension. They foresee that the disparity between the rewards of general practice and the basic salaries of the hospital service will prevent many general practitioners from taking on hospital commitments. On the other hand, if the medical assistant salary is increased to the point where it competes with general practice, not only the registrar but also the consultant will find that his session earns him less than his assistant.

The distinction awards can never overcome these fundamental problems, and unless the Government and Review Body realize their importance and put forward definite proposals for surmounting them the next 15 years may be remembered as a period of rising waiting-lists and a constant move towards private practice, to the lasting detriment of a hospital service the great achievement of which has been to provide for the less fortunate members of our society a standard of medical care unequalled throughout the world. No Government, and least of all a

Socialist Government, should allow anything to imperil it.—I am, etc.,

Princess Margaret Hospital, K. D. CROW.
Swindon, Wilts.

Countersigning of Forms

SIR,—After a long and distressing illness a patient of mine died last month of carcinoma of the bronchus. The appropriate form for a night visit (E.C. 81a) was sent to me by the Southern Relief Service, having been signed by their doctor but not by the patient's widow. I cannot bring myself to debase my profession by taking this form round to the house of my deceased patient at the time of his widow's grief. For this reason I am sending the form to the executive council in its present state.

I feel the larger issue of having similar forms countersigned at all is a source of deep concern and dissatisfaction to all members of the medical profession.—I am, etc.,

Wallington,
Surrey.

C. R. NUNAN.

Approval of Emergency Treatment Service

SIR,—Your correspondent Dr. A. Dowling (25 November, p. 490) attempts to defend the Emergency Treatment Service and suggests medico-political influences as the reason for its "non-starter" status in London.

I would like to question whether there is any real need of the service at all in a well-organized general-practitioner service. Surely in most towns (at least of the size where E.T.S. operates) it should be possible for doctors to organize themselves in efficient practices with four to five partners and thus ensure about one night on in four. Is that asking too much? And also are doctors really happy about State Registered Nurses answering the phone?

There is a lot of emotional talk about whole patient care and responsibility for one's patients, but if one of a group of general practitioners cannot be on call to deal with one of their patient's acute appendicitis, cardiac asthma, or simply answer a pertinent question are those doctors really providing a service in keeping with the tradition of good family doctoring? The answer is "no," and as soon as doctors do something about making their services efficient the sooner will schemes such as E.T.S. wither and patients will be much more satisfied.—I am, etc.,

London S.W.17.

PETER FITT.

Educating the Public

SIR,—The Government, we are informed,¹ has agreed to continue with the "education of the public in the use of doctors' services," for which we must be grateful. However, I am sure that this has been used as an argument between our negotiators and the Ministry.

Surely, if they really wished to improve the lot of individual doctors, it would be much more efficient if they set aside a proportion of the sum they are now making available for leaflets, posters, and news-flashes for a grant to individual practitioners, who could then compose their own "notes for the guidance of patients," which, if approved, could be included with the medical card sent out by the executive councils. This is a practice which has been carried out for many years by our own very helpful council and caters for the vast variety between different practices.—I am, etc.,

Cambridge.

GORDON SIMPSON.

Simplifying Filing

SIR,—The world is getting rather full of paper and other records, such as radiographs. Especially in medical establishments there would seem to be a lack of system with regard to what to keep and what to throw away. As far as my experience reaches there is in practice a rather arbitrary custom of deciding that after x years documents must be discarded to make room for more recent ones. At this stage it is impracticable to sort them out as to their relative values, so they all go out together.

The following is a suggestion to allow documents to be marked when they are being dealt with in the first place in such a way that a clerk can go through them periodically and throw out those which have been marked with the relative lack of priority. As far as medical documents are concerned they seem to me to have four more or less separate values: Clinical "C"; Research "R"; Administrative "A"; and Litigious "L." The periods I suggest as being useful and not too numerous are 1, 3, 10, 30, and 100 years, combining these in a diagram or table:

	Yrs	1	3	10	30	100
Date	C					
	R					
	A					
	L					

If this diagram is stamped on relevant documents it is easy when reporting on or filing the document to tick the relevant "boxes" to indicate conspicuously that a valuable report or radiograph should not be thrown away before a less valuable one. Presumably the "C" and "R" lines would be the responsibility of the consultant and the "A" and "L" lines would be the responsibility of the hospital secretary. And the whole would give a clear indication for discarding, retaining, or reassessing.

At this stage I will not enter into a lengthy discussion; that will be more fitting when the C.R.A.L. has been tried out in practice. This is merely a preliminary notice.—I am, etc.,

Halsstead, Essex.

W. A. L. COLLIER.

Obituary Notices

M. L. HINE, M.D., F.R.C.S.

Mr. M. L. Hine, consulting ophthalmic surgeon to Charing Cross Hospital and the Royal Westminster Ophthalmic Hospital, London, died on 2 December. He was 84.

Montague Leonard Hine, son of a doctor, was born at Leytonstone, Essex, on 24 January 1883, and received his early education at Rydal Mount, Colwyn Bay. He had a

(Elliott & Fry)

distinguished academic career, obtaining an entrance scholarship to the Middlesex Hospital in 1900, and first and second year exhibitions. He qualified with the Conjoint diploma in 1905, and a year later he graduated M.B., B.S. with honours and distinction in medicine, and was designated Broderip scholar. After early resident appointments at the Middlesex Hospital he proceeded M.D. in 1907, and took the F.R.C.S. the following year. In 1909 he went to Singapore and to the Cocos Islands as medical officer to the Eastern Extension Cable Company. After returning to England he held appointments as clinical assistant and registrar at the Royal Westminster Ophthalmic Hospital (now Moorfields Eye Hospital, High Holborn) from 1912 to 1914, becoming surgeon in 1915, and dean of the medical school from 1920 to 1946.

During the first world war he served as eye specialist with the R.A.M.C. in France. After demobilization with the rank of captain he was appointed ophthalmic surgeon to the Miller General Hospital in 1919, a post he held until 1934. He was also ophthalmic specialist to the Ministry of Pensions from 1919 to 1928. In 1934 he was appointed ophthalmic surgeon to Charing Cross Hospital. He was a past president of the ophthalmic section of the Royal Society of Medicine, and editor of the 7th to 10th editions of May and Worth's *Diseases of the Eye*.

He married in 1924 Jennette M. Robertson, and they had a son and a daughter.

T. K. L. writes: With the death of Mr. Montague Hine ophthalmology has lost one of the last of the old school of ophthalmic surgeons who did an enormous amount of work in a relatively short space of time, and yet performed it with the greatest care and attention and with the maximum satisfaction to his patients. Punctually on Monday and Thursday afternoons he walked into the outpatient department ready for the fray, and worked hard seeing all the new patients at his clinic and at the same time teaching all the students around him. His house-surgeons would never dream of being a minute late. It was a pleasure to work for him, and he had at his command a large number of faithful

clinical assistants who had served him for many years. It was in the operating theatre where we house-surgeons found him of the greatest help, for he among all the honorary staff was by far the most generous in delegating operations to us. He would go to endless trouble in helping us with difficult cases, and his practical expertise was remarkable. Not that he was an exceptionally spectacular surgeon to watch, but his clinical judgement was first-rate and his technique always safe. There must be many generations of house-surgeons at the Royal Westminster Ophthalmic Hospital who have cause to be grateful to him for his valuable teaching. He was always keen to undertake new methods of treatment, and throughout life remained a keen student himself eager to try out new ideas. He was one of the first surgeons in the hospital to undertake operations on the vertical muscles in certain cases of squint.

His patients realized at once that they were in safe hands with Monty Hine. Indeed he never failed to listen to all their troubles, and to reassure them. He was as good a physician as he was a surgeon, but above all it is his excellence as a teacher by which he will long be remembered.

D. S. TORRENS, M.A., M.B., B.CH. B.A.O.

Professor D. S. Torrens, professor of physiology and former dean of the medical school at Trinity College, Dublin University, died on 24 November in a Dublin nursing-home. He was 70.

David Smyth Torrens was born in County Londonderry on 10 September 1897. He went to Trinity College as a demonstrator in physiology in 1922 from the zoology department of the Institute of Science in Dublin. He later became assistant to the professor, and during this time he decided to study medicine at Trinity College, and graduated M.B., B.Ch., B.A.O. in 1934. In 1936, on the death of Professor Pringle, he was elected to the chair of physiology and to the King's professorship of the Institutes of Medicine. He was dean of the Trinity College medical school from 1950 to 1959, and was vice-dean from 1959 to his retirement in September of this year. During his time as dean of the medical school he was a member of the General Medical Council.

David Torrens had a natural instinct for teaching and devoted his college life wholeheartedly to the interests of the students. He combined this with an inborn aptitude for physiology, and more especially histology, fascinating an audience of staff and students alike with his observations on the most simple histological specimen. For many years he was the unofficial College doctor, and—even after the inauguration of the College health service—staff and students frequently confronted him with their problems, worries, and diseases. His rooms in College were his home

for forty years and his address was familiar to many thousands of graduates, not only medical, who are now scattered throughout the world. It was in his rooms that Davy could be found at all hours of the day and night entertaining students past and present. Breakfast was served to those who came directly from the mail boat, tea was served at any hour, and late-night visitors were often treated to fried egg and bacon from midnight onwards. Nothing was too much trouble for him. No one will ever know how much money he lent to those in difficulties. Shortly before his retirement his friends were given the unique opportunity of repaying in some small way the debt they owed him. Contributions poured in from all corners of the world and to him his presentation fund became embarrassingly large. In a gesture which was typical of him he insisted on returning the largest contribution, saying that the sender's need was greater than his.

With typical modesty he never spoke of his attainments in the field of horology, yet he had pursued his interest in clocks and watches since the age of 10, and had become known among horologists as a leading authority in this specialty. His eminence in horology was recognized at a ceremony in London as recently as last September, when he was made an honorary freeman of the Worshipful Company of Clockmakers. During his lifetime he amassed a vast quantity of clockmakers' tools, and here again was evidence of his generosity, for he made a habit of purchasing the property of clockmakers after their death as a means of financially assisting the next of kin.

To those who did not know of his extreme generosity and his infinite ability to assist those in need, his popularity was difficult to understand. His manner was often sharp to the point of rudeness, and he was not a conversationalist, always preferring to listen rather than to talk. Even among his closest friends he rarely, if ever, talked about himself. No one will ever know the extent of his achievements, but one thing is certain—that he gave far, far more to this world than he ever attempted to take from it.—C. C. C. O'M.

CASIMIR FUNK, PH.D.

Dr. Casimir Funk, a pioneer in vitamin research, died in Albany, New York, on November 20, at the age of 83.

Casimir Funk was born in Warsaw on 23 February 1884, but when 16 years old went to Switzerland for his education, first at Geneva and later at the University of Berne. Trained as a chemist he gained his Ph.D. in 1904, when still only 20. He then moved to the Pasteur Institute in Paris to study under Bertrand, and two years later to the University of Berlin, where he worked under the guidance of Fischer and Aberhalden. Apart from a year at the Municipal Hospital in Wiesbaden, where he first became interested in the science of nutrition, he remained in Berlin until 1910, when he came to London.

In 1911 he entered the Lister Institute for research on experimental beriberi, and remained there for five years. After a period at the Cancer Hospital Research Institute he left in 1915 for the U.S.A., where he worked in various laboratories and attacked problems such as the synthesis of adrenaline and the extraction of vitamins from fish-liver oils on a commercial scale. In 1923 he returned to Warsaw to organize the department of biochemistry of the State School of Hygiene. 1928 found him in Paris, working mainly on sex hormones, and he remained there until 1939, when he returned to settle permanently in New York. In 1947 he organized the Funk Foundation for Medical Research, and became its president. The rest of his life was devoted mainly to cancer research.

Undoubtedly it is the word "vitamin" by which Funk will be remembered. In his attempts to isolate the factor in rice polishings that can prevent human beriberi and avian polyneuritis, which actually resulted only in the production of crude concentrates, Funk correctly concluded that the elusive substance was an organic base. It was obviously essential for life, so "vitamine"—shortened from "vital amine"—seemed a suitable name. Moreover other diseases were recognized as being due to dietary deficiencies, and it was concluded that they might be due to lack of other vitamins. Thus in June 1912, according to the *Journal of State Medicine*, he grouped together "beriberi, polyneuritis in birds, epidemic dropsy, scurvy, experimental scurvy in animals, infantile scurvy, ship beriberi, and pellagra" as deficiency diseases, and speculated that rickets could be added to the list. He was not alone, of course, in propounding this theory. He was, indeed, passed over when many years later a Nobel award was shared between Hopkins, for his proof of the existence of "accessory food factors," and Eijkman, for his pioneer work on the relationship between human beriberi and avian polyneuritis.

Eventually, as the various "vitamines" were obtained in pure enough form to allow some knowledge of their chemistry, it became clear that they were widely different substances, and that some did not contain nitrogen. The final "e" was therefore dropped, to leave "vitamin," which has no chemical implications. Funk's inspired choice of a name has been of great service to biochemists and nutritionists in helping to correlate facts and theories in a specialized field. Even since the various vitamins have been isolated, chemically identified, and given chemical names it has remained a great convenience to class them together as vitamins—a group of biologically active substances.—T. M.

E. V. MCCOLLUM, PH.D., LL.D.

Professor E. V. McCollum, who died in Baltimore, Maryland, on 15 November, aged 88, was distinguished for a long career devoted to the science of nutrition. His early research on vitamins was about contemporary with Funk's work in this field, and it is melancholy, but convenient for paying tribute to their memories, that their deaths should have occurred so close together.

Elmer Verner McCollum was born on a farm in Kansas on 3 March 1879, and was educated at the University of Kansas and at Yale, where he took his Ph.D. In 1907 he

became an instructor in agricultural biochemistry in Wisconsin University, where he stayed to become an associate professor, and eventually full professor. In 1917 he left Wisconsin to become professor of biochemistry in the School of Hygiene and Public Health in the Johns Hopkins University, Baltimore, a post from which he retired in 1946. He remained in Baltimore, and retained his interest in nutrition, for the rest of his life.

McCollum's discovery of vitamin A, on which his main claim to fame might be based, was made while he was in Wisconsin. In 1913, with M. Davis, he confirmed the finding of Hopkins and others that rats could not live for long upon a diet made from purified protein, carbohydrate, and fat. Butter and egg yolk contained a factor which would allow survival and growth if given as small supplements to this purified diet, but olive oil and lard were inactive. This substance was named by McCollum "fat-soluble A." Two years later another substance which promoted growth in rats was detected in aqueous extracts of wheat germ and egg yolk. It was named "water-soluble B," and was identified with Funk's antipolyneuritis factor. Before long Funk's and McCollum's systems of nomenclature were combined, and the recognition of vitamins A and B opened up a long and fruitful period of research throughout the world. As a further important contribution, made after going to Baltimore, McCollum in 1922 differentiated clearly between vitamins A and D. Hopkins had shown that when heated fat is aerated vitamin A is destroyed. McCollum, Simmonds, Becker, and Shipley treated cod-liver oil in this way, and found that vitamin A was lost without a corresponding loss of the antirachitic value of the oil.

During his long career McCollum also became interested in mineral metabolism. After his finding that manganese is necessary for lactation in rats, headlines appeared in the popular press to the effect that "manganese is mother love." He wrote two excellent books—*A Newer Knowledge of Nutrition* (with Nina Simmonds) in 1918, which ran through several editions, and *A History of Nutrition* in 1957. In personality he was friendly, erudite, and approachable. His unofficial title in America, "the father of nutrition," was well deserved, as also were his foreign Fellowship of the Royal Society and his honorary membership of the (British) Nutrition Society. The passing of this "grand old man" will be much regretted by all his British friends.—T. M.

S. H. WARREN, M.R.C.S., L.R.C.P. D.P.H.

Dr. S. H. Warren, a former director of the Central Public Health Laboratory at Newcastle upon Tyne, died on 31 October. He was 85.

Stanley Herbert Warren was born on 16 January 1882, and received his medical education at St. Mary's Hospital and University College Hospital, London, qualifying with the Conjoint diploma in 1905. He was trained in the Bacteriological Laboratory at St. Mary's Hospital under the late Sir Almroth Wright, and had been demonstrator in bacteriology at University College Hospital Medical School for two years before taking up an appoint-

ment as resident pathologist at the Royal Sussex County Hospital, Brighton. He took the D.P.H. in 1908, and was later awarded a Graham scholarship at University College Hospital which enabled him to undertake further research into pathology and bacteriology. The outbreak of the first world war ended his tenure of the scholarship and he joined the R.A.M.C. After demobilization with the rank of captain he went to Newcastle to join the staff of the department of bacteriology of what was then the University of Durham College of Medicine, and on Tyneside he spent the remaining 40 years and more of his life. The work of the department included not only teaching and research but also the provision of bacteriological services for local authorities and others in north-east England, and he became chiefly engaged in the latter branch of the departmental activities. Administrative rearrangements a few years later resulted in the services for the local authorities being made the responsibility of an independent Public Health Laboratory, of which he was appointed director; and, apart from a two years' absence while in charge of a wartime emergency laboratory, he was director of the Public Health Laboratory for nearly 20 years. He retired shortly after its merging in the national Public Health Laboratory Service.

E. M. D. writes: Warren was an able bacteriologist, of consummate technical skill, and experienced in laboratory organization. He supervised personally all the work of his laboratory to ensure the high standard of efficiency he demanded. He had to contend for very many years with the grievous handicap of increasing deafness, a disability which made conversation with him difficult, and he suffered much in consequence. Of a sensitive disposition, he came to be diffident about joining in company and to limit social contacts to companionship with some friendly colleague in whose presence he could relax and feel less isolated. He married in 1941, and from then until his death the relatively lonely life which had so long been his became happily transformed. He is survived by his widow and two sons.

A. WILKIE, M.B., CH.B.

Dr. A. Wilkie, a general practitioner in Droylsden, Lancashire, died in hospital on 14 November after a short illness. He was 61.

Alfred Wilkie was born on 25 March 1906, and received his medical education at Aberdeen University, graduating M.B., Ch.B. in 1928. After early appointments at Hull Royal Infirmary and the East Suffolk and Ipswich Hospital he became assistant medical officer at Heatherwood Hospital, Ascot. In 1939 he settled in general practice in Droylsden, and in his quiet unassuming manner quickly endeared himself to the people of the area. He took an active part in local affairs, and in 1962 became chairman of the Ashton-under-Lyne Division of the British Medical Association. In the same year he became the senior partner of the large practice which he had helped to build. He was severely ill in 1958, but made a good recovery and continued to lead an active life and practice.

His wife died in 1954 after a long illness, and they had no children. His loss is keenly felt by his colleagues.—A. M. G.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of deaths from influenza and cases of whooping-cough in England and Wales.

Figures for 1967 are compared with the highest and lowest figures for each week in the previous years shown.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending 18 November (No. 46) and corresponding week 1966.

Figures of cases are for the countries shown and for Greater London. Figures of deaths and births are for the whole of England and Wales (London included), Greater London, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

PARLIAMENT

Questions in the Lords

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Treatment of Drug Addicts

LORD SANDFORD asked the Government on 28 November how many drug addicts had been seen at the treatment centres set up in connexion with the Dangerous Drugs Act; how many were receiving treatment at each centre; and what treatment was being given.

LORD KENNET stated that the most recent records of the treatment of heroin addiction by National Health Service hospitals related to the quarter ended 30 September, in which 173 persons were admitted as inpatients and 171 commenced outpatient treatment. At the end of September 64 inpatients and 167 outpatients were receiving treatment at 39 hospitals.

The forms of treatment, which varied widely and were determined by clinical judgement in individual cases, included psychotherapy with individual patients or in groups, physical methods of treatment such as drugs, occupational and industrial therapy, and social support. Attention was also given to patients' physical condition.

LORD SEGAL asked on 30 November what was the Government's estimate of the number of heroin addicts likely to be notified under the Dangerous Drugs Act, and when accurate statistics were likely to become available.

LORD STONHAM, Minister of State at the Home Office, told him that the number of

known addicts in 1966 was 899, but the Home Office could not firmly estimate the number that would be notified until the regulations requiring notification were in force, which it was hoped would be early next year.

He added in answer to Lord Segal that one of the regulations would require a doctor attending a person he thought or suspected to be addicted to any drugs to notify particulars to a central authority. The other regulation would restrict the prescribing of heroin and cocaine to addicts, and that regulation was being drafted.

LORD SEGAL, emphasizing the importance of research, asked if the notification forms could include additional information such as occupation, country of origin, whether the addicts were on sickness or unemployment benefit, and other details that might be of value.

LORD STONHAM explained that the forms which would be completed under the regulations would give all the information thought necessary. The central records were being transferred from the drugs branch of the Home Office to the statistical branch, which was better equipped to maintain them. Some of the items mentioned by Lord Segal might not be required, but the Home Office would look at all of them.

Abortion Act Registrations

LORD SEGAL, commenting on the number of applications from private nursing-homes for registration under the Abortion Act [it was 100 up to 24 November] suggested in the House of Lords on 30 November that, as the demand for abortion beds might greatly exceed the supply, unoccupied beds in maternity hospitals might be made available for emergency abortion cases when the Act came into operation.

LORD KENNET, speaking for the Government, promised to bring the suggestion to the attention of the Minister of Health.

VISCOUNT BARRINGTON inquired whether, if the number of applications was regarded as low, this might be due to the widespread opinion in the medical profession—particularly as reflected in the presidential address of the President of the Royal College of Obstetricians and Gynaecologists—that doctors did not yet know where they were in this matter.

LORD KENNET said he knew of no reason for disappointment about the number of applications that had been received.

LORD SILKIN suggested that as the Act did not come into operation until April it was rather early to be putting these questions and creating doubts.

LORD KENNET agreed, pointing out that the normal process of advertising for applications, considering them, and inspecting premises was now under way.

MEDICO-LEGAL

Blood Tests and Adultery

[FROM OUR LEGAL CORRESPONDENT]

Blood tests on a husband, wife, and child were the foundation for a finding of adultery made against the wife by Mr. Justice Rees in the High Court on 6 November (*The Times*, 7 November).

The parties were married on 21 November 1959. The wife had during the marriage persistently stayed out late despite the husband's complaints. At the relevant time the wife and husband were having regular intercourse. Though they were using contraceptive procedures, it was possible that the wife might have conceived a child by the husband. The parties separated on 14 January 1961, and the child was born on 17 June 1961.

In August 1961, for the purpose of magistrates' court proceedings, the husband's solicitors asked the wife whether she was willing to provide blood samples from herself and the child for comparison with a sample from her husband. She agreed.

Dr. Alan Grant, lecturer in forensic serological medicine at Guy's Hospital, took samples from the parties and the child on 26 August, and grouped them under a num-

ber of systems, including the Rhesus system. In the child's blood he found Willis C factor, which was absent from the blood of the husband and the wife. Further samples were taken on 11 June 1966, with the same result. No further information was obtained by applying to both the earlier and later samples further grouping systems which had become available since 1961.

Dr. Grant gave his opinion that, as there was no dispute that the child was the mother's, and as neither she nor her husband had Willis C factor, the husband could not be the father. This opinion was expressed to be subject to the biological possibility that the Willis C factor might have appeared in the child's blood as a result of a mutation. Dr. Grant said that it was plain from the structure of the blood groups that in the course of evolution mutations had occurred. For over 20 years he had been "feverishly searching for evidence of a mutation" and had found none. In giving evidence before the magistrates in 1962, Dr. Grant had assessed the chances of a mutation occurring at one chance in 50,000 generations. He

now revised that assessment to about one chance in 1,000,000 generations. There was even less chance that Willis C factor could be present in the blood of the husband and wife but be so suppressed as to be not apparent on examination.

Mr. Justice Rees accepted Dr. Grant's evidence and granted a decree nisi to the husband on the ground of his wife's adultery. He also made a declaration that this child was not the husband's. Since the result of the decree was to bastardize the child, the court demanded a high standard of proof of adultery before making the decree. The court required to be satisfied of adultery beyond all reasonable doubt.

The child was represented at the hearing by counsel instructed by the Official Solicitor. The questions whether or not the Official Solicitor should consent to the child's blood sample being taken, and whether the court had power to order the sample to be taken without consent, did not arise, presumably because the mother had already given consent in 1961. Judgement of the Court of Appeal in a case raising these questions is still awaited.¹

MEDICAL NEWS

Chancellor of Cambridge University

LORD ADRIAN, O.M., F.R.S., a former Vice-Chancellor of Cambridge University, has succeeded the late LORD TEDDER as Chancellor.

A Nobel Laureate in medicine, Lord Adrian was professor of physiology at Cambridge from 1937 to 1951. He then became Master of his old College, Trinity College, Cambridge, retiring in 1965. In 1954 he was President of the British Association while also

(Douglas Glas)

President of the Royal Society. The following year he was raised to the peerage. In 1958 the British Medical Association awarded him the Association's Gold Medal for Distinguished Merit in recognition of his services to medicine, particularly his research in the physiology of the nervous system.

Royal College of Physicians of Edinburgh

At the annual meeting of the Royal College of Physicians of Edinburgh on 30 November the following officer-bearers were elected: president, Dr. C. W. CLAYSON; vice-president, Dr. J. HALLIDAY CROOM; members of council, Professor R. H. GIRDWOOD, Dr. J. LAURIE, Dr. R. F. ROBERTSON, Professor J. W. CROFTON, and Dr. E. B. FRENCH.

Chair of Psychiatry at Oxford

The W. A. Handley Charity Trust is to give Oxford University £121,000 to endow a professorship of psychiatry.

The Nuffield Committee for the Advancement of Medicine at Oxford is to allocate £5,000 a year to support the chair. The Oxford Regional Hospital Board has offered the professor accommodation and facilities as well as an annual contribution, and the United Oxford Hospitals have offered consultant status and outpatient facilities.

Care of the Elderly

Opening the first purpose-built psycho-geriatric assessment unit in this country at Barncoose Hospital, Redruth, Cornwall, on 29 November, the MINISTER OF HEALTH said that geriatrics was being increasingly accepted as a rewarding career. The number of consultant geriatricians had risen from 115 in 1964 to 156 in 1966.

Combined Unit for Cardiac Surgery

A report prepared by a joint committee of the Royal Colleges of Physicians and Surgeons describes the requirements of a combined unit for medical and surgical care of heart disease at all ages. Such a unit, the report states, must have facilities for diagnosis, treatment, and research. Facilities for training should also be available. The unit should be sited in a general hospital and be linked to diagnostic, therapeutic, and research services in other branches of medicine and surgery. It should be flexible enough to allow for expansion. Other recommendations refer to size, staffing, and work load.

Appointment to Professorship

Dr. J. H. GREEN, reader in physiology at the Middlesex Hospital Medical School, has had the title of professor of physiology conferred on him. He is 48. Dr. Green was educated at Cambridge, where he graduated M.B., B.Chir., and at the Middlesex Hospital Medical School. He has been a member of the physiology department at the school since 1951 and was appointed reader in 1960. He holds the Ph.D. (Lond.).

Dr. Green's main research interests lie in the regulation of blood pressure by baroreceptors. His other interests include the use of closed-circuit television and video-tape recording as teaching adjuncts. He is the author of the textbook *An Introduction to Human Physiology*, published in 1963.

Nurse Education and Training

The Ministry of Health is financing the establishment of a research unit at the offices of the General Nursing Council for a period, in the first place, of five years. Besides carrying out research into nurse education, the unit will co-ordinate work on experimental schemes of training. It will be staffed by a research officer (a new post) and two assistants. Miss G. E. WATTS, chairman of the council, is chairman of the joint steering committee. The unit is expected to start work early in 1968.

Flats for Married Medical Staff

Supported by a grant from King Edward's Hospital Fund, the Bromley Group Hospital Management Committee has completed a two-storey building in the grounds of Farnborough Hospital, Kent, to provide accommodation for junior medical staff. The building comprises three one-bedroom and two two-bedroom flats, each with fitted kitchen, dining-room/lounge, and bathroom. All the flats are centrally heated. The building, furnishings, and equipment have cost approximately £22,000.

Protection Against Ionizing Radiations

Proposed regulations for the protection of workers against ionizing radiations were published by the Ministry of Labour last week. They include provision for radiological and medical supervision. The employment of a person under 18 on work that requires him to be designated as a classified worker is prohibited. Any objection to the draft regulations, which are complementary to the regulations of 1961, must be sent to the Secretary, Ministry of Labour, Baynards House, 1 Chepstow Place, London W.2, by 29 December. (The Ionizing Radiations (Unsealed Radioactive Substances) Regulations. H.M.S.O., 2s. 9d. net.)

Royal Society

At the anniversary meeting of the Royal Society on 30 November Professor P. M. S. BLACKETT, O.M., F.R.S., was re-elected President of the Society. Among Fellows

newly elected to the Society's Council are Dr. J. H. HUMPHREY, head of the division of immunology and deputy director, National Institute for Medical Research, and Professor W. D. M. PATON, professor of pharmacology at Oxford University.

Journal of Medical Microbiology

This new journal, which is expected to appear in August next year, is to be established as an official publication of the Pathological Society. It proposes to publish papers on all aspects of microbiology that apply to human and veterinary medicine.

British Council

Strengthening professional contacts between Britain and other countries was an important part of the work of the British Council in 1966-7. More than 700 specialist and advisory tours were carried out under its auspices, about half being concerned with science, medicine, technology, and agriculture. During the year the Council assisted some 12,000 overseas visitors to Britain, the highest number recorded.

People in the News

► Dr. MARY D. SHERIDAN has had the Honorary Fellowship of the Society of Medical Officers of Health conferred on her.

► Dr. BERYL CORNER is undertaking post-graduate teaching courses in neonatal medicine in medical schools in India under the auspices of the World Health Organization.

News in Brief

The National Cervical Cancer Prevention Campaign has changed its name to the Women's National Cancer Control Campaign.

Grants and Awards

The Medical Research Council has made a grant of £12,663 to Professor S. D. M. COURT, department of child health, and Dr. P. S. GARDNER, department of virology, University of Newcastle upon Tyne, to aid the continuation of studies of acute respiratory infection in children jointly undertaken by the two departments.

Coming Events

Postgraduate Medicine, 1967 (T.V. Programme).—"Puberty," Scottish Television, 11 December (11.50 p.m.), repeat 13 December (1.10 p.m.).

Royal Society of Medicine.—Holiday lectures for young people (13 to 19 years), 28-29 December and 3 January. Tickets (free) in advance. Details from Assistant Secretary, R.S.M., 1 Wimpole Street, London W.1.

British Medical Association.—Conference, "Educational Technology for Continuing Medical Education," 3-5 January, University of Sussex. Fee, including meals, 10 guineas (resident), 8 guineas (non-resident). Applications to Secretary, British Medical Association, Tavistock Square, London W.C.1.

Information and Library Services for Biomedical Engineering.—Conference, organized jointly by Biological and Engineering Groups of A.S.L.I.B., Biological Engineering Society and Hospital Physicists Association,

5 January, University College, London W.C.1. Fee £2. Details from Mr. B. R. STYLES, Technical Librarian, Ministry of Public Building and Works, Chessington, Surrey.

Association of Head and Neck Oncologists of Great Britain.—Symposium, "Tumours Involving the Lower Jaw," 12 January, 10.30 a.m., Chester Beatty Research Institute, Fulham Road, London S.W.3. Applications to Mr. R. W. RAVEN, Department of Surgery, Royal Marsden Hospital, Fulham Road, London S.W.3.

Association of Physicians of India.—Joint annual conference, 23–27 January, Cuttack. Details from Dr. B. B. TRIPATHY, S.C.B. Medical College, Cuttack, Orissa, India.

Central Council for Health Education.—Annual conference, "Dependence on Drugs and Alcohol," 25 January, St. Pancras Assembly Rooms, Town Hall, Euston Road, London N.W.1. The conference fee is £1 ls. and applications should be made to the Medical Director, C.C.H.E., Tavistock House North, Tavistock Square, London W.C.1.

Institute of Religion and Medicine.—Panel discussion, "Who Tells the Patient What?" 25 January, 2.30 p.m., Friends' House, Euston Road, London N.W.1.

Royal Eye Hospital.—Refresher course for consultant ophthalmologists, 19–23 February 1968. Applications should be made to Professor D. HILL, Courage Laboratory, Royal Eye Hospital, St. George's Circus, London S.E.1.

Central Council for Health Education.—Seminar for medical officers of health, "Family Life Education," 26–28 February 1968, Conference Centre, 70 Brompton Road, London S.W.3. Details from Medical Director, C.C.H.E., Tavistock House North, Tavistock Square, London W.C.1.

2nd International Congress of Lymphology. 15–20 March, Miami, Florida, U.S.A. Details from International Society of Lymphology, Central Office, P.O. Box 128, 8028 Zurich, Switzerland.

Week-end Refresher Course for General Practitioners.—Obstetrics, 23–24 March,

Postgraduate Medical Centre, Royal Victoria Hospital, Boscombe, Bournemouth. Details from Mr. S. LUBERT, M.R.C.O.G., at the hospital.

British Occupational Hygiene Society and North Staffordshire Medical Institute.—International symposium, "Health Conditions in the Ceramic Industry," 27–29 March 1968, North Staffordshire Medical Institute, Stoke-on-Trent.

Cambridge University Institute of Criminology.—Postgraduate course in criminology 1968–9. Applications by 31 March to Institute of Criminology or to Secretary, Board of Graduate Studies, Mill Lane, Cambridge.

Association of Surgeons of Great Britain and Ireland.—Annual meeting, 4–6 April, London.

European Association of Radiology.—Symposium Ossium, 4–6 April 1968, London. Details from Dr. J. S. MACDONALD, Secretary-General, Symposium Ossium, 156 Lambeth Road, London S.E.1.

Ophthalmological Society of the United Kingdom.—Annual Congress, 1968, 17–19 April, New Arts Building, University College of South Wales and Monmouthshire, Cardiff.

M.R.C. Mineral Metabolism Research Unit in association with Department of Urology, Leeds General Infirmary.—International symposium on renal stone research, 17–20 April 1968, Leeds. Details from Dr. B. E. C. NORDIN, General Infirmary, Leeds.

Third International Meeting of Endocrinology.—"Physiopathology of Adipose Tissue," 9–12 May 1968, Marseilles. Details from Secretariat, Hôpital de la Conception, 144 Rue Saint-Pierre, Marseilles 5.

Australian College of General Practitioners.—Fourth general practitioners' convention, 17–23 May 1969, Brisbane. Details from Honorary Secretary, P.O. Box 1498 V, Brisbane, Q.4001.

World Congress on Fertility and Sterility.—Sponsored by International Fertility Association, 20–27 May 1968, Tel-Aviv, Israel.

Details from Dr. N. SOFERMAN, P.O. Box 26102, Tel-Aviv.

International Association for Accident and Traffic Medicine.—Congress on motor-vehicle and aeroplane accidents, 29 May to 3 June 1969, New York City. Details from I.A.A.T.M., 520 First Avenue, New York, N.Y. 10016.

Societies and Lectures

For attending lectures marked ● a fee is charged or a ticket is required. Applications should be made first to the institution concerned.

Sunday, 10 December

BRITISH FELLOWSHIP OF THE ISRAEL MEDICAL ASSOCIATION.—At Hampstead Synagogue, 1 Dennington Park Road, London N.W.6, 3 p.m., Miss Ruth Aliav: Never the Last Road.●

Monday, 11 December

CHELMSFORD MEDICAL EDUCATION AND RESEARCH TRUST.—At Chelmsford Medical Academic Unit, London Road (grounds of Chelmsford and Essex Hospital), 5.30 p.m., clinical meeting.
HUNTERIAN SOCIETY.—At Talbot Restaurant, London Wall, 7 p.m., Professor E. B. Chain, F.R.S., Dr. F. Wrigley: The Birth of a Drug
INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY.—5.30 p.m., combined staff consultation clinical meeting.
KINGSTON-UPON-THAMES MEDICAL CENTRE.—5.15 p.m., Dr. S. D. Lawler: Chromosomes and Leukemia; 6.30 p.m., Dr. D. Robertson-Smith: Nuclear Sexing ●
ROYAL POSTGRADUATE MEDICAL SCHOOL.—4 p.m., lecture by Professor D. L. Mollin.
SCOTTISH TELEVISION LTD.—11.45 p.m., Puberty. (Sponsored by Glasgow Postgraduate Medical Board.)

Tuesday, 12 December

ROYAL POSTGRADUATE MEDICAL SCHOOL.—4 p.m., Professor R. B. Woburn: Adrenal Tumours.
ROYAL SOCIETY OF HEALTH.—At Caxton Hall, London S.W.6, 6 p.m., Professor R. F. L. Logan: The Role of the Hospitals in Community Health Care Today and Tomorrow.
TUNBRIDGE WELLS POSTGRADUATE CENTRE.—At Kent and Sussex Hospital, 8.30 p.m., Mr. R. Campbell Connolly: Cerebrovascular Catastrophes.
WESTMINSTER MEDICAL SCHOOL.—At Keene Lecture Theatre, 6.45 p.m., Professor G. S. W. Organe: Anaesthesia in Russia, 1967.
WEXHAM PARK HOSPITAL, SLOUGH.—At Lecture Room, School of Nursing, 8.45 p.m., Mr. P. French: Anterior Fusion in Cervical Spondylosis.

Wednesday, 13 December

B.B.C. 1 TELEVISION—11 p.m. (approx.), Medicine Today: Parkinsonism. (Sponsored by A.S.M.E.)
CHILMSFORD MEDICAL EDUCATION AND RESEARCH TRUST.—At Chelmsford Medical Academic Unit, London Road (grounds of Chelmsford and Essex Hospital), 12 noon, surgical meeting.
INSTITUTE OF CHILD HEALTH.—At Kennedy Lecture Theatre, 5.30 p.m., Professor J. J. van der Werff ten Bosch (Rotterdam): Effects of Growth-promoting Substances in Man.
INSTITUTE OF UROLOGY.—5 p.m., Dr. G. A. Rose: Calcium and the Kidney
KENNEDY INSTITUTE OF RHEUMATOLOGY.—At rear of West London Hospital, 5 p.m., Professor M. J. H. Smith: Metabolic Actions of Aspirin
MANCHESTER MEDICAL SOCIETY. SECTION OF PATHOLOGY.—At Large Anatomy Theatre, Manchester University Medical School 5 p.m., Dr. G. Taylor: Comparative Immunology.
ROYAL COLLEGE OF OBSTETRICIANS AND GYNARCOLOGISTS.—5.30 p.m., postgraduate Museum demonstration by Dr. W. B. Robertson: Uterine Fibroids
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Bradshaw lecture by Professor R. Milnes Walker: Cancer in South-west England
ROYAL FREE HOSPITAL.—5.15 p.m., Dr. M. A. Epstein: Cellular Structure and Function.
ROYAL POSTGRADUATE MEDICAL SCHOOL.—2 p.m. pathology guest lecture.
SCOTTISH TELEVISION LTD.—1 p.m., Puberty. (Sponsored by Glasgow Postgraduate Medical Board.)
STOKES MANDEVILLE HOSPITAL.—6 p.m., rag class by Dr. W. Stokes

Thursday, 14 December

BROOK GENERAL HOSPITAL.—2 p.m., cardiology extended course by Dr. R. Hartley, Dr. M. Zoob.
HONYMAN GILLESPIE LECTURE.—At Surgery Lecture Theatre, Edinburgh Royal Infirmary, 5 p.m., Dr.

New Issues of Specialist Journals

Obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

BRITISH JOURNAL OF OPHTHALMOLOGY

Contents of the December issue are as follows:

Haemorrhological Factors in the Development of Diabetic Microangiopathy. Jörn Ditzel.
Amblyopia Therapy: Results at the Giessen Clinic. J. T. Flynn and B. Verecken
Study of Late Phase Fluorescence in the Rabbit Fundus. A. W. Sollom and I. A. R. Brown.
Histological Study of Late Phase Fluorescence in the Rabbit Fundus. A. W. Sollom and I. A. R. Brown.
Misinterpretation of Sphenoidal Ridge Meningiomas. Aly Mortada
Posterior Subcapsular Cataracts and Macular Lesions after Long-term Corticotrophin Therapy. J. Williamson and T. G. Dulakos.
Corneal Hypersensitivity to Herpes Simplex. J. S. Swyers, R. N. Lausch, and H. E. Kaufman
Cytological Diagnosis of Phacolytic Glaucoma utilizing Millipore Filtration of the Aqueous. Morton F. Goldberg.
Ocular Manifestations of Vitamin A Deficiency. G. Venkataswamy.
Plastic Dermoid Cyst. B. Shukla and S. P. Srivastava
Ophthalmological Synopses. Book Review. Notes. Index, 1967.

Volume 51, No. 12. Yearly subscription (12 numbers) inland £8 8s., overseas £9. With *Ophthalmic Literature* and Index (7 numbers) inland £15, overseas £16.

Universities and Colleges

CAMBRIDGE

Sc.D.—G. A. Gresham, M.D.
Ph.D.—R. M. Clarke, M.B.
M.B.—C. J. G. Sutton, J. P. Dymond.

ABERDEEN

Appointments.—Dr. C. C. Bird (lecturer, Department of Pathology); Dr. J. E. Leng (terminable lecturer, Department of Child Health); Dr. Pierre Diomi (terminable lecturer, Department of Surgery); Dr. Audrey Sutherland (research fellow, Department of Social Medicine).

EDINBURGH

Appointment.—Dr. R. C. B. Aitken (senior lectureship, Department of Psychiatry).

LONDON

The title of reader in pathology in relation to oral disease has been conferred on Mr. T. Lehner in respect of his post at Guy's Hospital Medical School.

M.D.—Sylvia W. Davies.

Ph.D.—*In the Faculty of Medicine:* R. W. Daisley, M. M. A. Hassan, D. S. Hewick, S. A. Malcolm, E. J. Triggs, A. A. El-B. M. Wahbi, Dorothy G. T. Wells, R. M. Greenwood, S. I. Mekky, D. S. Pepper, J. R. Walton, R. St. C. Gaskin, E. M. Hawes, C. H. R. Palmer, R. H. Poyser, D. C. Thurlay, M. E. West, A. J. Bowdler, D. K. Luscombe.

Watson, P. E. Watts, Judith A. W. Webb, M. Webber, Caroline R. Weinberg, W. H. Weston-Davies, J. Wezelman, P. D. Whiteman, Carol M. E. Williams, E. Williams, J. L. Williams, Melanie Williams, W. R. Williams, P. D. Wimberley, Rosemary J. W. Winteringham, P. M. Wood, Jean M. Worms, J. W. Wright.

¹With honours. ²Distinguished in pathology. ³Distinguished in medicine. ⁴Distinguished in applied pharmacology and therapeutics. ⁵Distinguished in surgery. ⁶Distinguished in obstetrics and gynaecology.

The following candidates at the Institute of Psychiatry have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN PSYCHOLOGICAL MEDICINE.—*Part II:* J. R. W. Christie Brown, M. R. Eastwood, R. Gardner, G. T. Hollingworth, D. L. Julier, J. P. Leff, P. J. Noble, J. R. Pedder, J. Steiner, T. G. Tennent, J. P. Watson. *Part I:* M. J. Kelleher, A. Maiden, E. Tan.

MANCHESTER

Appointments.—Dr. M. R. Alderson, Dr. D. H. Vaughan (senior lecturers, social and preventive medicine); Dr. J. A. H. Nicholson (assistant lecturer, pathology); Dr. T. A. Cook (assistant lecturer, neuropathology).

WALES

WELSH NATIONAL SCHOOL OF MEDICINE

M.B., B.Ch.—K. Bartlett, J. M. Hussein, T. S. Loh, Esther I. K. Morgan, K. K. Ong, M. A. A. Oshodi, C. E. Rees, F. J. Shaw, N. G. Weinstock.

BIRMINGHAM

Appointment.—Dr. D. I. Rushton (lecturer, Department of Pathology).

LIVERPOOL

Appointment.—Mr. T. I. Baraket (research assistant in anatomy).

BRISTOL

Appointments.—Dr. K. D. Bhoola (senior lecturer in pharmacology); Dr. P. J. Curtis, Dr. R. A. Nicholson, Dr. O. B. Williams (demonstrators in anatomy); Dr. R. J. Harvey (lecturer in physiology); Dr. E. H. Mackay (demonstrator in pathology); Dr. E. S. Meek (lecturer in virology within the Department of Bacteriology); Mr. N. J. Moule (lecturer in radiodiagnosis); Dr. M. J. Purves (research fellow in physiology); Dr. J. A. O. Russell (lecturer in mental health (child psychiatry)); Dr. S. K. Mitra (research assistant in surgery).

ROYAL COLLEGE OF SURGEONS IN IRELAND

On 1 December the fellowship in surgery of the College was conferred on the following:

P. F. Bates, K. Haider, B. K. B. Hanna, A. T. E. Yip Hoi, A. A. Khan, S. H. O'Friel, K. A. Qasem, S. M. Rezaian, H. P. Sinha, J. M. Smith, R. E. Tattersall.

On 1 December the Licence in Surgery and Midwifery of the College was conferred on the following:

R. Bhageerutty, R. W. Charles, G. A. J. Fernandes, H. Govind, E. E. Hansrod, E. O. Isong, A. H. M. Jiwani, M. J. Khetani, Sau-Lan Lau, M. A. Molake, L. A. Mosuro, D. K. Naidoo, A. O. Ogunsola, B. M. Sandy.

Notice to Authors

When original articles and letters for publication are not submitted exclusively to the *British Medical Journal* this must be stated.

Correspondence on editorial business should be addressed to the Editor, *British Medical Journal*, B.M.A. House, Tavistock Square, London W.C.1. Telephone: 01-387 4499. Telegrams: *Atiology, London W.C.1.*

Authors wanting reprints of their articles should notify the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs.

Members' subscriptions should be sent to the Secretary of the British Medical Association, B.M.A. House, London, or to the Scottish Secretary, B.M.A. Scottish Office, Drumsheugh Gardens, Edinburgh.

Information on advertisement and subscription orders appears at the first page of the classified advertisements.

W. J. Irvine: Immunological Aspects of Endocrine Disorders and Atrophic Gastritis.

INSTITUTE OF NEUROLOGY.—6 p.m., neuro-otological clinical meeting.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Medical Automation Experimental Unit of University College Hospital, 69-71 Chancery Mews, London W.C.2, 8.15 p.m., Automation in Medicine. Demonstration and discussion will follow.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—5 p.m., Douglas Guthrie history of medicine lecture by Lord Brock: Surgery Before 1850 as Illustrated by the Operating Theatre of Old St. Thomas's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Cecil Joll lecture by Professor R. Y. Calne: The Present Position and Future Prospects of Organ Transplantation.

ROYAL POSTGRADUATE MEDICAL SCHOOL.—4 p.m., Mr. W. P. Cleland: Management of Lung Cancer.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—7.30 p.m., symposium: Onchocerciasis, Entomological Aspects. Discussion will follow.

RUNWELL HOSPITAL.—At Wickford, Essex, 8 p.m., Dr. D. M. Shaw: Electrolytes in Psychiatry.

Friday, 15 December

BRITISH INSTITUTE OF RADIOLOGY.—2.30 p.m., Malignant Disease in Children.

BRITISH TUBERCULOSIS ASSOCIATION.—At Royal College of Physicians of London, 2 p.m., symposium: The Alveoli.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—3 p.m., Mr. J. R. Cameron: Melanoma.

ROYAL POSTGRADUATE MEDICAL SCHOOL.—(1) 10.15 a.m., Sir Clifford Naunton Morgan: Inflammatory Diseases of the Colon. (2) 11.30 a.m., Mr. A. K. Monro: clinicopathological conference (rectal).

Saturday, 16 December

BRITISH INSTITUTE OF RADIOLOGY.—At Royal Society of Medicine, 10 a.m., meeting with Faculty of Radiologists, Royal College of Surgeons of England, and Radiological Section of R.S.M.

Appointments

BIRMINGHAM REGIONAL HOSPITAL BOARD.—R. M. B. Dowling, M.B., F.F.A.R.C.S. (whole-time consultant anaesthetist to the Hereford group); H. D. L. Campion, M.B., M.R.C.P. (whole-time or maximum part-time consultant physician (geriatrics) to the North Staffordshire group); C. Berry, M.B., D.P.M. (whole-time or maximum part-time consultant psychiatrist to the South Warwickshire group); B. G. P. Macnamara, M.B., M.R.C.P., D.C.H. (whole-time or maximum part-time consultant paediatrician to the Coventry group).

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—M. Strachan, M.R.C.S., D.P.M. (consultant psychiatrist, Ida Darwin Hospital, Fulbourn).

HOME OFFICE.—H. W. Eldridge, M.R.C.S., M.R.C.G.P. (senior medical officer, H.M. Prison, Wormwood Scrubs, London W.); M. W. Fowles, M.B., D.P.M. (medical officer, H.M. Prison, Lincoln); N. A. J. Mullen, M.B., D.P.M. (medical officer, H.M. Prison, Leicester).

MANCHESTER REGIONAL HOSPITAL BOARD.—K. S. R. Bedi, M.B., M.R.C.P.Ed., D.C.H., D.P.M. (whole-time or maximum part-time consultant psychiatrist, Parkside Hospital, Macclesfield); P. J. N. Howorth, M.Sc., M.B. (consultant pathologist with special interest in chemical pathology, Blackburn and District group of hospitals); D. K. Mukerji, M.B., F.F.A.R.C.S. (whole-time consultant anaesthetist, Bolton and District group of hospitals); E. A. G. Hamilton, M.B., D.M.R.D. (whole-time or maximum part-time consultant radiologist, North Lancashire and South Westmorland group of hospitals).

MINISTRY OF OVERSEAS DEVELOPMENT.—J. E. Blewett, M.D., F.F.R. (senior diagnostic radiologist, Government of Barbados).

NATIONAL HOSPITALS FOR NERVOUS DISEASES.—Patricia Painter, M.B., F.F.A.R.C.S. (consultant anaesthetist).

NORTH-EAST METROPOLITAN REGIONAL HOSPITAL BOARD.—Shona Hodgson, M.B., D.Phys.Med. (consultant physician in physical medicine to Thames group of hospitals).

NORTHERN IRELAND HOSPITALS AUTHORITY.—P. J. Molloy, M.B., F.R.C.S. (consultant cardiac surgeon, Belfast Group); T. Freeman, M.D., M.R.C.P.Ed., D.P.M. (consultant psychiatrist, Holywell Group); P. B. Donnelly, M.B., F.F.A.R.C.S. (consultant anaesthetist, South Down Group); J. B. Walsh, M.B., M.R.C.P.I., D.P.M. (consultant psychiatrist, Tyrone and Fermanagh Hospital, Omagh).

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—T. Kumarasamy, M.B., F.R.C.S., M.R.C.P., M.R.C.O.G. (lecturer in the obstetric unit).

Deaths

Playfair.—On 21 November, at Dundee Royal Infirmary, Bessie Morrison Playfair (née Davidson), M.D., D.P.H., in her 71st year.

Pointers

Carcinoma of Lung: Low incidence of tumour produced in mice exposed to cigarette smoke and air mixture (p. 637).

Spread of Staphylococci: General-practice survey in Edinburgh and North-east England showed that newborn babies acquired *Staph. aureus* more frequently in hospital than at home, but hospital strains were no more likely to spread within the family or to cause septic lesions than "domestic" strains (p. 642).

Liver Transplants: Prolonged survival obtained in pigs by Professor R. Y. Calne and his team, without the use of immunosuppressive agents, is thought to be a species effect (p. 645).

Diagnosis of Bacteriuria: Description of bacteriological culture method not requiring incubation at 37° C. and suitable as a screening method in general practice (p. 649).

Blood Loss in Haemodialysis: Reduced by wash-back technique using 1 litre of saline at end of dialysis (p. 651).

Traveller's Diarrhoea: Controlled prophylactic trial showed that this was reduced by Streptotriad (p. 653).

Urinary Leucocyte Excretion: Abnormality found before or after prednisolone provocation test in high proportion of pregnant women was not due to renal disease, and its cause is unknown (p. 655).

Cardiac Scleroderma: Dr. E. Fletcher and Dr. P. Morton show that its features may be masked by lung disease (p. 657).

Case Reports: Hypercalcaemia and carcinoma-tosis (p. 658); Budd-Chiari syndrome after oral contraceptives (p. 660); hepatomegaly and non-metastatic liver-cell dysfunction with hypernephroma (p. 660); relapsing polychondritis (p. 661).

Dysphagia: Dr. C. F. Hawkins's Current Practice article emphasizes the importance of careful history-taking and radiology (p. 663).

Nurse in General Practice: Use for making first visits to patients described by Dr. J. Weston Smith and Mrs. E. M. Mottram (p. 672).

Partnership in Medical Care: Summary of Maurice Bloch Lecture by Minister of Health (p. 675). Leader at p. 634.

Thamesmead: Plan for main and temporary mobile health centres (p. 676).

Operating-theatre Design: B.M.A. Symposium to commemorate Lister centenary (p. 678).

Salmonellae: Importance of animal reservoirs emphasized by Dr. R. C. Huckstep (p. 681).

G.M.C.: Report of Disciplinary Committee (Supplement, p. 77).

Review Body: Mr. Quintin Hogg, Q.C., to represent hospital staff (Supplement, p. 79).

Localization of Intracranial Tumours

Nearly a century ago Sir William Macewen (1848-1924), the father of brain surgery, described the brain as "the dark continent."¹ By this he meant there are seldom unequivocal signs or symptoms pointing accurately to the position of an intracranial mass. The brain surgeon cannot delve with his hand deeply into the brain, as the abdominal surgeon may into the abdomen, so that the dark continent remained dark after Macewen's time. But new methods of obtaining radiological contrast in the brain and of scanning it by means of radioactive isotopes have allowed much more precise information to be obtained. Nowadays it is usually possible to predict fairly accurately both the position of an intracranial mass and its pathological nature.

X rays were discovered in 1895, and as early as 1912 A. Schüller² wrote a book on the radiology of the skull, showing how valuable information could be obtained by accurate interpretation. W. E. Dandy³ introduced ventriculography and air encephalography in 1917, E. Moniz⁴ arteriography in 1927, and G. E. Moore⁵ isotope encephalography in 1948. Meanwhile H. Berger⁶ had introduced the electroencephalograph, and L. Leksell⁷ applied ultrasonics to the brain in 1955. But it is only in the last few years that all these methods have been clearly correlated. The diagnostic use of air in the brain and cerebral arteriography both carry a slight morbidity and even mortality. The modern trend, therefore, is to try to obtain the maximum information by other and harmless procedures. This course also has an economic advantage in saving the occupation of hospital beds. Concurrently with the discovery of these new techniques over the years clinical neurologists, psychiatrists, clinical psychologists, neuro-ophthalmologists, and neuro-otologists have made advances which enable them to point more firmly towards the diagnosis before ancillary aids have to be called in.

When an intracranial mass is suspected the skull is x-rayed. Four radiographs in appropriate projections are usually a sufficient survey, but if a lesion in the region of the optic or acoustic nerves is suspected it is necessary to take special projections in addition. In adults the chest is x-rayed as a routine. This is essential if the patient is middle-aged or over, because bronchial carcinoma, a frequent source of metastases in the brain, is now such a common disease. An E.E.G. and ultrasound examination can readily be performed at the same time. Having obtained the results of these examinations, the neurologist can then review the situation and decide what further investigations, if any, are necessary.

Before considering the more elaborate methods of radiological investigation it is important to be clear about the types of intracranial mass which might be found and their incidence. Firstly, it is not always possible to differentiate clinically between neoplasms, vascular lesions, and inflammatory masses. About one-half of all intracranial tumours belong to the glioma family; these infiltrate the brain in a haphazard fashion and usually have no discrete edge. About four out of five of them are

malignant. The majority of the remaining intracranial tumours are extracerebral—that is, with the important exception of metastases they press on rather than invade the brain. Meningiomas and pituitary tumours each account for about 15%, acoustic neuromas for about 8%. Intracerebral metastases were found to be relatively rare until recent times, accounting for rather less than 5% in most large series reported from neurosurgical clinics. However, nowadays the figure approaches 10% and may be more. Other types of tumour, though important, are relatively rare. Among the most likely non-neoplastic conditions are abscess, subdural haematoma, and intracerebral haematoma.

The pattern of investigation will vary much from patient to patient, depending partly on the provisional clinical diagnosis and partly on the patient's state of health. The latter can vary from almost normal health to intense coma associated with severe papilloedema. Before the invention of isotope scanning it was nearly always necessary to admit any case of suspected brain tumour to hospital for investigations. Nowadays this is not always essential, and the economic and social advantages of outpatient investigation are obvious. A good example is the case of a middle-aged or elderly person, usually male, who develops perhaps slight symptoms and signs of an intracerebral mass. Plain radiographs of the skull may be negative, and even if a mass is present in one hemisphere the pineal gland (if it is calcified) is not always deviated sufficiently to enable the radiologist to confirm it. However, the ultrasound examination will usually be positive in such cases and so may be the E.E.G. The chest will be x-rayed as a routine, for bronchial carcinoma is far and away the commonest primary site of a secondary in the brain. The next step is to scan the brain after injection of a radioactive isotope. This merely entails a small intravenous injection and is readily carried out on outpatients. If the chest x-ray is abnormal, and the scan shows more than one intracranial mass, the diagnosis is virtually certain. As many as six or seven metastases have been shown on brain scans, but the limiting factor is the size of the metastases, those less than 2 cm. in diameter not being demonstrable. Meningiomas nearly always give a positive scan, and a high percentage show characteristic changes on a plain radiograph. If these changes can be related to the size, shape, and position of the mass shown on the scan the diagnosis is sometimes sufficiently certain for a surgeon to explore. Scanning is usually positive with malignant gliomas and the larger acoustic tumours, and with subdural and intracerebral haematomas, but seldom with the pituitary group of tumours.

The large majority of patients suspected of having an intracranial tumour require admission to hospital. They are ill, and, besides needing expert nursing attention, many have to be examined by cerebral angiograms and air studies entailing the injection of air (pneumography) at lumbar puncture (lumbar encephalography) or by ventriculography. One or more of these investigations is frequently necessary even if the scan examination is positive, for the scan seldom provides all the necessary information on the site and nature of the tumour.

In the last few years most European and American neurosurgeons have tended to recommend carotid arteriography before pneumography. Arteriography has the advantage of not upsetting the intracranial hydrodynamics, which is inevitable when air is introduced by whatever route. Thus the patient is generally less upset after an angiogram. On the other hand, an angiogram is more limited in the information it gives. Thus one internal or common carotid

arteriogram may give useful information about one cerebral hemisphere but usually little or nothing about the opposite hemisphere or the mid-brain or posterior-fossa structures. Pneumography, on the other hand, outlines the whole ventricular system, and if the air is introduced by lumbar puncture the cisterns and sulci of the brain are also outlined. If there is a strong suspicion on clinical examination, ultrasonic testing, the E.E.G., plain radiography, and scanning that a lesion is restricted to one hemisphere then carotid angiography on that side is indicated as the first contrast investigation. This may show the position of the lesion by the deformity produced on the arteries and veins, and sometimes, in addition, characteristic pathological blood vessels may be outlined, as, for example, in meningioma and malignant glioma. Sometimes, however, arteriography does not give all the information required. Pneumography is then needed to provide further information. If the patient shows signs and symptoms of grossly raised intracranial pressure it is usually considered safer to undertake a ventriculogram, but if these signs are absent more information can be obtained by undertaking a lumbar encephalogram. The position of the tumour can be analysed by noting the deformity of the ventricular system or the subarachnoid pathways.

Sometimes it is impossible to determine clinically or by the preliminary radiological and other investigations whether the suspected mass is supratentorial or infratentorial, and so there is no pointer to which arterial tree should be outlined. In these cases an encephalogram should be undertaken before an arteriogram. Then again, if the lesion is thought to be lying in the mid-brain or posterior fossa, experience shows that pneumography is more reliable in delineating the lesion than either carotid or vertebral arteriography.

There is yet another useful radiological investigation which has a small place in the diagnosis of tumours, and that is positive contrast ventriculography. It is valuable in outlining masses in the mid-brain or posterior fossa. Patients with such lesions usually suffer from moderate or considerable hydrocephalus, and an air ventriculogram can severely upset the intracranial hydrodynamics. With positive contrast ventriculography only 2–3 ml. of contrast substance needs to be used; it is then manipulated into the appropriate part of the ventricular system under television control. By this means there is no serious upset of intracranial hydrodynamics. In addition, a positive contrast substance has the advantage in sometimes delineating the lesion far more sharply than a small air shadow might.

Since such remarkably refined methods of radiological investigation are now available, it might be thought that no tumour or mass will remain undetected. Unfortunately this is not the case. Very small tumours, such as meningiomas pressing on the optic nerve, can evoke serious signs and symptoms, yet by virtue of their small size may not be detectable by any radiological method. Again, large infiltrating gliomas may fail (sometimes for years) to distort the ventricular or arterial anatomy and may also fail to take up an isotope. Thus in the last resort the astute neurologist or neurosurgeon must make the final decision, sometimes defying the results of all the negative investigations.

Acalculous Cholecystitis

The great majority of patients with disease of the gall bladder have stones in it, yet there is no doubt that acalculous cholecystitis, though unusual, does exist. In practice the conditions found at operation may range from a perfectly normal gall bladder removed because of suspected biliary disease, through gall bladders with mild histological changes in the wall, to undoubted examples of acute, indeed even gangrenous, cholecystitis in the absence of stones.

For some time the poor prognosis of patients submitted to cholecystectomy despite the absence of gross lesions in the gall bladder and with a cholecystogram that was only questionably abnormal cast doubt on whether a definite disease entity was being diagnosed. Thus W. A. Mackey, in a review of 243 such patients,¹ found over one-third had a poor functional result. He concluded that cholecystitis without stone "seems to belong to a region on the border line between functional and organic disease."

More recently F. Glenn and H. Mannix² studied a group of 135 patients who had neither stone nor acute inflammation; these patients were in a series of 3,110 undergoing cholecystectomy. The results were somewhat unhappy; 22 had severe postoperative complications (16.3%) and there were three deaths. Of 121 of the patients followed up, a quarter had no relief from their original symptoms. Careful microscopical examination of the excised specimens showed no difference between those cases with good results and those with no improvement, so that these authors state, "One may well question the actual role of cholecystectomy in the clinical improvement."

Yet undoubtedly acute cholecystitis, even progressing to frank gangrene and perforation, can occur in the absence of a stone. S. O. Hoerr and J. B. Hazard,³ in reviewing 14 such cases, define four possible causes. There may be non-calculous obstruction of the cystic duct from fibrosis, kinks, or twists, or from an anomalous cystic artery or tumour. There may be infarction of the wall of the gall bladder due to arteriosclerosis or embolism. There may be reflux of pancreatic juice, producing a chemical cholecystitis. Or there may be bacterial invasion of the gall bladder wall. Typhoid cholecystitis is a good example of the last group.

An interesting review of the whole subject of acalculous cholecystitis has recently come from A. M. Munster and J. R. Brown,⁴ of the Peter Bent Brigham Hospital, Boston. Out of 541 cholecystectomies 12 cases of acalculous cholecystitis were found (2.2%). There were four examples of acute cholecystitis, three more showed undoubted active chronic disease, and the remaining five had only minimal evidence of mild chronic cholecystitis. Not unexpectedly the patients with acute acalculous cholecystitis did well after surgical operation, whereas of the five with minimal disease two had persistent symptoms and one has been lost to follow-up.

The situation can be summed up as follows. If a patient has typical symptoms and signs of gall-bladder disease in the absence of radiological evidence of stone and with normal appearances on barium-meal examination of the upper gastrointestinal tract, the surgeon may still find himself forced to perform a laparotomy. He may detect some unsuspected lesion—for example, chronic pancreatic disease.

He may find tiny stones in the gall bladder which were undetected on x-ray examination, or there may be evidence of acalculous cholecystitis with gross thickening and inflammation of the wall of the gall bladder, adhesions to adjacent viscera, and other signs of disease. In these circumstances cholecystectomy will probably relieve the patient's symptoms. If the gall bladder appears normal, if the aspirated bile is clear, and if stones can still not be felt when the organ has been completely emptied, cholecystectomy is unlikely to be of value and will merely add to the possible risk of the exploratory operation.

Novelty at Nottingham

The creation of a complete new medical school at Nottingham presents the opportunity for putting into practice many of the imaginative ideas discussed at three world conferences on medical education and innumerable smaller gatherings since the war. It is therefore refreshing to see that a report¹ published this week offering recommendations for the administration of the teaching hospital contains an entirely novel proposal. This concerns the relationship between the teaching hospital, Nottingham University, and Sheffield Regional Hospital Board.

The central problem for a large undergraduate teaching hospital is to reconcile the need to provide comprehensive medical care to the population among whom it is set with the obligation to teach. In addition, it must offer facilities that will allow and even encourage research. For a variety of reasons England and Wales took a different path from Scotland when the National Health Service was introduced, and arrangements in Northern Ireland are again slightly different. Despite some criticisms over the years it cannot be said that there is any great dissatisfaction either with the separation of boards of governors of teaching groups from regional hospital boards in England and Wales or with the co-ordination of their functions under single boards beyond the Border. But when the local joint committee of Sheffield Regional Hospital Board and Nottingham University came to look at the problem it faced plans which, as its report says, are "without precedent or parallel in the United Kingdom." And these words too are a refreshing token of the Nottingham planners' disinclination, evident in the report, to follow precedent or trot along parallel lines.

If the new teaching hospital was placed under the existing regional hospital board it would have the disadvantage of being controlled by a body 40 miles away and separated by congested lines of communication. It is a body, too, which in England and Wales has no statutory responsibility to provide the university with facilities for teaching. Yet the setting up of new and elaborate hospital services for a large population can be done satisfactorily only in the closest co-operation with the existing regional board. This consideration, combined with the difficulties of communication that would hamper a separate board in Nottingham have weighed against the establishment of a new board of governors.

What the joint committee therefore recommends is a governing body—"University Hospital Board of Manage-

³ Hoerr, S. O., and Hazard, J. B., *Amer. J. Surg.*, 1966, 111, 47.

⁴ Munster, A. M., and Brown, J. R., *ibid.*, 1967, 113, 730.

¹ Sheffield Regional Hospital Board and the University of Nottingham, *Report on the Form of Government for the Teaching Hospital at Nottingham*, 1967. 2s. net. Obtainable from Secretary to Sheffield Regional Hospital Board, Fulwood House, Old Fulwood Road, Sheffield S10 3TH.

ment"—to be appointed by and responsible to Sheffield Regional Hospital Board but having wider powers than ordinary hospital management committees. The new board of management would have 15 members plus a chairman. Six would be nominated by Nottingham University and nine appointed by Sheffield Regional Hospital Board after consultation with local health authorities, executive councils, medical and dental staffs, and other organizations. The chairman would be appointed by the regional board after consultation with the university. On the all-important financial powers of the board of management the report goes on to recommend that it should be empowered to undertake capital works on the same conditions as is a board of governors, and that the Ministry of Health should earmark revenue allocations to the regional board for use by the board of management. Collaboration between the regional hospital board and the new board of management is to be further ensured by the creation of a special co-ordinating committee.

The joint committee's proposals, which have been approved by Nottingham University and Sheffield Regional Hospital Board, go to the Ministry of Health for consideration. They will also be more widely studied for their general interest. Though these are interim measures and are specifically intended for the novel situation at Nottingham, they must be thought relevant to the establishment of other new medical schools—for instance, the one at Southampton.

Monarticular Arthritis in Children

The child with chronic arthritis in a single joint can present a difficult problem in diagnosis. No doubt tuberculosis was once the commonest cause, but tuberculosis of joints is now seen much less frequently in Britain, and a number of other conditions have to be considered. These are rheumatoid arthritis (together with ankylosing spondylitis, psoriatic arthritis, and the arthritis of ulcerative colitis, which when presenting in a single peripheral joint are often indistinguishable from rheumatoid disease); the effects of injury, such as osteochondritis dissecans; and a very small group of rarer miscellaneous disorders, including brucellosis, histoplasmosis, blastomycosis, pigmented villonodular synovitis, synoviomia, haemangioma, and other tumours.

Juvenile rheumatoid arthritis, or Still's disease, usually affects multiple joints, but the onset is sometimes monarticular, and this form of the disease has been described in several recent studies.¹⁻⁹ The proportion of patients with Still's disease starting in a single joint varies in the different series from 10%⁴ to 39%³—no doubt owing to differences in case selection and in diagnostic criteria. Sex and age of onset do not appear to differ from Still's disease as a whole.

The knee is predominantly affected, with the ankle next most commonly; other joints include wrist, hip, elbow, midtarsal, and various joints in the fingers, toes, and cervical vertebrae. In some children the disease remains monarticular, but most eventually progress to a polyarthritis, usually within a year. Remission of disease activity is commoner in those with persistently monarticular disease than in those in whom it becomes polyarticular. Other useful signs of Still's disease, such as the typical fever and rash, are seen only occasionally in these patients. Though iritis is not always found among children with monarticular disease,⁵ it must be looked for carefully, because most reports indicate that it occurs with at least equal frequency to that in polyarticular disease, while in three series^{4, 7, 9} the incidence was higher in the monarticular group.

The main radiographic features consist of local growth abnormalities—longitudinal overgrowth of long bones, enlargement of epiphyseal ossification centres, accelerated epiphyseal maturation, and diminished size of small round bones such as the carpals. Erosion of bone is relatively late and inconspicuous. As with the polyarticular form of Still's disease, serological tests for rheumatoid factor are usually negative and the vascular complications of adult rheumatoid disease are rarely encountered.¹⁰ The appearances of biopsy specimens of synovium vary from a mild synovitis with some hyperplasia of synovial lining cells and minimal round cell infiltration to the classical appearance of rheumatoid synovial membrane with marked hyperplasia, lymphocyte aggregations, plasma cell infiltration, and deposition of fibrin. There is little correlation between the findings at biopsy and the subsequent course of the disease,⁴ but the procedure is of great value in excluding the presence of tuberculosis and other conditions.

There should therefore be no hesitation in carrying out synovial biopsy when—as is usually the case—some doubt exists about the diagnosis. General physical and ophthalmic examination, radiology of joints and chest, tuberculin testing, and microscopic and bacteriological examination of synovial fluid may all help in reaching the answer, but very often results are inconclusive. A needle biopsy nearly always yields adequate tissue for diagnostic purposes and causes none of the discomfort and inconvenience of an open surgical procedure, though the latter has the advantage of permitting direct inspection of the joint and selection of tissue for examination. Whatever the method, early biopsy avoids on the one hand any delay in the diagnosis of tuberculosis and on the other the equally unwarranted mismanagement of Still's disease with antituberculosis chemotherapy and harmful immobilization.

Partnership in Medical Care

Wherever the State and the medical profession come into working contact there seems to be excessive friction. Though in Britain there have been none of the "strikes" that periodically affect doctors in some other countries, relations between the Ministry of Health and the profession have at times been strained and have seldom been cordial. Mr. Kenneth Robinson took up the theme of the relationship between doctors and the State in his Maurice Bloch Lecture to Glasgow University last week, a summary of which is

printed at page 675. His subject was partnership in medical care provided under the National Health Service.

Mr. Robinson sees a relationship of mutual confidence between Government and profession as being essential if the N.H.S. is to achieve its full potential. He is puzzled that the efforts of successive Ministers of Health have failed to convince doctors that their suspicions of authority are groundless. He thinks that more doctors, particularly the younger ones, are happier in their environment than their leaders make out, and he notes in the public utterances of the profession's spokesmen a reluctance to give credit to the Government for what it has done and what it has said it intends to do for the Health Service.

There can be some sympathy for Mr. Robinson. He is sincere, and more than most of his predecessors in office he has tried to meet the doctors half way. They, on their part, have been quick to learn the practices of collective bargaining but perhaps slower to discover how to make their authoritative voice heard on matters more directly concerned with the well-being of a profession and of the public which it serves. And, however well intentioned, Mr. Robinson inevitably suffers from any layman's inability fully to understand the finer professional feelings of the doctors with whom he is dealing.

It is a welcome sign that Mr. Robinson has caught the new mood of objective inquiry into the working of the N.H.S. It is to be hoped that his review of its administrative structure will result, as he expects, in reforms that will put the management into proper shape to serve the needs of modern scientific medicine. He also sees the need for an administration that will lead to better co-operation in the functioning of the various branches of the medical services. But whatever changes come about—unless perchance they include a revolutionary decentralization of the responsibility for the provision of medical services—they are unlikely to do much to promote that partnership between the Government and the profession that Mr. Robinson is not alone in thinking to be desirable.

Partnership implies a division of work and a sharing of responsibility among equals. There is no difficulty in differentiating the work of the Minister of Health and his Ministry from that of the doctors. But when Mr. Robinson speaks of partnership does he mean one in which doctors would share equally with him the responsibility for making decisions? It is to be feared that he does not. Indeed, can he share responsibility that is placed on him by statute? The National Health Service multiplied the men in Whitehall and, for better or for worse, made them the masters of the men in the field. That has probably been the greatest single cause of the doctors' discontent, and it is at the root of their mistrust of Government.

Rather than pondering on the irrational behaviour of a seemingly unappreciative lot of doctors or surmising how many younger ones are happier than they are said to be, Mr. Robinson would do well to begin a dispassionate examination of the nature of the discontents that undoubtedly exist. Why do young doctors emigrate? What is there in their new environment which they think will give them the professional satisfaction that they failed to find in the N.H.S.? Why should discontent be if anything more rife among a generation that has never known anything but the N.H.S. than among their older colleagues? The answers to these and other questions might produce some facts which would lead to a better understanding by the Government of the profession's problems, and if not to a true partnership at least to an increase in mutual confidence.

Tetanus Prophylaxis

The treatment which should be given to prevent tetanus in injured patients is still not fully agreed. Each of the prophylactic methods available has drawbacks, and in addition to the difficulties of choosing between them on clinical grounds the doctor must also be concerned that medico-legal complications have an unfortunate association with tetanus and its prevention.

Under ideal circumstances, where the whole community has been actively immunized, there are few difficulties: patients then require only normal surgical toilet of the wounds, together with an injection of tetanus toxoid if more than two or three years have elapsed since a previous booster dose. Such ideal conditions exist in Britain only in the armed Forces and in some industries and institutions. Probably well under half of the general public have been actively immunized, and of these many are unaware of the fact and must often be regarded as non-immune when treated for an injury. Most casualties are thus either non-immune or doubtfully immune, and it is with these patients that the main difficulties of tetanus prophylaxis arise. Almost all of the difficulties would be solved if human tetanus antitoxin could be used; an injection of 250 units provides at least four weeks' protection and is virtually free from side-effects.¹ But only small amounts are available in Britain and at present prophylaxis must be provided by other means.

The first essential of tetanus prevention for all wounds (irrespective of the immune status) is a thorough surgical toilet. A decision must then be made whether further prophylaxis is needed. For fresh, clean wounds in which it is possible to remove completely all foreign matter and dead tissue further measures are not required.²⁻⁴ For wounds not seen until six hours or more after injury, however, 1,500 units of tetanus antitoxin (preceded in the usual way by a small trial dose) should be given, because there is a possibility that a lethal amount of toxin might already have accumulated.^{3, 5}

Patients with more severe wounds will usually require some form of prophylaxis in addition to the surgery, particularly if some doubt remains about the completeness of the toilet. If human antitoxin is not available the practical alternatives are horse serum antitoxin and an antibiotic, and the choice between the two is difficult and controversial. Both undoubtedly can fail; there are many reports of tetanus in patients who had received antitoxin,⁶ and in recent years the disease has been encountered in patients given antibiotic prophylaxis at the time of wounding.^{7, 8} It is not known which fails more often, but the failure rate of either in Britain is presumably very low, because tetanus is extremely rare in injured patients given either antitoxin or antibiotic in casualty departments.^{4, 7} As no properly controlled comparison has been made some grounds other than effectiveness must be used to choose between the two.

In addition to sometimes failing to prevent tetanus both antitoxin and antibiotic may cause hypersensitivity reactions, and the available evidence suggests that horse serum is more dangerous in this respect. Mrs. C. A. Cox and her colleagues,⁹ for example, found that in Britain about 12% of patients developed a significant reaction to antitoxin. Of the antibiotics which may be used the penicillins are the group most likely to cause trouble, and, though there are no reliable figures of the incidence of reactions in Britain, in the U.S.A. it is perhaps 1%.¹⁰ On this evidence, therefore, antibiotics are to be preferred to antitoxin for routine use in Britain—though everyone does not agree with this view.⁷ Even when the antibiotic regimen is preferred there will nevertheless be some wounded patients for whom antitoxin is a wiser choice—when the wound is over six hours old, and also when the antibiotic possibly may not penetrate into the infected site, as when severe tissue damage is present or when the wound cannot be completely cleaned.^{3, 5}

A number of antibiotics are suitable for tetanus prophylaxis. If the patient can be trusted to take tablets cloxacillin is a good choice as it is not inactivated by penicillinase, which might be formed in a lesion by bacteria other than *Clostridium tetani*.⁵ If an injectable prophylactic is preferred a combination of long- and short-acting penicillins is suitable provided the wound is not otherwise infected. E. J. L. Lowbury¹¹ recently tested 50 strains of *Cl. tetani* and found that all were fully sensitive to the penicillins and to tetracycline and erythromycin, which also are suitable. Whichever of these antibiotics is used it should be given in full dosage for at least four days—or longer if healing of the wound is delayed, because there is evidence from experiments on animals that shorter periods of treatment can be unreliable.⁵ The local application of antibiotic powder to the wound is worth while,¹² as there is evidence, again from work on animals, that locally injected antibiotic can be particularly effective.¹³

If antitoxin is preferred for routine use, once again there are some patients for whom it is an unwise choice—those believed to be hypersensitive to horse serum as indicated by a history of previous reactions or a reaction to the trial dose.³ The injection of horse serum into a hypersensitive person is not only dangerous but can be valueless, because the serum is likely to be rapidly eliminated from the patient's body; reliance should instead be placed on surgery together with an antibiotic. If, however, as in the case of an extensive, badly soiled wound, antitoxin is considered essential, then every effort should be made to obtain human antitoxin, and small supplies have been made available by the Ministry of Health for this purpose.¹⁴

In addition to the immediate measures taken for preventing tetanus, all authorities advise that wounded patients should be started on a complete course of immunization with adsorbed toxoid.¹⁵ Though protection is unlikely to develop for at least four weeks, after this time the patient should need neither antitoxin nor antibiotic if he is again injured.

Commonwealth Links

At a time when the strong but ill-defined bonds between the countries comprising the British Commonwealth are under stresses of various kinds it is gratifying to note the excellent work being done by the Commonwealth Foundation. Its first report, issued after the initial 18 months of existence, has now appeared.

A registered charity with funds supplied by Commonwealth countries, the Foundation seeks to encourage interchange and co-operation throughout the Commonwealth, especially through the work of professional people in it, as may be seen from its terms of reference:

"(a) To encourage and support fuller representation at conferences of professional bodies within the Commonwealth.

"(b) To assist professional bodies within the Commonwealth to hold more conferences between themselves.

"(c) To facilitate the exchange of visits among professional people, especially the younger element.

"(d) To stimulate and increase the flow of professional information exchanged between the organizations concerned.

"(e) On request to assist with the setting up of national institutions or associations in countries where these do not at present exist.

"(f) To promote the growth of Commonwealth-wide associations or regional Commonwealth associations in order to reduce the present centralization in Britain.

"(g) To consider exceptional requests for help from associations and individuals whose activities lie outside the strictly professional field but fall within the general ambit of the Foundation's operations as outlined above."

To fulfil its aims the Foundation has been endowed with an annual income of £250,000, to which all the following Governments subscribe in varying proportions: Britain, Canada, Australia, New Zealand, India, Pakistan, Ceylon, Ghana, Malaysia, Nigeria, Sierra Leone, Tanzania, Cyprus, Uganda, Jamaica, Trinidad and Tobago, Malawi, Zambia, Malta, the Gambia, and Singapore. Guyana subsequently joined the Foundation in December 1966, Barbados in May 1967, and Kenya in July 1967. The chairman is Sir Macfarlane Burnet, O.M., F.R.S., who in 1960 jointly with Professor (now Sir) Peter Medawar, F.R.S., won the Nobel prize for medicine.

So far the Foundation's grants have been made chiefly to professional people, doctors prominently among them, "to attend worth-while conferences at which they can contribute as well as learn." Both the Commonwealth Medical Association and the British Medical Association have been beneficiaries, the latter by a grant to finance the attendance by members of Caribbean Branches at a regional council meeting in Antigua earlier this year. Many other medical organizations have likewise received grants to enable members to attend conferences on special branches of medicine and surgery. Outside medicine the beneficiaries have included engineers, lawyers, accountants, architects, and educationists. Another venture which promises to be helpful is the establishment in developing Commonwealth countries of "professional centres" with a small staff and a library. So far two have been set up—in Kampala, Uganda, and Port-of-Spain, Trinidad. The aim is that these premises shall be available for professional meetings and lectures.

In fostering professional relations within the Commonwealth the Foundation is helping to bring peace and prosperity to a world badly in need of both. And with a tradition that pays little heed to national frontiers doctors in particular will feel grateful to the Commonwealth Governments for setting up this worth-while organization.

Production of Lung Carcinomas in C57BL Mice Exposed to a Cigarette Smoke and Air Mixture

R. J. C. HARRIS,* PH.D., M.C.PATH.; G. NEGRONI,* M.D.

[WITH SPECIAL PLATE BETWEEN PAGES 640 AND 641]

Brit. med. J., 1967, 4, 637-641

There is no doubt that the tar produced by condensing cigarette smoke is carcinogenic for mice (see Day, 1967). However, lung epithelium differs from the skin and the condensate differs from fresh cigarette smoke in, for example, the absence of the gaseous components. It appeared worth while to us, therefore, to attempt to produce lung carcinomas in mice by allowing them to breathe a mixture of cigarette smoke and air for a prolonged period.

Stewart and Herrold (1962), in a "critique of experiments on attempts to induce cancer with tobacco derivatives," review negative mouse inhalation studies by Lorenz *et al.* (1943) and by Dunn (1943) using Strong A mice (a strain with a 90% spontaneous incidence of lung adenomas at 18 months of age). Essenberg (1952), however, had exposed the same strain of mice to cigarette smoke for 12 to 14 months in a ventilated chamber and *increased the incidence* of papillary adenocarcinomas in these mice.

Mühlbock (1955) also claimed to have *increased the incidence* of lung tumours in a hybrid 020×DBA strain of mouse by puffing smoke from cigarettes into a sealed cage every two hours each day.

We believed, however, that we should use a strain such as C57BL, which apparently have a predominant gene for resistance to the induction of lung tumours (Bloom and Falconer, 1964), and in which Peacock and Peacock (1966) described only one deep-seated spontaneous papillary adenoma in an 817-days-old male.

We were thus aware of many negative results, but were not convinced that these experiments had been conducted under the optimum conditions. In most cases (except for Lorenz *et al.*) there was no evidence that the animals were actually taking the smoke droplets into their lungs.

Most observers agree that lung cancer in man is multifactorial, and that of these other factors chronic respiratory disease (bronchitis, bronchiolitis, and chronic pneumonitis) is probably the most important.

There are two ways in which lung disease might contribute to the occurrence of lung cancer. Firstly, the diseased lung might be less able to prevent retention of particulate carcinogens, such as smoke droplets; and, secondly, infectious agents such as respiratory viruses and mycoplasma might themselves produce areas of cellular proliferation which were susceptible to the effects of inhaled chemical (or viral) carcinogens.

As early as 1920 Winternitz *et al.* predicted that, since the changes produced by influenza viruses in the lung looked preneoplastic, the 1919 influenza pandemic should give rise

to lung cancers later. Straub (1937) observed similar lesions in the lungs of influenza-virus-infected mice, but single infections had no apparent effect in increasing the lung cancer incidence in A (lung adenoma-prone) or C57BL (lung adenoma-resistant) mice (Steiner and Loosli, 1950).

The studies of Kotin and Falk (1956) and Kotin *et al.* (1958), however, have now confirmed for mice the earlier hypothesis. They found, for example, that following infection with PR-8 and Lee strains of influenza the bronchial and bronchiolar epithelium of mice regenerated after about seven days, but that peribronchial hyperplastic foci remained for some time. Sendai (parainfluenza) virus produced extensive necrosis of the epithelium, followed by regeneration. Kotin *et al.* infected mice successively with these strains, hoping that the squamous metaplasias so produced would "progress" to squamous carcinoma.

The carcinogen employed by Kotin *et al.* was a "smog" of ozonized hydrocarbons. The animals given both influenza and smog showed areas of squamous metaplasia in their lungs, and where keratin was detected preneoplastic or neoplastic changes were also observed. The experiments ran for 31 months (Kotin, 1966), and whereas no squamous cell carcinomas (but only pulmonary adenomas) were found in control "smog"- or "flu"-treated groups the smog and influenza groups had 10% squamous cell carcinomas (33/328 mice). Kotin, however, gave no data concerning the transplantability of these tumours. Leuchtenberger and Leuchtenberger (1966) observed very similar histology for influenza-infected mouse lung. When mice were subjected to cigarette smoke in a large chamber "atypical proliferative lesions" were described by the same authors, and when these treatments were combined the dysplastic lesions of the bronchi and bronchioles were similar to those produced by influenza alone, but in addition there were histopathological features in the lung "resembling bronchogenic carcinoma."

We proposed, therefore, to study also the effect of previous infection with influenza viruses on the induction of lung tumours by cigarette smoke in the C57BL mice. There were, of course, a number of control groups of mice. Thus in summary:

Group 1: Exposure to infection by one or more serologically non-overlapping influenza virus aerosols.

Group 2: Exposure to an aerosol of 3:4-benzpyrene.

Group 3: Exposure for life to a cigarette smoke and air mixture.

Group 4: A combination of group 1 followed by group 2.

Group 5: A combination of group 1 followed by group 3.

Group 6: Exposure to aerosols of the aqueous suspending media for the virus or benzpyrene.

* Division of Experimental Biology and Virology, Imperial Cancer Research Fund, Mill Hill, London N.W.7.

An interim account of the experiments is given by Harris and Negroni (1966).

Materials and Methods

Mice.—Young adult C57BL mice of both sexes, random bred in these laboratories, were used. Their past history showed that they had a long life-span, a low incidence of spontaneous tumours of all kinds (but *not* of leukaemia, see below), and a nil incidence of lung carcinomas, though *thymectomized* mice of a hybrid CBA × C57BL strain do develop these (D. M. V. Parrott, personal communication).

Aerosol Production.—The aerosol generator of "closed-circuit" design described by Henderson (1952) gave reproducible results not only for the influenza viruses but also for the benzo(a)pyrene.

Influenza Viruses.—Whereas Kotin and Falk (1956) had used PR-8, Lee, and Sendai, we employed W.S., Swine, Lee, and Singapore strains. These were grown from seed virus in RIF-free embryonated Brown Leghorn eggs from our own closed stock. These strains are antigenically unrelated, and the immune response of the mouse to one strain does not interfere with subsequent infection with another. Where mice were infected with more than one strain there was one month's interval between infection, so that interferon, which is believed to play a part in oncogenesis by other viruses, might not interfere with subsequent exposure to carcinogens. Small doses of the influenza viruses produce pneumonia in the mice but do not kill them, and so this optimum dose had to be determined by direct titration of each virus in mice and in the embryonated eggs. Intranasal instillation or aerosols were used, but the latter gave a more reproducible result and a more uniform distribution of lung lesions in the infected mice. Ten animals were exposed at a time, and the aerosol technique only was used for the combination treatment of mice with viruses and cigarette smoke.

Benzo(a)pyrene.—The aerosol was generated from a solution of 3:4 benzo(a)pyrene (32 mg.) in aqueous (0.5%) gelatin (250 ml.) containing 1:10,000 thiomersalate.

Cigarette Smoke Generator

In preliminary investigations groups of mice were exposed to a smoke and air mixture in a 400-litre plastic chamber originally designed by Amsco as a sterile isolator for housing germ-free mice. A standard smoking-engine (ITC) used for the production of tobacco smoke condensate was adapted by H. G. East and Co. (Sandy Lane West, Littlemore, Oxford) to produce a dilute mixture of fresh cigarette smoke in air. We chose a ratio of 1:39 (25 ml. smoke to 975 ml. air), which approximates to that of one puff of a cigarette in the tidal volume of the human lung.

Under equilibrium conditions (72 cigarettes smoked) the nicotine concentration in such a chamber reached 0.1 mg./l. (Harris and Negroni, 1966), which the mice tolerated for more than three hours without apparent distress. Moreover, analysis of their lungs after such a period failed to reveal the presence of nicotine. We concluded that, under conditions of high humidity—condensation was readily apparent on the walls of the chamber—the hygroscopic smoke droplets (containing the nicotine) had increased in size until they were too large to penetrate to the lower respiratory tract of the mice.

We then developed a new type of manifold (Fig. 1) based on the machine developed by Henderson (1952) for the exposure of animals to aerosols of bacteria, etc.

In such a machine a fresh cigarette smoke and air mixture is continuously passed across the noses of the mice, and the noses alone are in contact with it. The concentration of nicotine in the mixture was again about 0.1 mg./l. (and the CO

concentration—0.064 volume %—much less than that in the large chamber—0.16 volume %). Under these conditions we found that the mice were initially unable to tolerate exposure for more than 12 minutes,* and that when they died under exposure the nicotine content of their lungs varied between 14 and 17 µg. (Harris and Negroni, 1966).

FIG. 1.—Plastic manifold for exposing mice to smoke and air mixture. The mice are held around the neck in metal boxes so that only their noses are in the smoke and air stream. The boxes are attached to the manifold magnetically. Reprinted by permission, from *Lung Tumours in Animals*, edited by L. Severi, University of Perugia, 1966.)

We then adopted the procedure of exposing 10 groups of 20 male and female C57BL mice to the smoke/air from 12 cigarettes (taking 12 minutes) every other day for the duration of their lives.

Controls

Control groups of equal numbers of each sex were housed under identical conditions and fed the same diet and water *ad libitum*. Each control group (50 males and 50 females) had been exposed to an aerosol of an aqueous suspending medium used to produce aerosols of influenza viruses (the results of these experiments will be separately reported) or of benzo(a)pyrene. Another control group consisted of 200 C57BL mice exposed on four occasions at monthly intervals (beginning when they were 5 months old) for a period of 10 minutes to an aerosol of 3:4-benzo(a)pyrene (32 mg.) in aqueous (0.5%) gelatin (250 ml.) containing 1:10,000 thiomersalate as a preservative in the Henderson machine. We calculated that in such an exposure the mice would receive in their lungs about as much 3:4-benzo(a)pyrene as they would receive from two years' exposure to the smoke and air mixture.

When each animal died a careful search was made to determine the cause of death. Sick animals were usually killed so that it might be possible to attempt transplantation (and thus to confirm malignancy) of any lung tumours produced.

Results

We had originally believed that strain C57BL had a low incidence of lymphosarcoma/leukaemia, but it became apparent, as the groups of mice aged, that the studies of others had probably not been continued in sufficiently elderly mice. Table I shows the cumulative incidence of lymphosarcoma/leukaemia in all groups for each sex.

Table II shows the cumulative incidence for all deaths, except for malignancies, for each sex in each group.

Mice also died from other tumours, and these are listed in Table III. Table IV (p. 640) shows the incidence of lung carcinomas in the six groups.

Control ..	100	100	5 (31)	6 (28)	1 (20)	2 (18; 33)	1 (30)	1 (31)

Figures in parentheses are mean ages at detection in months.

Pathology

The following account of the pathological observations is reported in two sections: the first refers to the changes, other than lung lesions, observed in mice belonging to the various groups. The second is a detailed account of the macroscopic and microscopical changes in the lungs of mice which are summarized according to the treatment the animals received.

Lesions other than those Found in the Lungs

All the mice, no matter to which group they belonged, showed various lesions other than lung lesions. These, however, were common to all groups, and occurred quite independently of the treatment which the mice received. C57BL mice were chosen because, according to the current literature, they are supposedly free from tumours. This proved to be untrue, as lymphosarcoma/leukaemia occurred in a very high incidence in all groups of mice (Table I).

The incidence was the same in all groups, if one takes into account only animals which survived more than 20 months. A higher mortality rate before this age was observed in male mice treated with benzpyrene (Table II) and in females treated with influenza viruses (Table II). The incidence of leukaemia appeared to be lower in these groups than in the control group (Table II), but only because in these groups the mortality rate was higher up to 20 months of age.

Hepatitis of the type described by Tyzzer (1917), and more recently and carefully studied by Craigie (1966), in these laboratories was one of the major causes of death in one group. In other instances, enteritis, probably due to Tyzzer's micro-organism, was the cause of death. Salmonellosis does not occur in these laboratories.

Pneumonia, probably of viral origin, occurred sporadically. Urinary retention and cystic kidneys also occurred infrequently.

Tumours, other than leukaemia, were also observed—hepatomas, subcutaneous sarcomas, and carcinomas (Table III). Hepatomas in both male and female were the most frequent. Skin sarcomas and carcinomas, some of them originating from the skin glands, were also observed in very low incidence.

It is worth while stressing again that all these tumours occurred with equal frequency in mice which had received any of the treatments.

Lesions Found in the Lungs

This section refers to the lung pathology, and this is described separately according to the treatment each group of mice received.

Controls (Group 6)

The only lung lesions observed were those due to pneumonia, probably caused by viruses.

Mice Exposed to Cigarette Smoke (Group 3)

This group showed pneumonia occasionally, with an incidence not higher than that observed in the controls. Mice which had been exposed to cigarette smoke for a long time often showed emphysema. Marked peribronchial and perivascular infiltration with lymphocytes was seen, and this independently of the presence of tumours. Hyperplastic lesions similar to those described by Leuchtenberger and Leuchtenberger (1966) were not seen even in mice which survived smoking over a period of more than 30 months.

We did observe, however, a lesion which from its characteristics could be classified as hyperplastic. This had already been described by Kotin and Falk in mice which had breathed artificial smog (see Kotin, 1966). We have observed this in one mouse out of the 200 exposed to cigarette smoke. Macroscopically it was a small hard white nodule, 1 to 2 mm. in diameter, protruding from the surface of the lung. In this group it occurred alone, but may be found more frequently with the alveologenic carcinoma which is described below (for the influenza and smoke group). Microscopically they are little different from pearls of squamous cell carcinoma, having the pathological appearance of large cells and large empty nuclei, arranged in whorls with various layers of fibrous material which stains red in the H. and E. preparations. This fibrous material is also arranged in whorls. Despite the similarity of these lesions to highly malignant lung tumours in man we have been unable to transplant them serially from one mouse to another.

Adenocarcinomas occurred in eight mice exposed to cigarette smoke. Unlike the pearls described above some of these were

serially transplantable in mice, and to date three have survived respectively for 33, 51, and 67 transplant generations.

In the mice in which they originated they appeared as white round nodules, with a diameter of up to 10 mm., protruding from the lung tissue. Metastases were found in the chest wall or parietal pleura. Microscopically they are identical to those described by Andervont (1937) and classified as alveogenic carcinomas. The cells which compose these tumours are cuboid or columnar in shape and almost uniform in size and staining reaction. They contain round or oval nuclei with loose chromatin, and nucleoli are frequently seen. The cells are often present in mitosis. The tumour cells often form a continuous sheet, which distinguishes them from the adenomas which occur spontaneously, for example, in Strong A mice. In these adenomas the cells arrange themselves so as to give the appearance of a glandular structure. Infrequently we also observed these adenomas (Special Plate, Figs. 2 and 3).

Mice Infected with Influenza Viruses (Group 1)

These mice did not show the keratinizing lesions described above. Fifteen of them (Tables IV and V) have shown adenocarcinomas identical to those described in the group of mice exposed to cigarette smoke. Eight of these tumours were transplantable, and six of them have now undergone respectively 15, 18, 26, 71, 83, and 93 transplant generations (Special Plate, Figs. 4 and 5).

TABLE IV.—Incidence of Lung Carcinomas in C57BL Mice

Treatment	Number		Lung Carcinomas	
	M	F	M	F
Influenza	342	340	12 (26, 27, 28, 29, 30 (3), 31 (2), 32, 33 (2))	3 (29, 30, 34)
Benzpyrene	100	100	1 (25)	1 (34)
Smoking	100	100	4 (10, 27, 28, 29)	4 (11, 18, 21, 27)
Influenza + benzpyrene ..	100	100	3 (21, 28, 37)	—
Influenza + smoke ..	72	83	1* (18)	2* (23, 27)
Controls	100	100	0	0

Figures in parentheses are ages of mice at detection of tumour (months).
* One other male and three other female mice had keratinizing preneoplastic lesions in the lungs.

TABLE V.—Lung Carcinomas in Relation to the Strain(s) of Influenza Virus Used

Sex	Age of Mouse (months)	Influenza Strain(s) Used
Females		
1	29	W.S.
2	30	Singapore, Lee, Swine, W.S.
3	34	Singapore
Males		
1	26	Singapore, Lee, Swine, W.S.
2	27	Swine

6	30	Lee
7	30	Swine
8	31	Singapore
9	31	Lee
10	32	Swine
11	33	Lee
12	33	Lee, Swine, W.S., Singapore

There is one lesion which is characteristic of mice infected with influenza virus and surviving the acute disease. These lesions have already been described by Kotin and Falk (1956) and by us (Harris and Negroni, 1966). They occur in almost every mouse infected with influenza viruses, and are of a hyperplastic type. Macroscopically they differ from the keratinizing lesion (or the adenocarcinomas), as they do not protrude from the lung surface, which, however, acquires irregularities. They may appear as well-defined nodules, but usually they have a very irregular edge. Microscopically they consist of cells characteristic of epithelial cells, which replace the alveolar tissue. They probably originate from the extension of the bronchial epithelium in the alveolar wall, and the arrangement of the

cells, disposed in one or two layers, seems to fill the old alveolar structure which they have replaced. When these lesions become infected pneumonia follows, with heavy infiltration of polynuclear cells. The extent of these lesions is directly proportional to the number of infections and to the dose of virus used for each infection, as may be demonstrated when the animals die or are killed, largely after recovery from the acute pneumonia caused by the influenza. However, if the animals die or are killed long after the virus infection there is no direct relation between the number and extent of the lesions and the virus dose or number of infections which the animal has received (Special Plate, Fig. 6).

Thus it appears that these lesions are progressive, though we have no evidence that they are malignant, since all attempts at transplantation have failed.

Mice Exposed to Benzpyrene (Group 2)

Only two mice have shown an adenocarcinoma as described above. The tumour arising in the female mouse was transplantable, and is now in its fifty-fifth generation.

Mice Treated with Benzpyrene and Infected with Influenza Viruses (Group 4)

These again show the typical metaplastic lesions which have already been described for mice infected with influenza viruses. These lesions occur with the same incidence. Three male mice had malignant adenocarcinomas of the lungs, all of which have been transplanted serially for 5, 10, and 20 generations respectively.

Mice Infected with Influenza Viruses and Cigarette Smoke (Group 5)

The metaplastic nodules described for mice infected with influenza virus only were also observed in animals of this group, with equal incidence (Special Plate, Fig. 7). Six have shown the squamous pearls described for mice exposed to cigarette smoke only (Special Plate, Fig. 8), and these had adenocarcinomas similar to those described in mice infected with influenza virus alone or exposed to smoke alone. One of these is in its eighty-third transplant generation.

In one instance in which this lesion occurred together with an adenocarcinoma pearls were detected in the tumour of the first transplant generation, but these were no longer found in subsequent transplantations.

Features of the Transplanted Tumours

Many of the adenocarcinomas that have been described as occurring in mice treated in these various ways grow readily when transplanted. The great majority maintain the histological features of the original tumour. Some of them, however, and mainly those originating in mice treated with benzpyrene or cigarette smoke, undergo changes. When this occurs the epithelial cells no longer form a continuous sheet; instead, they separate into clusters divided by well-developed connective tissue, which has pathological features. The tumour then acquires the appearance of a scirrhous carcinoma.

Discussion

These data indicate the potential carcinogenicity of cigarette smoke and air mixture for the lungs of experimental mice. The animals are submitted to both the liquid and the gas

phases of the smoke—an advantage over the technique of skin-painting with smoke condensate. The disadvantages from the point of view of an industry looking for a "safe" cigarette are manifold. It takes at least three years to make one test, and with the numbers of lung tumours so far produced it would be difficult to compare the carcinogenicity of different cigarette tobaccos. Moreover, as many other investigators have pointed out, the mouse lung cannot be equated histologically with the human lung, and so "degrees of carcinogenicity" derived in one system may have no validity for the other. Other tests may have to be used, though if the C57BL mice had been submitted more intensively to the smoke—for example, twice a day instead of once every two days—the lung tumour yield might well have been increased and the latent period decreased.

The smoke may not be the only cause of lung tumours, and endogenous factors such as latent viruses may be required.

It is difficult to explain the induction of lung tumours in C57BL mice by influenza viruses alone. It may be that these viruses are weakly oncogenic per se, or that there is a synergism between them and a natural but latent chemical or viral lung carcinogen in the mice, or that the influenza virus stocks were contaminated with a weakly oncogenic tumour virus for mouse lung. Polyoma would be excluded as a contaminant because the virus stocks were produced in RIF-free embryonated chicken eggs in which polyoma virus does not grow. If the third suggestion is correct, then all the virus stocks contain this virus, since lung tumours appeared in groups treated with some or all of the viruses (Table V). Moreover, since the incidence of other tumours in the influenza groups of mice was higher in the females than in the males (Table III), the hypothetical contaminant would be a specific weak lung carcinogen for males, but might produce other tumours in females. It is more probable that the second explanation is correct, and that the influenza infection "releases" a virus (such as polyoma) or a mycoplasma which is the immediate cause of the tumours.

We are currently investigating possible synergism between such chemical carcinogens as dimethylnitrosamine and cigarette smoke. If these lung tumours arose by some indirect mechanism—for example, the stimulation of a latent virus (such as polyoma)—then concomitantly one needs to postulate a general reduction in immunity which allows the "release" of virus-transformed tumour cells. It is necessary to have both steps because C57BL mice, even when newborn, are poorly responsive to large inocula of polyoma virus (Jahkola, 1965; Chang and Hildemann, 1964), though thymectomized animals (with reduced immunity) show a much higher yield of tumours. Moreover, the tumours induced in thymectomized mice by polyoma virus involve the salivary glands, kidney, bone, and hair follicles and *not* the lung.

Summary

C57BL mice subjected to breathing a cigarette smoke and air mixture for 12 minutes every other day for the greater part of their lives develop a low incidence (4%) of alveologenic carcinomas of the lung. Control animals subjected to non-specific lung damage did not develop tumours, but a group of 200 animals briefly exposed on four occasions to an aerosol of 3:4-benzopyrene developed two lung carcinomas. Attempts to influence lung tumour yield by infecting mice sequentially with influenza viruses, followed by exposure to benzopyrene or cigarette smoke and air mixture, showed that influenza viruses alone gave about 2% alveologenic carcinomas in C57BL mice—an incidence which was not exceeded in the other groups.

We acknowledge with gratitude the assistance of the Misses Ludgate, Coughlan, and Tomic and Mr. D. Stoddart in the conduct of these experiments. The apparatus was built by Mr. W. Caunt, and Mr. R. Baker has maintained it. The sections were prepared by Mrs. M. Phillips, and Mr. A. J. Pringle took the photographs.

We are grateful to the Tobacco Research Council and its director, Mr. G. F. Todd, for the provision of the cigarettes, and for advice on the smoking procedure.

Spread of Hospital Staphylococci in Healthy Families—a Study from General Practice

Report* to the M.R.C. Committee for Research in General Practice

Brit. med. J., 1967, 4, 642-644

Babies born in hospital become carriers of *Staphylococcus aureus* very early in life (Hurst, 1957). The groin and umbilical stump are usually colonized first (Jellard, 1957; Gillespie *et al.*, 1958) but soon tend to lose the organism; in the nose staphylococci settle rather later but are more firmly established, and in some maternity units over 90% of the babies are nasal carriers of *Staph. aureus* on the day they go home (Hurst, 1957). Staphylococci that colonize these infants are derived much more often from hospital sources than from the infants' own mothers (Barber *et al.*, 1953) and are often antibiotic-resistant strains known to cause outbreaks of sepsis in hospitals. Their introduction into private homes might therefore lead to nasal colonization and sepsis in other members of the family. This has sometimes happened (Wentworth *et al.*, 1958; Hurst and Grossman, 1960), but these incidents occurred at the time when *Staph. aureus* of phage type 80/81 was spreading freely and causing many outbreaks of sepsis in maternity units. Later studies suggested that babies lost their hospital-acquired staphylococci quite soon after going home (Miller *et al.*, 1962; Hurst *et al.*, 1964) and that the incidence of sepsis in their families was much the same as in control families (Oliver *et al.*, 1964); Payne *et al.* (1965) found that staphylococci which were highly communicable in hospital spread less freely in the different environment of the private home.

The general practitioner is concerned to know which of these apparently opposing views is usually correct. He would like to know the answers to three questions about the behaviour of hospital staphylococci after their introduction into otherwise healthy families: do they spread to the noses of the family as they spread to other patients in hospital; do they have any special tendency to cause septic lesions; and what precautions, if any, should the family doctor take to protect families from the potentially dangerous strains that the babies, and to a lesser extent their mothers, bring from hospital?

This survey was an attempt to answer these questions. The plan was to determine the extent to which new strains of *Staph. aureus* were introduced into families by infants and mothers returning from maternity units and spread by them to other members of the family, and to record cases of sepsis caused by these organisms. The findings were compared with the spread of presumed non-hospital staphylococci introduced by other members of the same families. Comparative studies

were also made on organisms introduced into families where a baby was born at home.

Material and Methods

A group of general practitioners—24 in Edinburgh and 25 in North-east England—filled in a questionnaire for every pregnancy booked for delivery during a period of six months. The details of each family were then analysed and families were chosen by a statistician to give equal numbers of hospital and home deliveries. The statistician also managed to ensure that the number of families chosen from the two areas was about equal, that the social status of the families in the hospital and the home group was comparable, and that there were enough schoolchildren in the families for a study of the part they played as introducers of non-hospital staphylococci.

Of the 1,780 families considered 220 were chosen, but 97 were unable to participate because of miscarriage, removal from the district, illness, and other reasons. Thus 123 families were studied and swabbed—52 in Edinburgh and 71 in North-east England. These families contained 615 persons whose noses were swabbed regularly. The swabs from 34 lodgers or occasional visitors had to be discarded because so many had moved out of the area; but, apart from this, co-operation was extremely good and at least 18 swabs were obtained from every member of all the families except five. Even in these five families there were enough swabs for satisfactory analysis.

Once a family was regarded as suitable the practitioner was notified, and with the co-operation of the family, the local authority, the health visitors, and the local bacteriological laboratory nasal swabs were taken every fortnight from all occupants of the house. Swabbing started four to six weeks before the baby was due and continued every two weeks until the baby was a year old. Septic lesions in any members of the family were reported to the doctor and swabs taken from all those with accessible pus.

One dry cotton-wool swab was used for both anterior nares of each subject. The swabs were sent to one laboratory in Edinburgh and six in North-east England. All swabs reached a laboratory within 24 hours, and most of them very much sooner than this. Swabs were plated, without preliminary enrichment, on blood-agar or milk-nutrient-agar. The plates were examined after overnight incubation at 37° C., and, when necessary, again after 24 hours at room temperature to increase pigment production. Colonies of bacteria thought to be *Staph. aureus* were tested for coagulase production by the slide technique, and a tube test was also used in doubtful cases.

All colonies of *Staph. aureus*—that is, coagulase-positive colonies—were tested for antibiotic sensitivity and were phage-typed. Some of the laboratories to which specimens were sent were not equipped to do phage-typing, and sent cultures to the typing centres that they normally used. Phage-typing methods and the criteria for identifying different strains were those specified by Blair and Williams (1961). In a few difficult cases antibiotic-sensitivity patterns were used to clarify the evidence of phage-typing.

Walker.

Report prepared by Dr. R. Blowers, Dr. K. Hodgkin, and Mr. Stanley Sklaroff (statistician).

Results

The fortnightly swabs from the noses (and lesions) of 615 persons in 123 different families were analysed. Into these families 125 babies were introduced—63 from hospital and 62 from home deliveries.

General Pattern of *Staph. aureus* Carriage

The widespread existence of *Staph. aureus* in normal families was confirmed. *Staph. aureus* was present at some time in 119 (97%) of the families and in 475 (77%) of persons. Table I shows the carriage rates for different family members. We have distinguished between "temporary" and "frequent" carriers—defined arbitrarily as those from whom *Staph. aureus* was recovered on less than and more than 20% of swabs respectively. Twenty-three per cent. of persons never carried *Staph. aureus* in their noses, 40% were temporary carriers, and 37% were frequent carriers (Table I). Gould and McKillop (1954) obtained almost identical results from a study of 520 persons.

TABLE I.—Nasal Carriage of *Staph. aureus* in Different Members of the Family

Group	No. Examined	Non-carriers		Temporary Carriers (<20% swabs positive)		Frequent Carriers (>20% swabs positive)	
		No.	%	No.	%	No.	%
Fathers ..	123	31	25	45	37	47	38
Mothers ..	123	26	21	45	37	52	42
Schoolchildren ..	132	24	18	47	36	61	46
Pre-schoolchildren ..	112	28	25	44	39	40	36
Newborn infants ..	125	31	25	63	50	31	25
All except newborn infants ..	490	109	22	181	37	200	41
All persons ..	615	140	23	244	40	231	37

There was no significant difference between the carriage rates of the various family members other than the newborn babies. In this group temporary carriage was more common than in any other family member, while frequent carriage was less common. The reason for this difference is shown in the Chart. The babies' carriage rates were high during the first few weeks after birth but declined to very low levels by the end of the year. From the eighteenth week onwards the mean carriage rate for all babies was only 7.6%. The Chart also shows great differences between the initial carriage rates of babies born in hospital and those born at home.

Staphylococcal carriage rates for the first year of life in babies born in hospital and in those born at home.

Staph. aureus Acquisition by Babies in Hospital

During the first few weeks of life *Staph. aureus* carriage was more common in babies born in hospital than in those born at home, but after 18 weeks there was no significant difference between the two groups (see Chart).

Staph. aureus was isolated from 31 (49%) of the 63 babies arriving home from hospital. Phage-typing and antibiotic sensitivity patterns suggested that in every case the strain was one that had not previously been present in the household, so we presumed, as other workers have found—for example, Barber *et al.* (1953) and Cook *et al.* (1958)—that the babies acquired the staphylococci from hospital sources. Thus there were 31 families in which hospital strains of *Staph. aureus* were introduced by a baby and had the opportunity to spread to other members of the family.

Effect of Introducing a Newborn Baby into a Family

After the three initial fortnightly swabbings had indicated the family pattern of *Staph. aureus* carriage, a new strain was reckoned to have been introduced if it had not been previously isolated from any member. The person responsible for the introduction was assumed to be the member who first yielded the new strain. Sometimes a new strain was first isolated from two members of the same family in the same fortnight; both were then counted as "introducers." Of the babies who came home after birth in hospital, 31 (49%) introduced new strains of staphylococci into their families; this was more than twice the rate of introduction by other members of the family (Table II).

TABLE II.—Introduction and Spread of New Strains of *Staph. aureus* in 123 Families

	Place of Confinement	Newborn Infants		Mothers		Members of Family other than Infants		All Persons	
		No.	%	No.	%	No.	%	No.	%
No. of individuals examined	Hospital	63		62		233		296	
	Home	62		61		257		319	
No. of individuals introducing new strain	Hospital	31	49	21	34	55	24	86	29
	Home	14*	23	15	25	61	24	75	24
No. of these individuals transmitting new strain to another member of family	Hospital	11	36	12	57	26	47	37	43
	Home	2	14	8	53	30	49	32	43

* See note in text.

Of the babies born at home 14 (23%) appear to have introduced staphylococci into the family. In two instances this was a "shared" introduction and the baby may not have been responsible. In one instance the home-born baby was admitted to hospital, and this was the probable source of the new strain. The remainder of new strains that were introduced by home-born babies probably resulted from fondling by neighbours and friends.

Of the new strains introduced by non-infant members of the family (presumably from non-hospital sources), just under half (49% and 47% in the home and the hospital groups respectively) spread to other members of the family (Table II). The 31 hospital strains introduced by infants showed no tendency to spread more freely than this; indeed, in only 11 (36%) was there any evidence from phage-typing that it had spread to other family members. These hospital strains were transmitted mainly to the mothers of the infants and to a less extent to the fathers and school-age siblings.

In 82 families one or more individuals were carrying staphylococci before the baby arrived. In 45 (56%) of these the baby picked up the family strain; Table III shows when this occurred. The percentage acquiring the original family strain

of staphylococcus was the same for babies born in hospital as for babies delivered at home.

TABLE III.—45 Babies (Hospital and Home-born) Who Picked up a Family Strain of *Staph. aureus*; Showing the Age (in Weeks) When the Pre-existing Family Strain Was First Isolated from the Baby's Nose

Age (weeks)	2	4	6	8	10	12	14	16-22	24	26-34	36
No.	14	10	8	4	3	3	1		1		1

These 45 babies include those born in hospital and those born at home.

Thus our evidence suggests that staphylococci brought home by hospital-born babies were soon replaced by family strains and that they showed, if anything, less capacity to spread within the family than staphylococci introduced from other sources.

Incidence of *Staph. aureus* Sepsis

Possible staphylococcal lesions occurred in 50 (41%) of the 123 families. Twenty-eight (23%) of the 123 families and 43 (7%) of the 615 individuals in the survey had lesions that yielded *Staph. aureus* (11 boils; 7 septic spots; 4 impetigo; 4 infected eczema; 3 septic wounds, 2 each of whitlow, conjunctivitis, and sty; 1 each of paronychia, ophthalmia neonatorum, and nappy rash; and 5 unspecified).

Phage-typing failed to show any special tendency for staphylococci from hospital to cause lesions. *In only one instance was a lesion shown to be of a similar strain to that introduced into the family by a hospital-born baby.*

Relation between Nasal Carriage and Septic Lesions

Of the 43 persons with *Staph. aureus* lesions there were 34 in whom clear-cut phage types enabled a comparison to be made with nasal strains carried by other family members. In 24 (70%) of these the strain found in the lesion was the same as that in the patient's nose; in 5 (15%) it was the same as that in the nose of another member of the family; and in 5 (15%) it was not associated with any nasal strain or with any other manifestation in the family. In families with staphylococcal lesions nasal carriage was somewhat more common than in families without lesions (45% as compared with 36%).

Nasal carriage rates in families with lesions were the same before the appearance of the lesion as after it, suggesting that lesions followed rather than caused the higher nasal carriage rates.

Discussion

This work confirms the many earlier studies on the frequency of *Staph. aureus* nasal carriage. Of the 615 persons studied in the survey 40% were classed as "temporary" carriers and another 37% as "frequent" carriers. During their first few weeks of life newborn babies had the highest carriage rates, but these quickly declined to a mean rate of 7.6% from the eighteenth week after birth onwards. The reason for this very low rate for babies once they have become established members of the family is not clear; perhaps it is due to unknown immunological mechanisms or perhaps to their having more thorough washing and fewer outside contacts than the rest of the family. Schoolchildren, who had the highest carriage rates, usually wash the least thoroughly and have many close outside contacts.

We have also confirmed the earlier reports that newborn babies acquire *Staph. aureus* much more often in hospital than at home. At the time of the first swabbings the carriage rates were 49% for babies born in hospital and 18% for babies born at home, but by the eighteenth week there was no difference between the two groups (see Chart). The rate for hospital-born babies is relatively low when compared with the rates obtained

by other workers. This could be a result of the slight delay between the time of discharge and the babies' first swabbing. It might also reflect the general trend towards lower nasal carriage rates in hospital-born babies that has been noted since 1960.

There are two possible explanations for the difference between carriage rates in the hospital and those in home-born babies: one is that staphylococci inhabiting hospitals are strains of greater inherent "communicability"; the other is that infants in hospital are exposed to a greater concentration of staphylococci and more opportunities for acquiring them. Our observations do not support the first of these possibilities; indeed, strains brought into the family by hospital-born babies spread within the family rather less often than strains introduced by other members from (presumably) non-hospital sources.

Staphylococcal lesions occurred with what seems to be the usual frequency. We detected them in 7% of our subjects; Kay (1962) reported a sepsis rate of 9% from a general practice in Manchester. But of the 34 lesions in our series from which typable strains of *Staph. aureus* were recovered, in only one had the organism been brought into the family by a hospital-born baby.

Families with staphylococcal lesions had higher nasal carriage rates than families without, and it has already been noted that the lesions appeared to be the result and not the cause of the high carriage rate.

It therefore seems that the questions we set out to study may be answered thus: (1) hospital staphylococci have no special tendency to spread in ordinary homes; (2) they have no special tendency to cause septic lesions outside hospitals; and therefore (3) the family doctor need make no special arrangements to protect families from staphylococci brought home from hospital by mothers and infants.

Summary

Noses and septic lesions of 615 persons in 123 families were swabbed every fortnight for four to six weeks before and for 52 weeks after the birth of a baby. Sixty-two babies were born at home and 63 at hospital. During the first 18 weeks of life babies born in hospital had higher *Staphylococcus aureus* carriage rates than babies born at home.

Hospital staphylococci brought home by babies were no more apt than were "domestic" strains to spread within the family or to cause septic lesions.

Staphylococcal lesions appeared to be the result rather than the cause of high nasal carriage rates within a family.

Thanks are due to the medical officers and health visitors of the following areas: Edinburgh, Newcastle, Northumberland, North Shields, Sunderland, Durham, Stockton, Middlesbrough, and Redcar.

Prolonged Survival of Liver Transplants in the Pig*

Brit. med. J., 1967, 4, 645-648

Our preliminary experience with orthotopic liver transplantation in the pig has been reported (Calne *et al.*, 1967). Out of 19 animals operated on 13 survived the procedure and six lived for a week or more. Focal necrosis of liver cells and round-cell infiltration in the portal triads of these six transplants was thought to represent evidence of a weak rejection process. One pig died after seven months from intestinal obstruction with minimal evidence of liver damage. Three pigs developed severe gastrointestinal haemorrhage due to mucosa erosions of the stomach and duodenum. We were impressed with the relatively mild rejection occurring in liver transplants in the pig, and it is the purpose of this paper to present our further

10%. This technique will be published in detail elsewhere. In brief, halothane anaesthesia is used for donor and recipient without any premedication. The donor liver is cooled by an infusion of cold physiological saline through the portal vein. When the liver has been removed from the recipient animal the blood from the inferior vena cava and portal vein is shunted to the superior vena cava via two separate shunts to the right and left jugular veins respectively (Fig. 1). The animal is systemically heparinized during this procedure. Anastomoses are performed in the following order: suprahepatic inferior

FIG. 1.—Diagram of the shunting procedure for the inferior vena cava and the portal vein in the recipient animal after removal of the liver.

experience in this field. We have added vagotomy and gastroenterostomy in an attempt to prevent the gastrointestinal haemorrhage and have related the rejection of liver transplants in the pig to transplants of kidneys and skin in this animal.

Materials and Methods

Orthotopic Liver Transplantation, Vagotomy, and Gastroduodenostomy (36 Experiments)

In the course of our experiments details of technique have been modified and the present technique, which has been used in the last 20 transplants, has had an operative mortality of

FIG. 2.—Diagram of the completed operation and anastomotic procedures; shows vagotomy, gastroduodenostomy, suprahepatic and infrahepatic vena caval anastomoses, cholecystoduodenostomy, end-to-end porto-portal anastomosis, and Carrel patch with the orifice of the coeliac artery anastomosed to the aorta.

vena cava, portal vein, coeliac artery with a Carrel patch of aorta to recipient aorta, infrahepatic inferior vena cava, cholecystoduodenostomy,† and gastroduodenostomy (Fig. 2). The vagi are divided just above the gastro-oesophageal junction. In some experiments the animal's spleen was removed; details of animals surviving four or more days are shown in Table I. The pigs were between 20 and 30 kg., and of either sex. All recipient animals were Large White pigs. Donor animals were either Large Whites or completely unrelated Landrace pigs. Details of donor and recipient are also shown in Table I. After removal of the liver from the donor animal the pig was exsanguinated, the blood collected in ACD bags and used for transfusion to the recipient. Though total blood loss was often less than 100 ml., all animals received between 1 and 2 litres of donor blood, 150 ml. of 5% sodium bicarbonate solution,

* Departments of Surgery and Pathology, University of Cambridge.

† In one animal (No. 16, Table I) choledochoduodenostomy and cholecystectomy were performed.

and 500 ml. of dextrose saline solution containing 1 g. of chloramphenicol. At the end of the operation the animals were given an infusion of 500 ml. of 5% dextrose with an additional 25 g. of glucose. Anaesthesia was maintained as light as possible, the animals breathing spontaneously. Total operative time was between two and three hours; the total ischaemic time was usually between 30 and 40 minutes, except in two experiments in which the donor animals died during the induction of anaesthesia, and the ischaemic time was in excess of an hour. After operation the animals were fasted for 24 hours and then given an ad lib. commercial pig food diet.

Kidney Transplantation (23 Experiments)

Anaesthesia was the same as for liver transplantation. Pigs were the same weight and breed. The left kidney was transplanted orthotopically, the renal vein being anastomosed to the renal vein, and the renal artery, with a Carrel patch of aorta, being anastomosed to the aorta. Usually reciprocal transplants were performed, the animals were systemically heparinized during the transplantation, and the ureters were implanted into the bladder. The period of ischaemia was usually between 15 and 30 minutes. The opposite kidney was removed.

* Common sire, different dam. † Cadaver donor. ‡ Choledochocholestomy and cholecystectomy. § Skin graft at time of liver transplant.

Skin Grafting

Split skin grafts were applied to a subcutaneous fat bed on the dorsum of the chest of the animal and pressure was used. The first inspection was on the fourth day; subsequently, daily inspections were made (Binns, 1967). Four animals were skin-grafted immediately after liver transplantation at the same operative session. An autograft was always performed at the same time as the homograft.

Pathological Studies

All animals dying were subjected to a post-mortem examination. Microscopical sections were taken from the transplanted liver, lymphoid tissue, gastrointestinal tract, kidneys, and lungs. Red blood cell grouping and cross-matching of the donor and recipient were not done. Biochemical and haematological studies were performed on 10 animals (Table II).

Results

Liver Transplantation (36 Experiments).—Four animals died during the operation and a further 12 pigs died during the first three days. The causes of these 16 early deaths varied. In some cases there was an obvious surgical error, in others no cause was determined. There was, however, no evidence of immunological rejection of the liver. Nine animals died between 7 and 81 days. Eleven animals are alive and well; four of these had skin grafts performed from the donor at the same time as the liver transplantation, and at the time of writing all four grafts were surviving between 5 and 20 days.

Renal Transplantation (23 Experiments).—Ten animals died within the first four days from a variety of causes but not from rejection of the transplants. Thirteen animals survived between 4 and 33 days (Table III).

Histological Findings

In the nine allograft livers examined microscopically more than four days after transplantation (Table I) none has shown

evidence of rejection changes similar to those described in canine liver allografts by McBride *et al.* (1962). Only slight lymphocyte, plasma cell, and other mononuclear cell infiltration was present in portal tracts and interlobular septa. Similar cells were not present in the sinusoids or around central veins (Fig. 3). Some long-term survivors showed an increase of fibrous connective tissue in the portal tracts and interlobular septa (Fig. 4). In animal No. 5 (Table I) and also in the long-term survivor of the previously reported series (Calne *et al.*, 1967) there was slight fibroelastic intimal thickening of some hepatic arteries. A variable degree of cholangitis, sometimes with abscess formation, was present in seven of the nine animals. This may have resulted from the cholecystoduodenostomy.

In contrast 12 out of 13 kidneys examined from four days onwards showed histological evidence of rejection. Lymphocytes and other mononuclear cells were present in the interstitial tissue between tubules, around glomeruli, and especially in the walls of veins and surrounding tissue. Thrombosis of arcuate and interlobular veins was conspicuous in short-term survivors (Fig. 5). In animal No. 6 there were thrombi in some glomerular capillaries. One transplant from a littermate (No. 7, Table III) showed no significant abnormalities at 12 days. The reciprocal transplant was in the longest-surviving pig (No. 6, Table III).

FIG. 3.—Section of liver transplant at eight days (animal No. 4, donor littermate, Table I); shows slight oedema and mononuclear cell infiltration of portal tract and interlobular septa. Liver cells appear normal. (H. and E. $\times 87$.)

FIG. 4.—Section of liver transplant at 81 days (animal No. 5, donor unrelated, Table I); shows slight increase of fibrous connective tissue in portal tract and around central vein. Liver cells appear normal.

Haematology and Biochemistry

The results of haematological and biochemical investigations in 10 pigs between 13 and 99 days after transplantation are shown in Table II. All animals were slightly anaemic with high total white blood cell counts. The serum bilirubin was normal in five animals and raised in the remaining four from 2 to 5.8 mg./100 ml. The S.G.O.T. was normal in three animals (normal range 5–32) and raised in the others, the highest value being 90. Alkaline phosphatase was normal in one and raised

FIG. 5.—Section of transplant kidney at five days (animal No. 4, donor littermate, Table III). Abundant mononuclear cell infiltration with thrombus in an interlobular vein. (H. and E. $\times 87$.)

in the remaining animals, the highest being 35 K.A. units. Serum electrophoresis showed reduction in the albumin in most animals and an elevated gammaglobulin in two. These investigations reveal moderate impairment of liver function in most animals, but the function was consistent with clinically healthy animals.

Discussion

The results reported here confirmed our preliminary impressions and the experiments of Terblanche *et al.* (1967), which suggested that, in the pig, rejection of the liver is a slow and sometimes remarkably mild process. There has been no instance of gastrointestinal bleeding in this series of transplants, which would suggest that vagotomy and gastroduodenostomy has been an effective prophylaxis against gastrointestinal mucosal erosions. Stuart *et al.* (1967) found a high incidence of gastrointestinal ulcers in dogs with orthotopic liver transplants and were unable to prevent ulceration by vagotomy and pyloroplasty; total gastrectomy, however, was effective. Terblanche (personal communication) also observed a high incidence of gastric haemorrhage in pigs with orthotopic liver transplants. A common complication in our experiments has been the development of cholangitis in the transplanted liver. This might be preventable by substituting a choledochoduodenostomy for the cholecystoduodenostomy. The behaviour of the transplanted liver in the pig contrasts remarkably with that of renal and skin homografts, both of which are rejected aggressively over a period similar to that observed in the dog. This reaction is fairly rapid even when donor and recipient are littermates.

The pattern of skin-graft rejection in the pig has been described by Binns (1967); an example of the histological changes is shown in Fig. 6. In untreated dogs, liver transplants may survive a little longer than kidney; nevertheless fairly typical rejection, with mononuclear cell infiltration around the portal triads and hepatic veins and hepatic cell necrosis, has been described consistently by Moore *et al.* (1960), Starzl *et al.*

(1961, 1965), McBride *et al.* (1962), and Stuart *et al.* (1967). Most dogs died from rejection of the liver within a week of transplantation. There are peculiar difficulties of liver transplantation in the dog that are not encountered in the pig and presumably would not be encountered in man. These are hepatic outflow obstruction that develops readily in the dog and the occurrence of pathogenic organisms in the portal blood of normal dogs. There are not enough data to reach any conclusions on the behaviour of livers transplanted in man without immunosuppression. In patients treated with azathioprine, corticosteroids, and antilymphocyte globulin, cellular infiltration

FIG. 6.—Section of skin homograft from unrelated donor at nine days. Shows advanced rejection of homograft epithelium (right) and underlying mononuclear cell infiltration. Normal skin on left. (H. and E. $\times 4$.)

tion in the presence of good hepatic function has been observed in four recent liver transplants (T. E. Starzl and K. A. Porter, personal communication).

The results reported here cannot be explained in terms of close relationship of donor and recipient, splenectomy, or standard immunosuppression. It will be seen from Table I that long survival occurred even when donor and recipient were of different breeds and whether or not the recipient was splenectomized. No immunosuppressive agents were given. It might be argued that the transfusion of donor blood at the time of operation could have produced immunological unresponsiveness, but Terblanche *et al.* (1967) have used indifferent non-donor blood and also obtained long-term survivors. Donor blood did not influence the survival of kidney or liver transplants in dogs (Calne *et al.*, 1966; Stuart *et al.*, 1967). The main lymphatic sac is opened in dissecting the aorta for both hepatic and renal transplants, and any possible immunosuppressive effect would presumably have been shown in the renal transplants as well as the hepatic transplants. The number of lymphocytes in the main lymphatic trunks in the pig is less than in other animals (Binns and Hall, 1966), but here again any effect of this would be expected to relate to kidney as well as liver. We are therefore compelled at present to attribute the long survival of liver transplants in the pig to some quality peculiar to the liver in this species. The mechanism of long acceptance of the liver is of theoretical interest. There are obvious possibilities that can be considered:

(1) The liver is producing a state of tolerance or immune paralysis specific for donor tissue. The preliminary observations of skin grafts placed at the same time as liver transplantation would

be consistent with such a hypothesis, but further experiments are planned to investigate this more fully.

(2) The liver is producing immunological enhancement and is being protected from immunological damage by a coating of specific blocking antibodies. So far no attempt has been made to identify enhancing antibodies in pigs with liver transplants.

(3) The liver is surviving owing to some property specifically related to the nature of liver tissue or hepatic metabolism. Certainly the liver is fully antigenic in the dog, as demonstrated by the rejection of canine livers after transplantation. In our experiments vascular endothelium, hilar lymph nodes, and whole blood are transplanted together with the liver. These tissues would be expected to be antigenic. The transplanted liver presumably continues to produce donor-type proteins and other metabolites, but there are no data available on metabolic processes of the liver that can be related to transplantation immunology.

Orthotopic liver transplants in the pig can survive and function for prolonged periods without any obvious deleterious effect on the recipient. The transplanted liver can be accepted even when the donor and recipient are from widely disparate genetic sources—that is, different porcine breeds. The surviving pigs are in good condition, though their gain in weight is not as rapid as in control animals. These observations in immunologically mature animals constitute what might be regarded as an ideal type of graft acceptance. It is certainly a stimulus for further investigation, since if the mechanism of acceptance were discovered clinical application might resolve many of the present difficulties of organ transplantation. Liver transplantation in the pig may prove to be a useful model for analysis of immunological mechanisms in transplantation biology.

Summary

Further experience of orthotopic liver transplantation in the pig showed that vagotomy plus gastroduodenostomy seemed to prevent the previous high incidence of gastrointestinal haemorrhage. Liver transplants without immunosuppression consistently survived for long periods of time in immunologically mature animals even when the donor and recipient were from widely disparate genetic sources. The behaviour of the liver is in marked contrast to kidney and skin transplants, which are rapidly rejected in similar pigs.

This work would not have been possible without the help of many of our colleagues. We are particularly indebted to Drs. M. Zakiewicz and J. Samuel. We are grateful to Mrs. M. Allen and the Department of Medical Illustration, Addenbrooke's Hospital, for the drawings, and to Dr. R. D. Keynes and the staff of the A.R.C. Institute of Animal Physiology, Babraham, for the use of their facilities and for their help.

Method for Detection of Bacteriuria Suitable for Use in General Practice

J. M. BRADLEY,* M.B., B.S.; N. CROWLEY,† M.R.C.S., L.R.C.P., F.C.PATH.

J. H. DARRELL,‡ M.B., D.C.H., M.C.PATH.

Brit. med. J., 1967, 4, 649-651

A completely satisfactory screening method for bacteriuria requiring the minimum of apparatus and bench expertise and suitable for use in general practice has still to be described. Even where laboratory facilities are readily available to general practitioners transport of the specimen without the delay which would upset the quantitative aspects of the investigation is often impossible. In addition, hospital laboratories would be unable to cope with the demands that ought to be made on them if all diagnosed urinary tract infections were adequately followed. The investigation of patients whose symptoms are less conclusive but who nevertheless may have urinary tract infections (Mond *et al.*, 1965) would add considerably to the volume of work.

A method employing disposable commercial swabs to inoculate MacConkey plates that has been developed and used for the screening of antenatal patients for significant bacteriuria at the Royal Free Hospital overcomes these disadvantages. The method has been employed without difficulty in the clinic by nursing staff, in general practice, and by medical students.

Methods

The Swab.—Pre-sterilized disposable commercially available swabs having a tightly wound cotton-wool tip 1 cm. in length were used to inoculate the medium. A machine-made swab was selected to minimize variation in size.

The Test.—Fresh preferably clean voided specimens were obtained in sterile wide-mouthed jars. In all cases specimens were plated by immersing the entire cotton-wool tip in the urine and briefly draining it against the inside of the jar before

using it to inoculate a single dried MacConkey plate. An inoculum of four parallel blocks, each comprising four strokes of the swab, was made without rotating the swab (Fig. 1).

Variation in Uptake of Urine by the Swabs.—Twenty swabs were weighed before and after charging with urine to discover the variation in absorbency.

Correlation between Swab Plating, Standard Loop Inocula, and Viable Counts.

—With the use of a technique modified from that of Miles and Misra (Cruickshank, 1965) viable counts were done on 20 specimens which were also plated by the swab method. In addition approximately 500 specimens were plated by the swab and standard loop (Guttmann and Stokes, 1963) methods. The standard loop method had been extensively compared with viable counts when it was first adopted in this laboratory for the routine culture of urine specimens six years ago (unpublished observations). Twenty-six further specimens were examined by both the standard loop and Miles and Misra methods.

Incubation.—Cultures were routinely incubated at 37° C. One hundred specimens were inoculated in duplicate by the swab method, and the duplicate plates were held at room temperature (17-22° C.). Another 26 specimens were held at 4° C. for up to 120 hours before incubation at 37° C.

Results

The Test.—By not rotating the swab during plating a slight progressive dilution was obtained. The final block inoculated

FIG. 1.—Pattern of swab inoculum

FIG. 2

FIG. 3

FIG. 4

FIG. 2.—Comparison between numbers of organisms per ml. of urine calculated by the Miles and Misra method and colony counts of the final blocks of swab platings. FIG. 3.—Comparison between numbers of organisms per ml. of urine calculated by the Miles and Misra method and colony counts of standard loop platings. FIG. 4.—Comparison between colony counts of standard loop platings and the final block of swab platings. Crosses represent infections with Gram-positive cocci, and dots infection with Gram-negative rods. The unrealistic number of specimens in the 50-500 colonies per inoculum range is due to selection of suitable specimens for comparison.

was used to read the test, and, following our usual practice, colonies were counted up to about 300 colonies per inoculum and estimated above this.

Variation in Uptake of Urine.—The weights of urine absorbed by the 20 swabs ranged between 0.1106 and 0.1441 g., with a mean of 0.1262 g. and a standard deviation of 0.0115 g. Three weighings differed from the mean by more than one standard deviation.

Correlations.—Fig. 2 shows the correlation between the swab-plating method and the viable counts done on 20 specimens. Fig. 3 shows the correlation between the standard loop plating method and the viable counts done on 26 specimens. Fig. 4 shows the correlation between the numbers of colonies in the last block of each swab plating and the standard loop method for 102 specimens collected and plated in general practice and further investigated in the hospital laboratory. Similar results were obtained with about 400 more specimens treated this way in hospital. Figs. 5 and 6 show standard loop and the corresponding swab platings. It has also been the experience of one of us (N.C.), when using similar swabs to make subcultures from liquid media, that it is practically impossible to overload the swabs, or to vary the amount of fluid absorbed, by alterations in the contact time between swab and fluid medium. The swabs are exceptionally absorbent and are fully loaded instantly.

FIG. 5.—Standard loop and corresponding swab inoculum of an insignificant mixed growth of two types of lactose-fermenting organisms.

FIG. 6.—Standard loop and corresponding swab inoculum of a significant growth.

FIG. 7.—Comparison between urine culture inoculated by swab and standard loop methods and incubated at 37° C. overnight, and inoculated by swab method and retained at room temperature (approximately 21° C.) for 48 hours. The organism was *Escherichia coli*.

Incubation.—Though in routine practice plates were incubated at 37° C. overnight, plates held at room temperature overnight were often readable, and, apart from one *Proteus* species which did not grow at room temperature, all members of the Enterobacteriaceae were easily visible at 48 hours (Fig. 7). At the cooler temperatures Gram-positive cocci required up to 72 hours to be readily visible to the untrained eye. Periods of refrigeration at 4° C. for up to 120 hours before incubation at 37° C. had no effect on the final outcome.

Interpretation.—Negative plates and those with a light or mixed growth can be confidently discarded. A heavy pure growth (greater than about 300 colonies per final block) is provisionally designated as positive. Identification and antibiotic sensitivity testing can be performed from the growth, and, when indicated clinically, treatment can be started without further investigation. An equivocal result, or a positive result without clinical indication of infection, is reinvestigated either by a second screening test or, preferably, by routine laboratory methods before instituting treatment.

Discussion

The necessity for a simple screening method for the diagnosis and follow-up of urinary tract infections in hospital and in general practice is well recognized (*Brit. med. J.*, 1965). For routine laboratory practice most authors regard semiquantitative methods, such as the standard loop methods (Hoeprich, 1960; O'Sullivan *et al.*, 1960; Guttman and Stokes, 1963), as satisfactory substitutes for potentially more accurate but time-consuming dilution methods. Non-quantitative and uninterpreted methods are no longer acceptable (Bradley and Little, 1963).

Chemical methods for detecting significant bacteriuria such as the triphenyl tetrazolium chloride test (Simmons and Williams, 1962) or the Griess nitrite test (Smith *et al.*, 1961) have been used with variable success. In the hands of its authors the former showed 95% of infections (Simmons and Williams, 1962), but in another series only 44% of infections in the 10⁵–10⁹ organisms per ml. of urine range were detected (Hinton and van der Hoeven, 1965). The latter test is apparently even less satisfactory (Kincaid-Smith *et al.*, 1964).

Whatever their accuracy chemical reactions reveal only that significant numbers of organisms are present. It is possible to obtain a positive result from a contaminated specimen, and while proper midstream specimens are desirable they are not always obtained. It is therefore important to be able to differentiate between contamination and infection. If a positive chemical test is obtained another specimen must be examined by conventional methods to identify the responsible organism (essential for proper follow-up studies) and to determine its antibiotic sensitivity pattern.

Cultural screening methods overcome these disadvantages of chemical tests. Methods such as the Leigh and Williams (1964) blotting-paper strip method, the dip-inoculum transport medium of Mackey and Sandys (1965), or the dip-slide method of Guttman and Naylor (1967) require special equipment, admittedly minor in the blotting-paper method, and expert interpretation.

As the swab-plating method is satisfactory over a relatively wide temperature range it can be used where bacteriological incubators are not available, so long as the room is reasonably temperate. Keeping the plates at room temperature is preferable to incubating them in an airing or similar warm cupboard, as the heat tolerance of members of the Enterobacteriaceae above 37° C. is far less

than at a temperature below this. Thus, from general practice, the inoculated plate can be sent to the laboratory for incubation and interpretation. If this is impossible the plates can be kept by the practitioner and only "positives" submitted for identification and sensitivity testing. Unfortunately organisms causing infections in other situations are much more fastidious in their growth requirements, and it is not possible, therefore, to use modifications of this method for other bacteriological investigations.

MacConkey plates were used because they support the growth of virtually all organisms responsible for acute urinary tract infections, and they inhibit the swarming of *Proteus* species. They can be obtained pre-poured from commercial sources and do not deteriorate during 7 to 10 days at room temperature, especially if kept in plastic bags.

Other commercial cotton-wool swabs could doubtless be used equally well, but would require initial calibration with more accurate methods. Serum-coated swabs, being water-repellent, are unsuitable.

Though 10^5 organisms per ml. of urine has come to be regarded by many as the figure below which urinary infection is not present this is not always so. As was pointed out in Kass's (1955) original paper one of the circumstances in which, with an active urinary infection, fewer organisms are found is when there is frequency of micturition. There is then insufficient incubation time in the bladder for organisms to reach 10^5 /ml. of urine. In general practice there is often "built-in" frequency, as many patients micturate immediately before leaving home. Specimens of urine obtained in these circumstances may therefore have fewer than 10^5 organisms per ml. in the presence of infection. Diuresis also significantly reduces the number of organisms (Roberts *et al.*, 1967). Other less well recognized factors, such as the excretion of inhibitory substances from the diet, may also account for fewer than 10^5 organisms per ml. in the presence of infection. These factors must be considered in reading screening tests, just as they are in the interpretation of routine cultures. It is not necessarily of any disadvantage, therefore, that accurate counts between 250 and 500 colonies per inoculum are not possible. Indeed, it is questionable whether the rigid application of accurate

methods is justifiable on such variable material. This can sometimes be undoubtedly misleading.

Summary

A cultural method for the investigation of urinary tract infections using commercially available cotton-wool swabs to inoculate MacConkey plates with freshly voided urine is described. This is simple to use, and does not necessarily require incubation at 37°C . Cultural methods have advantages over chemical screening tests, but some described previously require special equipment and thus are an added burden on laboratory preparation facilities.

We wish to acknowledge the co-operation of Dr. Betty Bass in the part of the investigation carried out in general practice and of Sister E. F. Williams, of the Gynaecological Outpatient Department at the Royal Free Hospital, and the technical assistance of Mrs. J. Wood, B.Sc.

Disposable swabs were obtained from Grahams Medical Products Ltd., St. Jude Works, Westmoor Street, London S.W.7. Pre-poured MacConkey plates can be obtained from Oxoid Ltd., London S.E.1

Blood Loss Using the Modified Two-layer Kiil Dialyser

D. B. EVANS,* M.B., M.R.C.P.; E. M. CLARKSON,† B.Sc.; J. R. CURTIS,‡ M.B., M.R.C.P.

Brit. med. J., 1967, 4, 651–653

One of the factors contributing to the anaemia of patients undergoing intermittent haemodialysis is blood loss due to blood remaining in the dialyser and extracorporeal circuit at the end of dialysis.

The present study was undertaken to determine the volume of blood remaining in the dialyser and arterial and venous blood lines at the end of dialysis, and to compare the efficiency of various techniques used to rinse back the blood in the dialyser and blood lines into the patient via the venous cannula at the end of dialysis.

Methods

Methods of Determining Volume of Blood Remaining in Dialyser and Blood Lines at End of Dialysis

A sample of the patient's blood was taken into a Sequestrene tube at the end of dialysis. Suitably diluted, this served as a standard with which to compare the haemoglobin concentration

in the wash solution obtained from the dialyser and blood lines.

When dialysis had been discontinued the blood lines and dialyser were washed through with tap-water until the washings were colourless. The dialyser was then dismantled and any blood remaining on the cuprophane membranes was washed off with tap-water. All washings were collected and the total volume was measured. After careful mixing, an aliquot from the washings was taken and stored at -15°C . or $+4^\circ\text{C}$. with the post-dialysis blood sample from the patient until the haemoglobin concentrations were estimated. Then 0.2 ml. of well-mixed whole blood from each patient was diluted to 50 ml. with 0.05% ammonia. Any intact red cells remaining in the wash solution were lysed by the addition of a small amount of

* Senior Medical Registrar, Renal Unit, Addenbrooke's Hospital, Cambridge.

‡ Lecturer in Medicine, Charing Cross Hospital Medical School, Fulham Hospital, London.

saponin. The wash solution was centrifuged and then diluted in 0.05% ammonia solution to give approximately the same haemoglobin concentration as the whole blood standard.

The haemoglobin concentration in each diluted wash solution was compared with its own whole blood standard either as oxyhaemoglobin by reading direct in a colorimeter at 540 m μ or as cyanmethaemoglobin. Conversion of the haemoglobin to cyanmethaemoglobin was found to be necessary only when bloods and wash solutions had been stored at 4° C. for more than 24 hours. The mean difference in 20 estimations carried out by the two methods in parallel was 0.7% (S.D. 2.6).

The haemoglobin remaining in the dialyser and blood lines at the end of dialysis was expressed as millilitres of the patient's blood.

Dialysis Techniques

Permanent Teflon-Silastic arteriovenous shunts are used. A single pass system is employed with modified two-layer Kiil dialysers and cuprophane membrane (PT 150). Initially the dialysis fluid was not heated, and this necessitated long venous blood lines so that the patient's blood could be rewarmed before being returned from the dialyser to the venous cannula. The dialysis fluid is now heated to 37° C. so that blood rewarming is no longer necessary and shorter venous lines can be used.

Wash-back Techniques at End of Dialysis

(1) During the period when blood rewarming was employed and long venous blood lines were used a comparison was made between two methods of washing back the blood at the end of dialysis. In one technique, at the end of dialysis the arterial blood line was clamped and cut near the patient's arterial cannula and then 500 ml. of 0.9% saline was infused into the arterial line. The dialyser in this technique was kept in the horizontal position throughout. The dialysis flow was continued at 500 ml./minute throughout. The other technique was similar except that the dialyser was tilted at an angle of 45°, with the arterial end raised during the last half-hour of dialysis. Each technique was carried out on 10 occasions in the same dialyser and on nine occasions in another dialyser. The volume of blood remaining in the dialyser and extracorporeal circuit was determined on each occasion.

(2) After the first study the technique of dialysis was changed and warm dialysis fluid was used so that rewarming of the blood was unnecessary. As a result of this it was possible to use shorter venous lines. After the introduction of these modifications two other wash-back techniques were compared. In one the dialyser was tilted at 45°, with the arterial end raised for the last half-hour of dialysis, and then at the end of dialysis 1,000 ml. of 0.9% saline was infused into the arterial line. In the other method the dialyser was tipped vertically with the arterial end uppermost during the last half-hour of dialysis and then at the end of dialysis 1,000 ml. of 0.9% saline was infused into the arterial line. With both of these techniques the dialysis flow was continued at 500 ml./minute throughout. Each technique was employed on nine occasions with the same dialyser, the volume of blood remaining in the dialyser and extracorporeal circuit being measured on each occasion.

Use of Most Efficient Wash-back Technique in Different Kiil Dialysers

The most efficient wash-back technique proved to be the one which included vertical tipping of the dialyser during the last half-hour of dialysis together with a rinse of 1,000 ml. of 0.9% saline at the end of dialysis. In the final part of the study this technique was used in nine different Kiil dialysers and the residual blood volumes were compared.

Results

(a) *Use of Long Blood Lines (Blood Rewarmed) + 500 ml. 0.9% Saline and Dialyser Horizontal or Tilted 45°.*—Table I shows volumes of blood remaining in the dialysers and blood lines with the two techniques. Twenty experiments were carried out with dialyser S II and 18 with dialyser S III. The volume of blood remaining when the dialysers were tilted during the last half-hour of dialysis tended to be smaller than when they were kept horizontal, but the difference between the means was not significant.

TABLE I

S II Dialyser Volume of Blood (ml.)		S III Dialyser Volume of Blood (ml.)	
45°	Horizontal	45°	Horizontal
75	60	71	54.5
74	117.5	84	112.5
43	140	78	97
99	122	68	107
83.5	278	90	118

Mean = 12.6. S.D. = 11.5. Range 0.4-31.3.

Discussion

Priming with blood is unnecessary with the Kiil dialyser, but relatively large volumes of blood may be left in the dialyser and extracorporeal circuit at the end of dialysis. This loss of blood with each dialysis contributes to the anaemia of patients on intermittent haemodialysis.

Various techniques have been described to wash the blood remaining in the dialyser back into the patient via the venous cannula at the end of dialysis.

Cole *et al.* (1962), using Kiil dialysers, stated that if the dialyser was kept in the horizontal position at the end of dialysis and an attempt made to rinse the blood back with saline most of the red cells remained behind while mainly plasma was washed back into the patient. It was estimated that probably more than 100 ml. of packed cells was left behind in the dialyser at the end of each dialysis. If, however, the

dialyser was tipped vertically, with the blood flowing downwards during the last 10 minutes of dialysis, and was then rinsed with saline, Cole *et al.* (1962) estimated that the loss of red cells was reduced by a half to one-quarter. This change in the wash-back technique resulted in a reduction in average transfusion requirements from 5 units/month to 2.5 units/month.

Cole *et al.* (1963), again using Kiil dialysers, made some measurements of the volume of blood remaining in the dialyser and extracorporeal circuit by means of two wash-back techniques. In the first the dialyser was kept in the horizontal position throughout and 400 ml. of saline was used to rinse back the blood. With this technique the mean volume of blood remaining was 140 ml. (32 determinations). The second wash-back technique used was rather complicated and involved elevation of the arterial end of the dialyser by 15 in. (38 cm.) during the last half-hour of dialysis. In addition the dialysate flow was changed from countercurrent to concurrent by switching the dialysate tubes to opposite ends of the dialyser and increasing the dialysate flow from 500 ml./minute to 3–4 litres/minute. The dialyser was then rinsed with saline, 100-ml. aliquots being run in via the arterial blood line with the dialysate flow temporarily stopped. The dialysate flow was then increased again to 3–4 litres/minute until blood flow ceased. This process was repeated until a total of 400 ml. of saline had been used to rinse the dialyser. With this technique the mean volume of blood remaining in the dialyser was very significantly reduced to 35 ml. (92 determinations).

Johnson *et al.* (1966), also using Kiil dialysers, rinsed the dialyser at the end of dialysis with 150–250 ml. of saline and found an average of 20 ml. of blood left behind. These workers do not state whether the dialyser was tilted in any way towards the end of dialysis.

In the present study we have confirmed that large volumes of blood may remain in the Kiil dialyser at the end of dialysis. Various wash-back techniques are compared, the most satisfactory of which involves tipping the dialyser vertically, with the blood flowing downwards, during the last half-hour of dialysis and rinsing with 1 litre of saline at the end of dialysis.

The mean volume of blood remaining when this technique was employed in nine experiments with the same dialyser was 16.9 ml. This method was then used in nine different dialysers, the mean volume of blood in the nine dialysers being 12.6 ml. Another factor contributing to these results is the improvement in the quality of the dialysers now produced by various manufacturers. It is notable that in five dialysers, four of which were produced in the last year, blood losses with the above wash-back technique were extremely small, with a mean of 3.1 ml. (range 0.4–6.4 ml.). It is also essential to be able to tip the Kiil dialyser vertically towards the end of dialysis, and trolleys designed to hold these dialysers must incorporate this facility.

Summary

Large volumes of blood may remain in the Kiil dialyser and extracorporeal circuit at the end of dialysis if inefficient wash-back techniques are employed and will contribute to the anaemia of patients on intermittent haemodialysis.

Several wash-back techniques were tried, and in three of these the mean volume of blood remaining in the Kiil dialyser and extracorporeal circuit varied from 52.9 to 143 ml.

The most efficient method used involves tipping the dialyser vertically so that the blood flows from the top downwards during the last half-hour of dialysis and rinsing with 1 litre of 0.9% saline at the end of dialysis.

This method was used with nine different Kiil dialysers. The mean volume of blood remaining in the dialyser and extracorporeal circuit was 12.6 ml.

We are indebted to Sister J. M. Storey and the staff of the Haemodialysis Unit, Fulham Hospital, for assistance in carrying out this study.

Traveller's Diarrhoea: a Survey of Symptoms, Occurrence, and Possible Prophylaxis

ANTHONY C. TURNER,* M.R.C.S., L.R.C.P., D.OBST.R.C.O.G.

Brit. med. J., 1967, 4, 653–654

Traveller's diarrhoea, described by Gordon (1965) as a notorious world-wide illness lasting one to three days, presents a precipitous onset of loose stools and variable symptoms, including nausea, vomiting, abdominal cramps, etc. It often occurs sporadically as isolated cases, though epidemics occur within families or groups of travellers of all ages. The incidence varies according to geographical locations (Kean and Waters, 1958).

Previous studies (bacteriological and prophylactic) have been undertaken (Lie Kian Joe, 1956; Kean and Waters, 1959; Varela *et al.*, 1959; Kean *et al.*, 1962; Nelson *et al.*, 1962) without producing definite conclusions regarding the value of prophylactics or the causal relation between diarrhoea and considered pathogens.

Dr. D. J. Cussen attended the U.K. Olympic teams in Rome 1960 and gave one tablet of Streptotriad twice daily; other

teams had an appreciable amount of diarrhoea, but no cases occurred in the U.K. teams. As neomycin is widely used in gut infections, it was decided to undertake an extensive controlled prophylactic trial comparing Streptotriad, a neomycin-sulphonamides compound, and a placebo in B.O.A.C. personnel and their families going abroad.

Method

Tablets A, B, and C were randomly allocated to 1,383 subjects (see Table), except that complete families were given the same tablet to avoid interchange of medication. Anyone with known drug allergy was excluded. Participants were told to maintain their usual standards of food hygiene and received instructions regarding dosage and duration of medication as follows: one tablet twice daily for the first two weeks while away, one tablet daily for the third week, then stop. Children under 12 years were given half this dosage. Two sealed letters indicating the

* Senior Overseas Staff Medical Officer, Air Corporations Joint Medical Service, London Airport, Hounslow, Middlesex.

identity of the tablets were given to each participant—one addressed to the B.O.A.C. appointed doctor at the visited territory and one to the subject's local doctor. One of these was to be given to the appropriate doctor if diarrhoea developed during the overseas visit or on return home. A questionnaire was completed by each patient, and the data were coded and analysed by means of a punch-card system.

There were three males for every two females; 10% were 19 years or less, 20% 50 years and over, and the remainder 20 to 49.

Treatment Groups	
Group A. Inert control	385
Group B. Neomycin-sulphonamides (each tablet containing neomycin sulphate 200 mg., sulphadimidine 100 mg., sulphadiazine 100 mg., and sulphathiazole 100 mg.) ...	355
Group C. Streptotriad (each tablet containing streptomycin sulphate 65 mg., sulphadimidine 100 mg., sulphadiazine 100 mg., and sulphathiazole 100 mg.) ...	364
Excluded from analysis	279*
	1,383

* 258 failed to comply, 21 stopped tablets within five days because of reaction or side-effects (details see below).

Results

Just over 1,100 completed the survey with practically equal numbers in each treatment group. Streptotriad was found to be beneficial in reducing the diarrhoea and associated symptoms, while neomycin-sulphonamides, though reducing the associated symptoms, did not affect the diarrhoea.

The incidence of diarrhoea was significantly less in the Streptotriad group, and was confirmed by statistical analysis ($\chi^2=11.86$, $\eta=4$, $P<0.02$). Though the incidence of diarrhoea was slightly higher with neomycin-sulphonamides than with placebo there was no statistical difference between them.

Among those in whom the length of attack was known, it lasted one day in 33.8% and no more than three days in 75.2%. This duration confirms Gordon's (1965) description of traveller's diarrhoea. The participants who had three or more stools on the third day were significantly fewer in the Streptotriad group.

The results confirm the description of Gordon in that out of 186 patients having diarrhoea, 64 had abdominal pain, 39 felt tired, 27 lost appetite, 27 had nausea, and 26 vomited. Few patients thought they were febrile. The total incidence of associated symptoms was significantly and statistically less with both active tablets than with the placebo.

Other common symptoms of travellers overseas were also noted: constipation, colds, sore throats, and mouth ulcers. Approximately 10% had constipation; this was mostly ascribed to taking the tablets, but the incidence was slightly higher among those receiving the placebo. The constipation was almost certainly due to the upset of the circadian physiological rhythms associated with long-distance flights.

The incidence of diarrhoea related to territory emerges as follows: Africa 25.9%; Middle East 23.5%; South Europe 16.9%; North and Central Europe 15.6%; Asia (including India and Pakistan) 15.4%; South America and Caribbean 12.6%; Australasia 11.3%; North America 7.7%. The one surprising result is the low incidence in India and Pakistan.

Adverse Reactions.—Twenty-five persons stopped taking the tablets because of suspected reactions, 21 within five days and four within 10 days. Fourteen were thought to be unconnected with medication (seven were placebo reactors). Of the 11 prob-

ably connected, most occurred in the neomycin-sulphonamides group; five developed rashes, and six developed diarrhoea which cleared after stopping the tablets. There were two reactions reported with Streptotriad,* but these were thought to be unconnected.

Discussion

Though traveller's diarrhoea is not a serious illness it can be incapacitating, especially to the business man carrying out extensive air travel within a tight schedule. A three-day stay in an overseas capital to collect the year's export orders could be completely lost. The plan, therefore, was to try to find a prophylactic agent which would be effective in reducing the incidence of this complaint and at the same time to obtain further information regarding incidence, associated symptoms, and geographical distribution.

Since the termination of the survey, frequent requests have been received for further supplies of tablet C (Streptotriad).

In view of the finding by Kean and Waters (1958) that 63% of cases of diarrhoea occur during the first week, it might be advisable to double the suggested dosage in the first week only.

Summary

This report describes a comparison of Streptotriad with neomycin-trisulphonamides and a placebo in the prophylaxis of traveller's diarrhoea involving about 1,100 B.O.A.C. personnel and families taking trips abroad. Medication was randomly allocated and given for three weeks, one tablet twice daily for the first two weeks while away and one daily for the third week. Children under 12 were given half dosage. The commonest places of occurrence were Africa (25.9%) and the Middle East (23.5%).

Streptotriad was statistically beneficial in reducing both diarrhoea and associated symptoms. Neomycin-trisulphonamides was statistically beneficial in reducing symptoms, but not diarrhoea; abdominal pain was the commonest associated symptom: 75% had a duration of three days or less. Adverse reactions were practically nil with Streptotriad, which was by far the most popular medication as noted by the number of subsequent requests.

In view of Kean's work it might be worth considering whether the dosage of Streptotriad should not be doubled during the first week.

Thanks are due to May & Baker Ltd., who provided the tablets and printed material; to Professor A. W. Woodruff for his frequent advice; and to Dr. J. Graham Taylor, Director Medical Services, Air Corporations Joint Medical Service, for permission to publish.

Urinary Leucocyte Excretion in Hypertension in Pregnancy

M. A. CHADD,*§ M.B., B.CH., D.C.H.; D. MICHAEL HUMPHREYS,* M.B., CH.B.
H. M. LEATHER,† M.D., M.R.C.P.; S. A. WILLS,‡ A.I.M.L.T.

Brit. med. J., 1967, 4, 655-656

Little (1966) showed that urinary white cell excretion rates were normal—that is, less than 200,000 per hour—in 95% of pregnant women free from bacteriuria and in only 28% with bacteriuria. Kincaid-Smith and Bullen (1965) found persistently raised urinary white cell excretion rates, despite successful treatment of bacteriuria, in pregnant women who were subsequently found to have established renal disease. Cross and Leather (1965) reported abnormal white cell excretion rates in hypertension in pregnancy irrespective of the clinical cause of the hypertension. The present study has been made to determine how long after delivery this abnormal leucocyte excretion persists, what relation it bears to continued hypertension in the post-partum period, and in particular whether it is associated with pyelonephritis.

The series includes 61 patients with hypertension in pregnancy and a further control group of 54 normotensive pregnant subjects. The effect on the leucocyte excretion of a course of ampicillin in 26 of the hypertensive patients and of lowering the blood pressure with hypotensive drugs in a further 15 patients was determined.

Material and Methods

Control subjects were healthy normotensive pregnant women from 16 to 38 weeks of gestation, with no history of urinary tract infection and in whom the urine was sterile. The hypertensive patients' period of gestation ranged from 16 to 36 weeks. For the purpose of this study hypertension was defined as a diastolic blood pressure of 90 mm. Hg or more, and at least two such readings were required before admission to the series. Urinary leucocyte excretion before and after prednisolone provocation was determined by the method of Houghton and Pears (1957) with the modification that three urine specimens were collected at 90-minute intervals after prednisolone. To avoid contamination of the urine, specimens were collected by the method of Leather and Hutchings (1960). Resting leucocyte excretion levels below 200,000 cells/hour were regarded as normal (Little, 1966). A prednisolone provocation test was regarded as positive when in one of the post-prednisolone urine specimens the leucocyte excretion rate was double that of the control period and also exceeded 300,000 cells/hour (Leather, Wills, and Gault, 1963). Urine was cultured on blood agar and MacConkey's media. In all cases a colony count was performed with the serial dilution technique. Urine studies were repeated throughout pregnancy and at intervals up to one year after delivery. Excretion urography was carried out in the hypertensive patients two months or more after delivery.

Results

Control Subjects.—The 54 normotensive patients were aged 16-43 years, and 26 were primiparae. In 16 resting leucocyte excretion was abnormal, and a further 15 became abnormal

after prednisolone. The urine was infected (>100,000 org./ml.) in six, of whom five showed abnormal leucocyte excretion before or after prednisolone. Excretion rates were more often abnormal in late than in early pregnancy: thus 15 out of 22 pregnancies of more than 30 weeks' gestation were abnormal, compared with 16 out of 32 pregnancies of less than 30 weeks. Neither age nor parity seemed to influence the abnormal rates.

Hypertensive Subjects.—The 61 hypertensive patients were aged 19-43 years; 21 were primiparae. In 28 the resting leucocyte excretion was abnormal and in a further 20 it became abnormal after prednisolone. Thus only 13 out of the 61 were entirely normal. In all cases leucocyte excretion was estimated at least twice during the pregnancy. In nearly all cases these repeated results were in the same range as the initial count. The urine was infected in eight, of whom four showed abnormal leucocyte excretion. In contrast to the control subjects, leucocyte excretion was not raised more often late in pregnancy; thus all 13 before 30 weeks were abnormal, compared with 35 out of 48 after 30 weeks.

Effect of Blood Pressure Control on Leucocyte Excretion.—Of the hypertensive patients 35 were currently in a study to determine the effect of control of hypertension in pregnancy; 20 of these received no hypotensive agents and in 15 the blood pressure levels were controlled with hypotensive drugs. Leucocyte excretion was studied before and after a period of observation (average 67 days). Of the 20 controls, 17 were abnormal at the first count and 18 subsequently; of the 15 treated cases, 13 were abnormal at first and 11 subsequently. There was therefore no evidence that control of hypertension influenced the leucocyte excretion rate (Table I).

TABLE I.—*Urinary Leucocyte Excretion During and After Pregnancy in Hypertensive Patients*

Group	Abnormal White Cell Excretion			
	During Pregnancy		Post-partum	
	No. Studied	No. Abnormal	No. Studied	No. Abnormal
Untreated hypertensives ..	20	18	15	4
Treated hypertensives ..	15	11	14	10
Ampicillin-treated ..	26	19	19	10

Effect of Antibiotics on Leucocyte Excretion.—Twenty-six were given a course of ampicillin (average duration 17 days), 19 of these having abnormal counts initially. After ampicillin therapy all 19 patients remained abnormal. There was no evidence that antibiotic therapy affected the abnormal excretion rate (Table I).

Urinary Leucocyte Excretion After Delivery.—In 48 out of 61 hypertensive patients urinary leucocyte excretion was abnormal during pregnancy. Of the 48 who were restudied up to 12 months post-partum, 24 were abnormal and 24 were in the normal range; the remaining 13 failed to attend (Table I).

Urographic Findings.—Excretion urography was performed on 44 of the hypertensive patients: 27 were normal or showed non-pathological variations; 5 showed post-pregnancy changes with dilatation of the renal pelvis and dilatation and tortuosity of the ureters, and 12 were definitely abnormal and included

§ Present address: Department of Child Health, United Cardiff Hospitals.

pyelonephritis (5 cases), renal ischaemia (2 cases), unilateral renal atrophy (2 cases), reflux hydroureter (2 cases), and polycystic disease (1 case).

Relation Between Urographic Findings and Abnormal Leucocyte Excretion.—White cell excretion before and after delivery was known in all patients who were radiographed. Abnormal excretion persisted after delivery in roughly the same proportion in those with normal x-ray picture, post-pregnancy change, or pathological change (Table II).

TABLE II.—*Relation Between Radiological Findings and Abnormal Leucocyte Excretion*

	No.	Abnormal Excretion	
		Ante-partum	Post-partum
Normal x-ray picture ..	27	20	12
Post-pregnancy change ..	5	5	2
Pathological change ..	12	11	6

Relation Between Urographic Findings, Persistent Hypertension, and Post-partum Urinary Leucocyte Excretion.—In all 44 patients in whom excretion urography was performed leucocyte excretion was measured after delivery. In 23 it returned to normal and in 21 it remained abnormal. The incidence of normal or abnormal urographic findings and of persistent hypertension was similar in both groups (Table III).

TABLE III.—*Relation Between Urographic Findings, Persistent Hypertension, and Post-partum Urinary Leucocyte Excretion*

Urinary Leucocyte Excretion	No.	Urography		Hypertensive Post-partum
		Negative	Positive	
Returned to normal ..	23	15	8	11
Remained abnormal ..	21	12	9	10

Discussion

Both normotensive and hypertensive non-infected non-pregnant women give urinary leucocyte excretion rates within the accepted range of normal (Pears and Houghton, 1959; Hutt *et al.*, 1961), and Little (1966) reported normal excretion rates in a very high proportion of pregnant women without bacteriuria. Cross and Leather (1965) reported raised urinary leucocyte excretion before or after prednisolone provocation in 29 out of 31 pregnancies complicated by hypertension but without bacteriuria.

In the present series of 115 pregnant women, urinary white cell excretion was abnormal in more than 50% of apparently normal subjects and in 80% of hypertensive patients. There was no evidence from association with symptoms of

urinary tract infection, positive urine cultures, or response to antibiotics that it was necessarily a manifestation of infection in the urinary tract. In the hypertensive group it was not modified by the use of hypotensive drugs and had no clear association with the persistence or otherwise of hypertension after pregnancy. Finally, there was no evidence from the subsequent urographic findings that it bore any relation to established renal disease as assessed by radiology.

The reason for the increased urinary leucocyte excretion in pregnancy remains therefore unexplained. It is possible that it represents some form of vascular response to the pregnancy itself, since there was evidence in some of the groups studied that the number of abnormal tests increased with advancing gestation and that in some of the cases it returned to normal after pregnancy. However, its value as evidence of infection or of anatomical abnormality of the urinary tract appears to be negligible.

Summary

Urinary leucocyte excretion was abnormal before or after prednisolone provocation in 31 out of 54 normotensive pregnant subjects and 48 out of 61 hypertensive pregnant subjects. In the hypertensive group treatment with antibiotics or hypotensive agents failed to alter the abnormal leucocyte excretion, which in nearly half the cases returned spontaneously to normal after delivery. There was no evidence that abnormal leucocyte excretion was a manifestation of pyelonephritis or that it bore any relation to the persistence or otherwise of hypertension after delivery.

We wish to thank the obstetricians of the Plymouth General Hospital—Messrs. J. G. Dumoulin, G. M. Davidson, and I. Cunningham—for ready access to patients under their care and for encouragement and help during this study. We are grateful to Dr. H. T. ApSimon for reviewing the radiographs. Three of us (M. A. C., D. M. H., and S. A. W.) were in receipt of research grants from the Research Committee of the South-western Regional Hospital Board.

Scleroderma Heart Disease

E. FLETCHER,* M.D., F.R.C.P.; P. MORTON,† M.D., M.R.C.P.ED.

Brit. med. J., 1967, 4, 657-658

Generalized progressive scleroderma is characterized by visceral involvement concerning which there are many important reviews in the literature (Beigelman *et al.*, 1953; Leinwand *et al.*, 1954; Oram and Stokes, 1961). Weiss *et al.* (1943) firmly established scleroderma heart disease as a clinical entity. Oram and Stokes (1961) summarized the cardiac manifestations, which include myocardial failure, pericarditis, chronic cor pulmonale, various arrhythmias, and incidental findings such as cardiomegaly, cardiac murmurs, and electrocardiographic anomalies.

The clinical, electrocardiographic, and necropsy findings in two cases with cardiac involvement are reported here. One of us (E.F.) has already published two additional cases with pathological findings in the heart (Roesler and Fletcher, 1963, Figs. 46 and 47).

Case 1

A woman aged 50 had had joint pains and stiffness for about 10 years. At the time the E.C.G. shown in Fig. 1 was recorded she had extensive scleroderma involving the limbs and trunk. She complained of shortness of breath. The heart sounds were normal and there was a basal systolic murmur. Blood pressure was 102/70 mm. Hg, serum calcium 10 mg./100 ml., and serum potassium 4.6 mEq/l. Radiological examination showed extensive soft-tissue calcinosis. X-ray examination of the chest showed a normal heart shadow and extensive fibrosis of the lower lobes of the lungs. Three months after the electrocardiogram was recorded she developed bronchopneumonia and died. No digitalis had been given at any time.

At necropsy the heart weighed 400 g. Both ventricles were hypertrophied. Microscopical sections of the ventricular myocardium showed areas of small haemorrhages and fibrosis with perivascular

FIG. 1.—Case 1. Scleroderma heart disease. Abnormal S-T segment and T-wave changes.

infiltration by plasma cells and eosinophils. The coronary arteries showed minimal atheroma with no evidence of occlusion of any coronary vessel of significant size. The valves were all normal. Both lungs showed extensive fibrosis.

In Fig. 1 the limb leads show abnormal low voltage, no deflection exceeding 5 mm. in amplitude. There is sinus rhythm, rate 88 a minute. The mean QRS axis is deviated towards the right, with a deep S deflection in lead I and a late R deflection in lead aVR. The P-R interval measures 0.15 sec. and the QRS interval 0.09 sec. The Q-T interval measures 0.37 sec., which is the upper limit of normal for the heart rate. The S-T segments are abnormally depressed in leads II, III, and aVF, with reciprocal slight

elevation in leads I, aVR, and aVL. The chest leads show low QRS voltage in lead V1 adjacent to the right ventricle, and also in lead V6 adjacent to the left ventricle. The S-T segments are displaced downwards in leads V1, V2, and V6, and the T waves are negative in leads V3 and V4. The T wave in lead V5 is abnormal in shape.

Comment.—The abnormal S-T segment and T-wave changes indicate myocardial impairment due to the extensive infiltration of the myocardium found at necropsy. The biventricular hypertrophy resulted likely from compensation for the loss of myocardial fibres from progressive fibrosis. The abnormal low QRS voltage recorded in spite of the hypertrophy may reflect changes in the conduction properties of the lungs associated with pulmonary fibrosis. The R deflection in lead V1 is relatively high in amplitude compared with the S deflection, which may be due to right ventricular hypertrophy noted at necropsy. In leads V2, V3, and V4 the QRS voltage is normal or increased, as these leads are adjacent to the "bare area" of the heart with little intervening abnormal lung tissue. The right axis deviation appears to reflect right heart strain associated with extensive pulmonary disease.

Case 2

This patient began to develop multiple joint pains at about the age of 30. They were insidious and progressive, and two years after their onset she had a medical examination in hospital. The only abnormality discovered was a raised blood sedimentation rate. An electrocardiogram was reported as normal. She was next seen in hospital at the age of 40, when she was found to have extensive scleroderma. In the intervening years she had had intensified joint pains and stiffness. She complained of shortness of breath and dysphagia. The facial structures were shrunken and she had a "small mouth." There were flexion deformities of the limbs due to scleroderma. The heart sounds were normal and there was a basal systolic murmur. Blood pressure was 110/70 mm. Hg, serum calcium 10 mg./100 ml., and blood urea 40 mg./100 ml. She died five months after the electrocardiogram (Fig. 2) was recorded. No digitalis had been given.

At necropsy there was a pericardial effusion of blood-stained fluid. The coronary arteries and valves were normal. The heart weighed 370 g. The right ventricle measured 0.7 cm. in thickness and the left ventricle 1.2 cm. Microscopical sections of the myocardium showed diffuse interstitial fibrosis. Both lungs also showed fibrotic changes. The kidneys were normal.

The E.C.G. in Fig. 2 shows sinus rhythm, rate 86 per minute, P-R interval 0.16 sec., QRS interval 0.08 sec. The QRS voltage is normal and the mean QRS axis is normally directed. The S-T segments are abnormally depressed in leads I, II, aVL, and V4 to V7. The high-amplitude R deflection in lead Ve measuring 6 mm. is

FIG. 2.—Case 2. Scleroderma heart disease. Abnormal S-T segment changes.

* Physician in Charge, Cardiovascular Unit, Belfast City Hospital, Belfast 9.

† Physician, Cardiovascular Unit, Belfast City Hospital, Belfast 9.

greater than the S deflection, and this may reflect right ventricular hypertrophy, as this lead is located at the xiphisternum.

Comment.—The electrocardiogram was recorded five months before death, so that close correlation with the necropsy findings has less meaning. Nevertheless, it is reasonable to assume that the abnormal S-T segment changes reflect myocardial impairment due to the diffuse myocardial fibrosis found at necropsy.

Discussion

These two patients had primary myocardial infiltration and fibrosis associated with advanced scleroderma. They complained of breathlessness, but assessment of this symptom is difficult in view of the pulmonary fibrosis and restriction of respiratory effort in extensive scleroderma. Radiological and auscultatory findings were not particularly helpful. The electrocardiogram alone afforded objective evidence of primary myocardial involvement, as noted in the above comments. The abnormal findings were confined chiefly to S-T segment and T-wave changes, indicating abnormal repolarization of the ventricular myocardium on the basis of extensive myocardial impairment supported by necropsy findings. Windesheim and Parkin (1958) reviewed the electrocardiographic findings in 27 similar cases, of which three showed low QRS voltage and T-wave changes similar to those described above. Pulmonary involvement or metabolic abnormalities in scleroderma may also

produce secondary electrocardiographic anomalies, as noted in the interpretations. Neither patient had hypertension to complicate the electrocardiographic findings. The cause of death was probably not related directly to the cardiac abnormality in either case.

Summary

Two cases of generalized progressive scleroderma are described with electrocardiographic and necropsy findings. Cardiac symptoms may be masked by pulmonary involvement. The electrocardiogram gave the most useful objective evidence of the primary myocardial infiltration, confirmed at necropsy, when correlated with the clinical findings. The S-T segment and T-wave changes, however, are non-specific in character, and this requires to be taken into account in generalized scleroderma, which may also be associated with renal hypertension and metabolic imbalance.

Medical Memoranda

Fatal Hypercalcaemia Complicating Carcinoma of Breast, Resistant to Cortisone and Phosphate Administration

Brit. med. J., 1967, 4, 658-659

One in three patients suffering from carcinoma of the breast metastases five years after the menopause may be expected to achieve temporary suppression of these metastases by the use of oestrogens (Taylor, 1956). This therapy is often chosen first in the post-menopausal woman, as it causes less endocrine upset than either androgens or cortisone. The effects of oestrogen therapy are always carefully observed in each patient, as some metastases in the elderly are oestrogen-dependent and flare up on treatment. One of the methods used to detect this dependence has been the increased urinary calcium excretion which occurs (Emerson and Jessiman, 1956), and on occasion hypercalcaemia (Kennedy, Nathanson, Tibbetts, and Aub, 1955). Several authors mention that this complication of therapy may be fatal (Herrmann, Kirsten, and Krakauer, 1949), and eight cases have been recorded (Kleinfeld, 1962). We had the opportunity of observing and treating a similar patient while she was on a fixed dietary intake of calcium in preparation for other metabolic measurements.

CASE HISTORY

A 66-year-old widow was admitted to hospital for investigation of a three-month history of tiredness, nose bleeds, and nodules in the skin. On questioning she admitted to a mass in the breast which had been present for at least eight years to her recollection.

On examination she was pale, there were multiple skin secondaries stemming from a hard fixed mass in the right breast which had not ulcerated, and bruises on the back and over both knees. The liver was enlarged 3 cm. below the right costal margin. There was no

bone tenderness. Blood pressure was 155/90 mm. Hg. Further systemic examination was normal.

Investigations.—Haemoglobin 6.8 g./100 ml.; W.B.C. 4,600/cu. mm., with 5% myelocytes and 25 nucleated red cells/100 W.B.C.s; platelet count 13,000/cu. mm. Radiographs of chest and spine showed diffuse osteolytic metastatic infiltration involving the ribs, dorsal and lumbar spine, sacrum, and pelvic region. Lung fields were clear. Serum proteins 6.3 g./100 ml., electrophoretic pattern normal. Serum alkaline phosphatase 6.6 K.A. units/100 ml. (normal 3-14) (King and Armstrong, 1934). Serum alanine aminotransferase 15 units/ml. (normal 0-25 units) (Reitman and Frankel, 1957). Plasma calcium 9.7 mg./100 ml. by flame photometry (MacIntyre, 1961). Plasma inorganic phosphorus 3.3 mg./100 ml. (Fiske and Subbarow, 1925). Na 143, K 4.3, HCO₃ 20 mEq/litre. Blood urea 42 mg./100 ml. The 24-hour urinary excretion of calcium on admission was 36.5 mg. on a ward diet. Electrocardiogram was normal. Biopsy of skin nodules showed a spheroidal-cell carcinoma infiltrating the dermis and fat.

She was transfused with 4 pints (2.3 litres) of blood, one of the skin nodules was biopsied, and she was started on a calcium balance. Stilboestrol 60 mg./day was given from 11 May 1966, and the progressive changes in the plasma calcium were noted from 15 May. Stilboestrol was discontinued two days later and 150 mg. of hydrocortisone a day was given intramuscularly. On the third day on this regimen with no immediate response, 500 ml. of 1% buffered sodium phosphate was given, and later that day (19 May) the patient died. Details of the calcium balance, electrolytes, and cardiogram are given in Figs. 1 and 2.

Post-mortem Findings.—The subject was a wasted female with a large carcinoma which involved most of the right breast and invaded the interstitial tissues and pleura. Metastases were present in the skin of the chest and abdomen, and in the ribs, vertebrae, and pelvis. The lymph nodes were not involved. Both lower limbs showed extensive subcutaneous haemorrhages. Only minor abnormalities were noted in the gross appearances of the other organs, including brown pigmentation of the myocardium, oedema and congestion of the lungs, fatty changes in the liver, and nodularity of the thyroid. Four parathyroids were dissected out and noted to be normal in size. Histology showed a poorly differentiated cellular carcinoma of the breast. Sections stained with von Kossa's stain

for calcium showed calcification of the cardiac muscle fibres, one lobe of the thyroid, renal tubules, parenchymal cells of the liver, and small arteries and arterioles. The renal involvement was unequal.

COMMENT

Previous to any therapy the patient was in approximate balance with a normal urinary calcium (230 mg./day), electrolytes, blood urea, and electrocardiogram. Within three days of her receiving oestrogens the plasma calcium had begun to rise, and three days later it had reached 14.7 mg./100 ml., with a urinary calcium of 650 mg./day. The mechanism of the hyper-

FIG. 1.—Serial estimations of the plasma concentrations of calcium, alkaline phosphatase, and phosphate. Calcium balance (incomplete terminally) is calculated by constructing the daily food intake downwards and adding the faecal and urinary excretion for each period upwards; negative balance is seen when the faecal and urinary excretion exceed the food intake and project above the zero line in the upper part of the diagram. P=Phosphate infusion.

FIG. 2.—Electrocardiographic record. Above, 28 April. Centre, 18 May. Below, 19 May.

calcaemia of malignant disease has often been reviewed (Watson, 1963); it can be due to simple osteolysis, the production of parathyroid-hormone-like peptides, or a nonspecific hypertrophy of the parathyroid glands (Kohout, 1966), and on occasion to the production of osteolytic steroids. In view of the extensive lytic deposits and the rising phosphate concentrations, the first cause seems most likely. Despite cessation of stilboestrol and the substitution of cortisone the plasma calcium continued to rise with the onset of uraemia and cardiographic changes (Fig. 1).

The usual recorded cardiographic features of hypercalcaemia are shortening of the Q-T interval, more rarely prolongation of P-R interval and inversion of the T wave, and on occasion bradycardia, A-V block, and bouts of fibrillation (Bradlow and Segal, 1956; Beck and Marriott, 1959; Bronsky, Dubin, Waldstein, and Kushner, 1961; Voss and Drake, 1967). In the three recordings the P-R interval remained short between the range 0.12 to 0.10 over the 12-mg. range from 10 to 22 mg./100 ml., the Q-T interval, corrected according to the formula $QT_c = QT \sqrt{R-R}$, ranged from 0.33 to 0.22, and the final cardiogram showed either considerable lengthening of this interval or that the T wave was buried in the S-T segment depression the next wave being a prominent U wave which was clearly apparent the day before. On the day of her death, with the infusion of phosphate, abrupt changes in the cardiogram took place with widespread S-T depression over the anterolateral segments (Fig. 2). In these circumstances, with the plasma calcium over 20 mg./100 ml. unresponsive to cortisone, it appears safer to rely on a profuse diuresis, possible dialysis, or chelating agents (Lischer, 1965) rather than on the administration of intravenous phosphate as recommended by Goldsmith and Ingbar (1966). This may lead to a $Ca \times PO_4$ ion product in excess of 2.4×10^{-6} moles/litre, which produces precipitation calculated from regression equations confirmed from the reduction of calcium both in normal and in hypercalcaemic subjects infused with phosphate (Hebert, Lemann, Petersen, and Lennon, 1966).

Injected calcium phosphate is preferentially taken up by cells lining small vessels (Gersh, 1937), and this may partly explain the calcification of the intima and media of the small arteries and arterioles of the myocardium.

We would like to thank Professor J. Anderson for his help and advice, and Mrs. P. Giles for technical assistance. Miss E. Knight was supported by the B.E.C.C.

Budd-Chiari Syndrome after Taking Oral Contraceptives

Brit. med. J., 1967, 4, 660

Budd (1846) reported a case of hepatic vein thrombosis caused by an abscess of the liver. Subsequently Chiari (1899) described three and reviewed 10 cases. Parker (1959) was able to find 149 cases described in the literature and contributed a further 18 cases. The syndrome seems to be more common in men than in women, and the average age at necropsy is 34 years. The possibility of an increased risk of thromboembolic disorders in patients taking oral contraceptives has been discussed lately. A number of case reports of thrombophlebitis and pulmonary embolism have been published, and the Medical Research Council (1967) has examined the question. Only one case of hepatic vein thrombosis in a young woman on oral contraceptive has been reported (Ecker *et al.*, 1966). The patient had been on norethisterone and mestranol (Norinyl) for 14 days when her symptoms started.

We have seen the Budd-Chiari syndrome in a previously healthy woman taking an oral contraceptive. Because of the possible causal relationship we consider the case worth reporting.

A 28-years-old housewife was admitted to hospital on 20 December 1966. Previous health had been excellent. For contraception she had periodically taken lynoestrenol plus mestranol (Lyndiol) during 12 to 18 months. The treatment was withdrawn on 12 December 1966 because of nausea. She had been taking no other drugs. During the last month before admission to hospital she had gradually increasing abdominal distension, epigastric pains, loss of appetite, and nausea. No jaundice or discoloration of faeces or urine were noted.

On admission her general condition was fairly good; no signs of anaemia or jaundice; no spider naevi or palmar erythema; abdomen grossly distended, with dilated abdominal veins; the liver was felt 8–10 cm. below the right rib margin, smooth, not tender; the spleen was enlarged; ascites present; on the side of the neck were several small lymph nodes.

Laboratory investigations showed: Haemoglobin, 14.7 g./100 ml. Erythrocyte sedimentation rate 7 mm. Leucocytes, 6,520/cu. mm., normal distribution. Alkaline phosphatase, 12.1 King-Armstrong units. S.G.O.T., 1.1. Thymol turbidity test, 0.07.

Epilepsy and Liver Dysfunction in Association with Hypernephroma

Brit. med. J., 1967, 4, 660–661

Mohamed (1965b) reported the case of a patient with a hypernephroma who died after a protracted illness associated with fever, anaemia, loss of weight, progressive hepatosplenomegaly, and, preterminally, episodes of grand mal epilepsy. At necropsy there was no evidence of metastatic spread, and Mohamed suggested that the epileptiform seizures and the liver-cell dysfunction would have resolved if the renal tumour had been resected during life. The present report would seem to support this prediction.

CASE REPORT

A 69-year-old man was admitted to hospital at the end of August 1965 because of drop attacks. He gave no history of loss of consciousness, vertigo, injury, or incontinence in association with these episodes. For three months before admission he had been unwell, anorexic, and losing weight. He also complained of a feeling of weakness in his legs, a tremor of his hands, frontal headaches, and nocturia.

Prothrombin, 71%. Bromsulphalein retention, 2%. Creatinine, 1.0 mg./100 ml. Benzidine reaction on faeces negative. Urine: no albumin, no sugar. Electrophoresis: albumin, 3.1%; gamma-globulin, 0.78%. Sigmoidoscopy, normal, no piles. Gynaecological examination normal.

X-ray examinations showed only raised diaphragm.

Needle liver biopsy (9 January 1967): liver tissue with acute congestion and fibrosis, presumably cirrhosis. Splenoportography (20 January) partly unsuccessful; rather large accumulation of contrast medium at the site of the spleen; faint filling of the normally formed vena lienalis. Microscopical evaluation of spleen puncture: relative lymphocytosis, otherwise no pathological changes.

The general condition of the patient deteriorated. Oedema of the legs developed and the ascites increased. Despite treatment she died on 14 March after repeated haemorrhages.

Necropsy.—Liver: 30 by 18 by 8.5 cm.; weight 3,330 g. Surface nodular consistency compact. Colour of surface varied from dark red to light bronze. In the right lobe were several 1- to 2-cm. yellow, soft necroses. Large confluent areas of the parenchyma showed haemorrhagic infarcts. Histological examination showed endophlebitis obliterans. A small hepatic vein showed thrombosis besides infarcts and some cirrhotic changes. Vena cava inferior: no thrombosis; all venae hepaticae were occluded at the junction with vena cava; in the liver a small thrombus in a larger hepatic vein.

Oesophagus: large contorted veins; 10 cm. from cardia a thrombosed vein in the wall.

Spleen: 16 by 10 by 6 cm.; weight 440 g.; congested.

Prospective studies running over a sufficiently long period are urgently needed to evaluate the risk of oral contraceptives.

We owe thanks to Dr. Ole Werdelin, University Clinic, Department of Pathology, for the necropsy report.

Parker, R. G. F. (1959). *Medicine (Baltimore)*, 38, 369.

On examination he was cachectic, pale, and apathetic. There was generalized muscle-wasting with fasciculation, and muscle power was diminished. Reflexes were present and equal, and the plantar responses were flexor. Some impairment of sensation in both feet and incoordination of movement of the left leg were found. Pulse rate was 48 and regular. Blood pressure was 140/80. There were no signs of cardiac failure. The liver edge extended three fingerbreadths below the costal margin and was firm and regular. Splenomegaly was not detected. Initially the patient was afebrile, but later he developed an intermittent pyrexia, his temperature being as high as 101° F. (38.3° C.) on several occasions.

Investigations.—Erythrocyte sedimentation rate was 134 mm. in first hour (Westergren). Haemoglobin was 7.7 g./100 ml., the red cells being hypochromic and microcytic. The reticulocytes were 1.4/100 red cells. The white cell count was 6,000/cu. mm. Examination of the sternal marrow showed evidence of active normoblastic erythropoiesis with occasional macronormoblasts. There was no excess of megakaryocytes or plasma cells. Iron storage appeared to be abundant. Plasma urea, electrolytes, bilirubin, aspartate aminotransferase, and alanine aminotransferase were all normal. The plasma alkaline phosphatase was raised to 33 K.A. units/100 ml., and the bromsulphalein test was abnormal, there being 35% retention at 25 minutes and 28% at 45 minutes. The prothrombin time was 17 seconds (control 15 seconds). The plasma albumin/globulin ratio was reversed. Electrophoresis showed an increase in all globulin fractions, especially alpha-2. Urine analysis was negative.

Two weeks after admission the patient had a grand mal convulsion. This attack appeared to be different from the episodes he had had before admission. C.S.F. examination was negative. E.E.G. showed considerable generalized abnormality, the background activity being dominant from between 6 and 7 cycles per second.

By about the third week of admission the liver appeared to have diminished in size, and it was then possible to detect a separate ballotable mass in the left hypochondrium. A few pus cells and red cells were noted in the urine, and these findings led on to intravenous pyelography. This revealed some displacement and deformity of the calices of the left kidney, and possibly a mass arising from the midportion of that kidney.

A left nephrectomy was performed on 30 September 1965 (Mr. W. Campbell). The kidney was seen to be completely replaced by tumour tissue, and there was extension into the renal vein. Histology confirmed that the tumour was a hypernephroma. There was no evidence of hepatic secondaries, either grossly or on microscopy of a biopsy specimen.

The patient made a good recovery after the operation. He gained weight rapidly, the hepatomegaly disappeared, and the liver-function

tests reverted to normal (see Chart). Two months after the operation an E.E.G. was normal. Ten months after the nephrectomy the patient was still very well. Four months later he died quite suddenly. Necropsy was limited to determining the cause of death. This was due to coronary thrombosis. There was no macroscopic evidence of metastasis in the liver or other organs, but the brain was not examined.

COMMENT

Hepatomegaly and non-metastatic liver-cell dysfunction, with return to normal on removing the renal lesion, is now well documented (Stauffer, 1961; Greenberg *et al.*, 1964; Mohamed 1965a), our case being the fifteenth to be reported. It is important that this syndrome is recognized, for there is a tendency to refuse operation to patients with hepatomegaly and a raised alkaline phosphatase on the assumption that the patient already has liver metastasis and the condition is then irremediable (Sherlock, 1963). Patients with hypernephroma may have extreme cachexia and impairment of cell function without metastasis (Creevy, 1935; Mohamed, 1965b).

The reversal of the signs and symptoms after nephrectomy in the above case could also have been related to spontaneous regression of carcinoma at other sites, and this possibility cannot be definitely excluded, particularly in relation to the brain.

It is a pleasure to acknowledge the assistance given by Dr. John Laidlaw, Chalfont Colony, Bucks, with the interpretation of the E.E.G.s. We are grateful to Mr. W. Campbell, who performed the nephrectomy and liver biopsy, and to Dr. D. G. Rushton, who carried out the necropsy.

Changes in E.S.R., haemoglobin, platelets, plasma alkaline phosphatase, B.S.P. excretion, plasma proteins, and body weight before and after nephrectomy have been plotted. The vertical dotted line indicates the day of operation. The improvement in haemoglobin level before operation was due to blood transfusion.

Relapsing Polychondritis

Brit. med. J., 1967, 4, 661-662

Relapsing polychondritis is a disease of which the main features are episodic inflammation, followed by dissolution, of cartilage throughout the body. In addition, there is often inflammation of the iris and sclera. It should be noted that the disease has been described under various titles. These include "chondromalacia," "chronic atrophic perichondritis," "diffuse perichondritis," "polychondropathia," and "relapsing polychondritis." The latter designation has been favoured by most recent authors.

The first case was probably described by Jaksch-Wartenhorst (1923). Since then nearly 50 cases have been reported, but only two of them are in British literature (Rhys Davies and Kelsall, 1961; Thould, Stansfeld, and Wykeham Balme, 1965).

CASE REPORT

A housewife had been in previously good health apart from a cough which she said she had had all her life. Her family history was non-contributory. In 1956, when aged 41, her cough became worse, and some wheezing and mucopurulent sputum developed. The symptoms were all worse in the winter.

In 1961 painful swelling of the ankles and knees developed. The erythrocyte sedimentation rate (E.S.R.) at this time was 60 mm. in one hour (Westergren). The Rose-Waaler test was said to be positive but the titre was not known. She was given a short course of corticosteroids and her joint symptoms subsided.

In January 1962 she became short of breath and developed stridor. Her voice became hoarse. She developed swelling of both pinnae and her ears became "like cauliflowers." At the same time she had an episode of right-sided iritis. Effusions into both knee joints were noted. At this point some falling in of her nose was noticed. Laryngoscopy showed "swelling and spasm of the whole laryngeal inlet." A biopsy of the tracheal wall showed extensive chronic granulation tissue deep in the wall with dense hyaline fibrosis

of the lamina propria. The Rose-Waaler and Kveim tests were negative. Renal function tests were normal. Tracheostomy was performed because of the respiratory obstruction. A small dose of radiotherapy was given to the larynx.

She had a persistent cough with much sputum, which required to be aspirated many times daily. Her ears gradually returned to their normal size. Apart from several further episodes of iritis her condition remained otherwise virtually unchanged until February 1965, when she experienced some difficulty with inserting the tracheostomy tube. Bronchoscopy showed narrowing of both the trachea and the origins of the main bronchi (see Table) and the mucosa was granular and irregular. Biopsy of the tracheal mucosa showed squamous metaplasia with marked fibrosis. At this point prednisolone 20 mg. daily was given.

Corrected Measurements of Tracheal and Bronchial Diameters

	Normal Control	Patient
Trachea 2 cm. above carina	2 cm.	0.74 cm.
Right main bronchus 1 cm. below carina	1.2 "	0.67 "
Left " " 1 " " " "	1.0 "	0.67 "

She was admitted to the Churchill Hospital in April 1965, under the care of Dr. J. M. K. Spalding, because of difficulty with her tracheostomy. The depression of the middle of her nose was pronounced (Fig. 1) and the nasal cartilages were very soft. The right ear was somewhat soft and flabby. Her hearing was normal to ordinary ward testing. There was no objective evidence of past iritis. The tracheostomy tube was in situ and appeared to be satisfactory. There was some tenderness over the sternomanubrial joint. The other joints were objectively normal.

Investigations showed a mild hypochromic anaemia. The E.S.R. was 11 mm. in one hour (Westergren). The Wassermann reaction and Rose-Waaler test were negative. L.E. cells were not seen. No antinuclear factor was demonstrable. The total serum proteins

FIG. 1.—Photograph showing depression of middle of nose.

FIG. 2.—Tracing of inclined frontal plane tomograph taken through the plane of trachea and main bronchi.

were 6.6 g./100 ml. Serum electrophoresis showed a slight increase in the alpha-2-globulin and gammaglobulin. A midstream specimen of urine was normal. There was no excess of mucopolysaccharides in the urine. The blood urea was 26 mg./100 ml. The maximum urinary specific gravity was 1020. The creatinine clearance test was 82 ml./min.

Plain x-ray films of the chest were normal, but tomograms revealed gross narrowing of the trachea and main bronchi (Fig. 2). Lung-function tests were performed by Dr. R. Marshall, who reported as follows: "In this patient there is considerable increase in airway resistance. At normal flow rates (up to 0.5 l./min.) the resistance during inspiration is approximately the same as during expiration. At higher flow rates the resistance increases on expiration and the maximum possible expiratory flow is about 0.7 l./sec." There was sclerosis of the sternomanubrial junction. X-ray examination of the cervical and lumbar spines showed only non-specific degenerative changes. X-ray films of the hands and knees were within normal limits.

Since April the patient had remained reasonably well and was taking prednisolone 5 mg. t.d.s. In October 1965 she had a mild relapse involving painful swelling of both ears. This subsided without a further increase in her steroid therapy.

DISCUSSION

This patient shows the classical features of relapsing poly-chondritis. Most authors have reported single cases. Kaye and Sones (1964) reviewed 14 personal cases, together with 27 cases collected from the literature.

The disease is characterized by episodes of activity in which cartilage in various sites becomes inflamed. The episodes are often accompanied by low-grade fever and malaise. Recurrent episodes of activity ultimately produce softening of the affected cartilage. The pinnae become soft and flabby and the nose assumes a "saddle-nose" deformity. Involvement of the middle and inner ear may lead to deafness.

The cartilages of the respiratory tract are often involved, and ultimately narrowing of the trachea and bronchi may occur. This involvement of the respiratory tract is the usual cause of death. Cartilaginous joints such as the symphysis pubis and the manubrium sterni are sometimes affected. Synovial joints are affected in some cases, and occasionally a polyarthritis resembling rheumatoid arthritis may occur (Thould *et al.*, 1965). Three of the cases reported by Kaye and Sones (1964) fulfilled the criteria for definite rheumatoid arthritis laid down by the American Rheumatism Association (1959). The eye is involved in about one-third of reported cases. Scleritis, conjunctivitis, and iritis may all occur.

The E.S.R. is often raised during an exacerbation. Tests for rheumatoid factor are usually negative. During an exacerbation there may be an increase in urinary mucopolysaccharide excretion. The cause of the disease is unknown.

Steroids appear to suppress the inflammatory reaction, and if the respiratory tract is involved, long-term steroid therapy is probably indicated. Treatment is otherwise symptomatic.

My thanks are due to Dr. J. M. K. Spalding for permission to publish this case; and to Dr. D. Davies, Physician-Superintendent, Ransom Hospital, Rainworth, near Mansfield, Notts, for referring the patient and for the early investigations. I also wish to thank Dr. R. Marshall for undertaking the lung-function studies.

RICHARD L. HEWER, M.B., B.S., M.R.C.P.,
Senior Registrar in Neurology to the United Oxford
Hospitals.

Current Practice

DISEASE OF THE DIGESTIVE SYSTEM

Dysphagia

CLIFFORD F. HAWKINS,* M.D., F.R.C.P.

Dysphagia is a precise symptom that must never be ignored. The diagnostic net must be cast widely, but three likely causes are carcinoma, achalasia, and hiatus hernia—the most important to exclude being carcinoma. The oesophagus is of interest to the cardiologist, as pain arising from it can mimic myocardial ischaemia, and some patients with oesophageal obstruction may first be seen by the chest physician because of aspiration pneumonia.

Accurate diagnosis is possible in most cases if the taking of a careful history is combined with thorough radiographic examination. This may include giving the patient a solid bolus of barium and watching him swallow when lying horizontally or head-down. It is often helpful to see the patient eat or drink. In achalasia trick movements such as attempts to breathe out forcibly through a closed glottis may help to force food

scopy and biopsy are conclusive in most cases. Oesophageal perfusion with N/10 hydrochloric acid can be used as a provocative test to distinguish oesophageal from cardiac pain.¹

Carcinoma of Oesophagus

This is one of the most deadly cancers, the reason being not the type of neoplastic cell—most are squamous—but the surrounding anatomy of the oesophagus. As soon as the growth trespasses beyond its walls vital structures like the lung, the bronchi, or the aorta are invaded, either directly or by lymphatic spread. Hope of cure lies in early diagnosis.

Carcinoma of the oesophagus occurs particularly in men over the age of 65, though it may be a complication of chronic iron deficiency anaemia in women. Heavy smokers are slightly more prone to the disease, presumably because of the action of a swallowed carcinogen. Its incidence is high in certain races, notably among male Bantu—perhaps as a result of their drinking "cidivici," a native beer brewed illicitly—and among female Eskimos, probably because they chew edges of sealskins when making mukluks.² Chronic oesophagitis and oesophageal obstruction may predispose to neoplastic change, which would explain the slightly increased incidence of carcinoma in patients with long-standing hiatus hernia and achalasia.

The dysphagia, which is sometimes preceded by vague substernal sensations, is progressive and contrasts with the intermittent dysphagia of some benign conditions. It first affects solids, then liquids. A barium swallow may not show an early growth, so oesophagoscopy must be performed whenever the condition is suspected, and biopsies should be taken

FIG. 1.—Pharyngeal pouch.

through the cardia. High oesophageal obstruction may cause the patient to eat with rabbit-like movements of the jaw for fear of letting food leave the mouth. One patient complained of a lump in the throat when drinking beer quickly, and he needed little encouragement to demonstrate this to us; later a barium swallow showed the pharyngeal pouch (Fig. 1). Special investigations such as cineradiography and manometry may be used to study disorders of oesophageal motility such as achalasia, diffuse spasm, and scleroderma. Some workers have found exfoliative cytology helpful in diagnosing carcinoma in conditions like achalasia, where the changes already present make detection of malignancy difficult. However, oesophago-

FIG. 2.—Adenocarcinoma of fundus of stomach invading lower oesophagus.

* Consultant Physician to the United Birmingham Hospitals and Lecturer in Clinical Medicine to the University of Birmingham.

from suspicious areas. Though the usual type of carcinoma is squamous, adenocarcinoma occurs in the lower oesophagus. This may arise in the cardia or fundus of the stomach and invade the oesophagus later (Fig. 2). Then the patient tells the story of dyspeptic symptoms for several months followed by dysphagia—an ominous sequence of events.

The radiological appearance of carcinoma of the oesophagus is frequently characteristic. There is a short narrowed segment and its irregular outline usually, though not invariably, distinguishes it from achalasia (Fig. 3). Occasionally there is a longer area of minimal narrowing, which is easily missed; this is caused by an extensive flat ulcerating carcinoma, in which the mucosal pattern is lost.

FIG. 3.—Carcinoma of oesophagus.

Radiotherapy may be the best treatment for growths in the upper third of the oesophagus because of their inaccessibility and the poor surgical results, but surgical treatment should always be considered for lesions elsewhere. If it is not possible to remove the growth some treatment is usually necessary to prevent the death of the patient from starvation. Gastrostomy has been abandoned, for it merely prolongs a miserable existence and for a short time only; the patient's inability to swallow saliva is pathetic. Palliative operations may be of great relief when resection is impossible. A bypass operation, such as oesophago-jejunostomy, may be feasible, though procedures of this type have a high mortality. It is often preferable to force some type of tube through the growth, either via an oesophagoscope or directly through a slit in the oesophagus above the lesion. A wide range of indwelling tubes has been devised for this purpose.

Achalasia

Achalasia of the cardia (formerly called cardiospasm) is a benign treatable condition caused by failure of the cardia to relax before the oncoming bolus of food, because of degeneration in Auerbach's plexus. Most patients are between 20 and 40 years old, though no age is exempt. The patient feels that food sticks behind the lower sternum; solids and liquids are equally affected and the dysphagia is usually painless. The patient has to eat slowly, and regurgitation of food may embarrass him and sometimes lead to lung complications.

Achalasia is a neuromuscular disorder of the whole oesophagus. Early diagnosis before obstruction has developed may be difficult. A patient occasionally complains of substernal pain from oesophageal spasm or discomfort, which may be attributed to "indigestion"; regurgitation may be mistaken for vomiting and a peptic ulcer may be diagnosed, the dysphagia being overlooked. In the early stages the barium swallow may be normal except for signs of disordered motility or persistent failure of the cardia to open; this is best shown by giving the patient a small breadcrumb soaked in barium to swallow, when it will lodge at the cardia. The methacholine test is useful: 5 to 10 mg. of methacholine chloride is injected subcutaneously, when in achalasia violent painful contraction of the lower half of the oesophagus will result which may obliterate the lumen when seen by x-ray. The test is positive in achalasia except in advanced stages, and it is usually negative in carcinoma, scleroderma, and diffuse spasm.

Barium swallow typically shows a cucumber-shaped oesophagus with a tapering lower end (Fig. 4). There is complete loss of the peristaltic wave, this being replaced by segmental and tertiary contractions. The cardia is eventually forced open by the column of food when it is about 20 cm. high. This column also acts as a trap, so that no gastric air bubble is visible (Fig. 4). Sometimes a mega-oesophagus flops into the right chest, when it is described as a sigmoid oesophagus; because of the sigmoid shape the direct effect of gravity on the sphincter is lost. Patients with untreated achalasia lose weight, though they seldom die from starvation.

FIG. 4.—Achalasia of the cardia.

Oesophagoscopy is required, especially in doubtful cases, as carcinoma of the oesophagus can mimic achalasia (Fig. 3) and also complicate it. In addition to the methacholine test given with the barium swallow other drug tests may help in the diagnosis; inhalation of octyl nitrite relaxes smooth muscle transiently, and the oesophagus will empty in achalasia, though not in other conditions. To avoid unpleasant side-effects of this drug hyoscine-N-butylbromide (Buscopan), which has a similar effect, is preferable, and 20 mg. should be given subcutaneously or intravenously. Unfortunately these drugs are of little use in treatment. Heller's operation of myotomy should be advised as a curative procedure; it diminishes the hydrostatic pressure necessary to force food through the stomach. Alternatively, dilatation by the Negus hydrostatic bag can be

used. Whatever the treatment, the motility defect of the oesophagus remains and no patient with achalasia can swallow upside down.

Chagas disease (South American trypanosomiasis)—a parasitic disease especially prevalent in Brazil—causes destruction of ganglion cells in the bowel wall, leading both to achalasia and to megacolon.

Other Disorders of Motility

Sometimes the cricopharyngeal muscle fails to relax and leads to a feeling of food sticking in the throat, a symptom easily regarded as hysterical when the patient is highly strung. This incoordination of deglutition occurs with a pharyngeal pouch and may be the cause rather than the result of the pouch.³

Diffuse oesophageal spasm causes retrosternal pain and dysphagia and sometimes progresses to achalasia. Motility studies are usually required to show the motor dysfunction, though sometimes it may be seen during radiographic examination. As barium reaches the level of the aortic arch the lower half of the oesophagus suddenly becomes distorted and the outline is puckered into a series of pockets, giving it a beaded or corkscrew appearance (Fig. 5); these pockets are zones of lesser pressure into which barium is forced. A thickened oesophageal wall may develop and this hypertrophy may account for the high pressures which have been recorded. The diagnosis should be suspected in patients who have episodes of substernal pain unrelated to exercise and without disease of the upper alimentary tract, gall bladder, or pancreas. The pain may resemble angina, and caution is needed in making the diagnosis of oesophageal spasm, for these motility changes can be an incidental symptomless finding, especially in the elderly.⁴ Nitroglycerin may relieve this pain, for it also relaxes smooth muscle; relief has been given in severe cases by a long myotomy incision in the lower oesophagus.⁵ The case for regarding this condition as separate from achalasia is based on the motility pattern of the oesophagus and the normally functioning intrinsic sphincter, though the dividing line is by no means always clear.

FIG. 5.—Oesophageal spasm producing the appearance of corkscrew oesophagus and pseudo-diverticulosis.

Hiatus Hernia

Hiatus hernia, which was described in detail earlier in this series of articles,⁶ is the commonest cause of oesophagitis. The oesophageal mucosa has no protection against peptic digestion from gastric juice. Reflux of gastric contents occurs especially in the sliding type of hernia, where an incompetent cardia lies in the chest, whereas the anatomy of the cardia may be retained in the paraoesophageal type and prevent reflux. The special symptom of reflux is postural heartburn. Patients may find bending down so unpleasant that they have special long-handled tools made for housework or gardening, and their night's rest may be spoiled. Sometimes they also complain of the mouth unexpectedly filling with partially digested food. This must not be confused with vomiting, which is usually preceded by nausea.

Stricture may be the sequel of long-standing oesophagitis. Heartburn and regurgitation may then cease as the stricture prevents reflux of gastric contents. These patients present a challenge to the surgeon. Some will back optimism and try the effect of repair of the hernia alone, as sometimes the oedema and inflammation around the stricture will subside; others attempt a more radical approach, using an isolated jejunal segment or gastric tissue to form a connecting tube between the lower end of the shortened oesophagus and the stomach itself.

Fortunately, a fibrous stricture occurs in only a few patients with hiatus hernia. Dysphagia in others is due to oesophageal spasm, and responds to treatment of the oesophagitis. The difficulty in swallowing then becomes intermittent and may be described as a feeling of a lump in the chest or temporary sticking of food.

Though hiatus hernia is the commonest cause of benign oesophageal stricture, all patients, except those with an obvious cause such as trauma or damage from corrosive agents, should undergo oesophagoscopy and biopsy to exclude carcinoma.

Other Causes of Oesophagitis

Bacterial or tuberculous infections of the mouth and pharynx may spread downwards and attack the oesophagus, when difficulty in swallowing will be caused by pain. Physical agents such as hot liquids or irradiation may cause similar symptoms. The heartburn, which may be the penalty for an alcoholic bout, is probably due to chemical oesophagitis. Additives to food or drink may be injurious. This was illustrated by the epidemic of cardiac and gastrointestinal disease among beer drinkers in Quebec during 1965–6. Necropsy showed that some had oesophagitis and severe gastritis with ulceration.⁷ The illness was caused by cobalt, which had been added to draught beer to improve the "head," as this was being increasingly subdued by detergents on poorly rinsed glasses. A iatrogenic cause of oesophagitis which may lead to heartburn and stricture is the prolonged use of the indwelling nasogastric tube, for it keeps the cardia open and allows acid reflux when the patient is nursed supine.⁸

Chronic oesophagitis also follows reflux of bile and pancreatic juice, which may be a sequel to gastric operations. The early morning "vomit" of the chronic alcoholic is usually oesophageal mucus which is secreted overnight. Chronic inflammation may be due to stasis from oesophageal obstruction. Antibiotics can cause dysphagia, especially in those weakened by prolonged illness and receiving corticosteroids. This is due to oesophageal candidiasis (thrush), which is usually present in the mouth or pharynx as well. Barium swallow may show an irregular filling defect in the oesophagus, which resembles the appearance of varices. The antibiotic should be stopped if possible and an antifungal agent such as nystatin given instead.

The ideal treatment of oesophagitis is removal of the cause; this may entail surgical repair of a hiatus hernia. Otherwise, simple mechanical measures intended to discourage reflux may

be advised: raising the head of the bed, avoiding constricting garments, and reduction of weight. Patients should be told to chew their food properly and their dentition should be adequate; roughage should be avoided during bouts of dyspepsia. Antacids pass rapidly through the oesophagus and have no permanent effect, though they afford temporary relief from the heartburn, as do solutions containing a surface anaesthetic, such as Mucaine. The constant sucking of antacid tablets (such as Nulacin or Prodexin) has been shown to keep the gastric acidity near pH 3.0,⁹ and some have advised a constant antacid drip through a thin polyethylene nasal tube lying in the mid-oesophagus; this, which is particularly useful at night, allows meals to be taken as usual during the day. Anticholinergic drugs are useless, for they are disappointing in their effect on gastric acidity and may cause more reflux by relaxing the cardiac sphincter.¹⁰

Other Forms of Obstructive Dysphagia

Foreign bodies must always be considered as a cause of dysphagia. There is usually a history of choking during a meal, though this may not be obtained in small children and in psychotic patients. For example, one patient of mine, a middle-aged woman with neurotic symptoms, complained to her general practitioner of dysphagia. He diagnosed globus hystericus and told her that it was "the change." He was in a way correct, for she had swallowed 2s. 4d., the change which she had received when shopping. Removal of a foreign body is an urgent matter, for it may lead to ulceration and cause fatal mediastinitis.

Dysphagia from pressure on the oesophagus in the neck or thorax may be caused by conditions such as enlarged lymph nodes, neoplasms of the lung or mediastinum, aneurysm, or a large retrosternal goitre.

Syndromes have a status denied ordinary symptoms or diseases, although their statistical basis is sometimes doubtful.¹¹ This may be the case in the syndrome of anaemia, glossitis, and dysphagia. Originally christened the Plummer-Vinson syndrome (although Vinson regarded it as hysterical), it should

FIG. 6.—Postcricoid pseudo-web associated with iron-deficient anaemia (by courtesy of Dr. J. S. Logan).

be named after Paterson and Kelly, for these workers noted it earlier and wrote a perfect description of the postcricoid web. Now, an epidemiological study has shown no evidence of a significantly increased prevalence of anaemia or latent iron deficiency in women with postcricoid dysphagia or with webs.¹² However, some women with long-standing iron-deficient anaemia do suffer from dysphagia, glossitis, and an atrophic mucous membrane of the pharynx and cricopharyngeal area. The accompanying loss of sensibility impairs the afferent side of the swallowing reflex, and if the anaemia is untreated a benign thin crescentic pseudo-web of the mucosa (Fig. 6) or carcinoma develops at this site. Webs, congenital, traumatic, or due to pemphigus, may occur elsewhere in the oesophagus and not give rise to symptoms until lumps of meat are eaten hastily. Webs are easily missed at barium swallow when situated just above the cardia unless a large bolus of barium is used. Patients can usually be encouraged to live with their difficulty, and surgery is rarely needed. The lower oesophageal ring (Schatzki's ring), which is often associated with hiatus hernia, is a similar harmless lesion and should not be confused with fibrous stricture.

Dysphagia lusoria (Fig. 7) is due to oesophageal compression by the arteria lusoria, an anomalous form of the right subclavian artery. Other congenital abnormalities may be present

FIG. 7.—Dysphagia lusoria.

as well. Symptoms may appear in infancy or later in life, then perhaps being precipitated by arteriosclerotic changes in the artery. An explanation to the patient with reassurance is usually all that is needed.

Oesophageal Lesions in Systemic Disease

The oesophagus bears the main brunt when the alimentary tract is involved in scleroderma. It is dilated and transit through it so slow that barium is retained for half an hour or longer. A test for the detection of early cases is for the doctor to watch the patient swallowing barium against gravity, as when inclined head-downwards; barium hovers at the level of the tracheal bifurcation and enters the stomach only when the patient stands. Other connective tissue disorders also affect the alimentary tract. Dermatomyositis may lead to dysphagia

because of weak pharyngeal muscles or a motility defect in the oesophagus. The diagnosis is suggested by the dermatitis which is usually present and can be confirmed by muscle biopsy and enzyme tests. Some cases are due to malignant disease, either in the alimentary tract or elsewhere, and a search must always be made for this.

Neurological disorders may impair swallowing. Because of his mental state this may escape the notice of the patient as well as the medical staff, and he may die from aspiration pneumonia. Every patient with a stroke must be examined with this possibility in mind. The gagging reflex should be sought, and the patient should then be asked to swallow a mouthful of water. Dysphagia may also occur in patients with bulbar paralysis, myasthenia gravis, polyneuritis, and similar conditions.

Globus hystericus, though relatively common, has been left until last, and indeed should not be diagnosed unless serious disease has been excluded. An intelligent woman who can describe her symptoms clearly explains that she has a feeling of a lump in the throat but does not have difficulty in swallowing. Others are less precise. It is salutary to remember that probably every organic cause of dysphagia described here has at some time been mistaken as nervous, the patient then being labelled—and libelled—as hysterical.¹³

ANY QUESTIONS?

We publish below a selection of questions and answers of general interest.

Stability of Ergometrine and Adrenaline

Q.—Is the yellow discoloration of ergometrine for injection after storage of any significance? How long can ergometrine injection and adrenaline for injection be kept before use?

A.—The stability of ergometrine preparations has been investigated by Foster and Stewart.¹ They showed that the official B.P. formula has satisfactory keeping properties. Samples stored at room temperature retained 90% of their activity after 33 months. In the discussion on this paper Eastland² reported that some ampoules with colours from a dark straw to blackish-brown had retained 86% of their activity. It seems likely that injections that are not more than a yellow colour will not have lost much activity.

The *United States Pharmacopoeia* states that ergometrine injection should be used within two years of preparation. A report of the Danish Academy of Technical Sciences,³ however, suggests an expiry date of three months. This is obviously a very conservative estimate of the shelf-life of the product, and the U.S.P. figure is probably satisfactory.

The stability of injections of adrenaline has been studied by West^{4,5} and by Foster, McDougall, and Thorp.⁶ They showed that solutions stored in ampoules are very stable, some samples retaining full activity after six years or more. West and Whitter⁷ showed that injections of adrenaline stored in rubber-capped vials are much less stable. The Danish report gives an expiry date of one year

for injection of adrenaline. This is probably advisable for samples in multidose containers, but those in ampoules could probably be kept for considerably longer periods.

Erythromycin

Q.—What are the merits of the various esters of erythromycin that are available?

A.—The only commercially available ester is erythromycin estolate (Ilosone), which is the lauryl sulphate of the propionyl ester. Its merit is better absorption, the concentrations attained in the blood being considerably higher than those produced by the same dose of erythromycin base. It has also a drawback in that full doses given for more than a week sometimes have a reversible hepatotoxic effect. An ester of a related antibiotic, triacetyleandomycin, can also have the same effect. It has not been seen after administration of non-esterified forms of either antibiotic.

Erythromycin stearate, another form in which erythromycin is marketed, is not an

ester. Its advantage is resistance to gastric acid, whereas the base, which is acid-labile, has to be administered in enteric-coated tablets.

Children with Dyslexia

Q.—What is the treatment and what is the prognosis in a boy aged 7 suffering from dyslexia? Are there any special schools for children with this disability?

A.—Dyslexia means defective reading, and in a child aged 7 it might be due to a variety of factors, such as mental subnormality; sensory defects of vision or hearing; deficient or improper teaching by reason of insufficient or poor schooling, or frequent changes of school; poor motivation to learn, despite adequate opportunity; or it may be secondary to a primary emotional problem. In a smaller group it might be due to late development with slow learning, usually self-correcting, but this may progress to outright retardation in reading.

For these reasons, and because of the variety of teaching methods employed in different schools, many authorities are reluctant to talk of dyslexia in a child aged 7. In the smallest group, more often older children, the diagnosis of "specific developmental dyslexia" may be made in those who are unable to read with normal facility despite normal intelligence, intact senses, proper instruction, and normal motivation. These children are often competent in other subjects not dependent on reading skill.

Treatment and prognosis in the three groups differ according to cause. In the first two groups assessment via the school psycho-

logy service will define the majority of the causes and special medical examination the others, so that appropriate corrective and remedial measures can be taken. In the third group special techniques of remedial teaching are required over a long period of time and response may still be poor.

There are no schools at present dealing specifically with children with reading retardation, though different types of special education can be recommended, depending on the particular case. The Invalid Children's Aid Association's Word Blind Centre for Dyslexic Children, Coram's Field, 93, Guilford Street, London W.C.1, assesses and treats a variety of cases.

Vitamin B₁₂ Absorption from Ileum

Q.—When it is necessary, in the presence of extensive adhesions, to perform an ileo-transverse colostomy for a faecal fistula of the terminal ileum can the megaloblastic anaemia of a malabsorption syndrome be prevented by prolonged parenteral administration of vitamin B₁₂? What length of terminal ileum absorbs vitamin B₁₂? What effects of malabsorption other than megaloblastic anaemia are produced by an ileo-transverse colostomy, and can they be prevented by subsequent medical treatment?

A.—In this situation, where the underlying process is almost certainly Crohn's disease, regular injections of vitamin B₁₂ will prevent or correct the megaloblastic anaemia. Vitamin B₁₂ is mainly absorbed in the terminal few feet of ileum, but the whole ileum has this ability to some extent. It is sometimes difficult to predict how disease will affect vitamin B₁₂ absorption, and a Schilling test is often valuable to assess this function.

An ileo-transverse colostomy is rarely accompanied by other evidence of malabsorption, but when there is extensive Crohn's disease, blind loops, or internal fistulae malabsorption may occur with steatorrhoea, hypocalcaemia, and hypoproteinaemia. When there is no other disease of the bowel and the patient has steatorrhoea a low fat diet with replacement of any deficiencies is the treatment of choice.

Desensitization to Wasp Stings

Q.—Is desensitization against wasp stings effective, and what is the best preparation to use? What emergency treatment should be given for an acute reaction to a wasp sting?

A.—Desensitization to the stings of insects, including bees and wasps, can be an effective form of treatment. Complete desensitization is rarely achieved and the effect is likely to be only temporary. Annual desensitization is therefore advisable, especially in those whose occupation brings them into contact with bees or wasps.¹

Extracts of whole bee or wasp are used, and in this country aqueous extracts are available. They may be given subcutaneously

or intradermally.² In America oily emulsions containing the active agent are sometimes employed and hyposensitization may be achieved with a few injections only.³ Such preparations are not available at present in this country.

The immediate treatment for a reaction to a wasp sting is adrenaline hydrochloride (1:1,000) 0.5–1 ml. subcutaneously. This may be life-saving. The sensitive patient may be provided with a syringe and an ampoule of adrenaline tartrate. Speed in treatment is essential, since collapse and death may occur within one minute. The injection may need to be repeated if symptoms recur after an interval. When the sting is on an extremity a tourniquet should be applied until the adrenaline has had time to act, and at the same time 0.5 ml. adrenaline hydrochloride may be injected into the site of the sting to slow up absorption. Phen-ergan (promethazine hydrochloride) may also be given intravenously, but it is less effective than adrenaline.

There is no place for corticosteroids in the first instance, but intravenous hydrocortisone may prevent recurrent attacks of urticaria and asthma when the effect of adrenaline and antihistamine has worn off.

Ruptured Cruciate Ligaments

Q.—Is it possible to repair the cruciate ligaments of the knee joint eight months after rupture? Is there any other treatment of value?

A.—Late repair of the cruciate ligaments has been attempted by numerous operations, usually substituting strips of fascia or the meniscus for this important stabilizing ligament of the knee. The wide variety of technical procedures developed is the best indication that no one of them is satisfactory.

Though there would be much difference of opinion among orthopaedic surgeons, I have not seen results from any of these procedures that justify operative repair. The maintenance of an excellent quadriceps is the best aid to a patient that can be devised. Torn cruciate ligaments, usually the anterior, are very common, and relatively few people have disability except when attempting the most strenuous sports.

Cocaine in Asthma

Q.—Instillation of 1 ml. of 10% cocaine through the cricothyroid membrane into the lumen of the trachea is said¹ to terminate an asthmatic attack even in severe status asthmaticus. Does this mean that the bronchospasm of asthma is caused by the action of irritants on the tracheal or bronchial mucosa?

A.—The injection of 10% cocaine through the cricothyroid membrane in status asthmaticus is rarely employed and not devoid of risk. The way in which relief is obtained from it is uncertain, but it is probably from a vasoconstrictor effect as much as from the

action on nerve endings. It also potentiates the effect of sympathetically innervated organs to sympathomimetic drugs. There is evidence that it has an effect antagonistic to serotonin in animals.² Severe toxic reactions may occur after as little as 20 mg.,³ and allergic responses with sudden death are also recorded.⁴ Finally, when repeated there is always a possibility of addiction.

Oral Candidiasis

Q.—What further treatment is there for a chronic monilial infection of the mouth which has failed to respond to nystatin, gentian violet, and dequalinium?

A.—Chronic monilial infection is usually extremely resistant to conventional treatment, but iodides, amphotericin B, and desensitization are other methods that have been recommended. Presumably underlying causes, such as poorly fitting dentures, diabetes, hypoparathyroidism, and chronic debilitating diseases, have been excluded.

Non-rubber Gloves

Q.—Is there any sort of rubber glove which may be worn by a person who is allergic to rubber, or is there any other way of overcoming the problem?

A.—In cases of allergy to rubber the allergen is never the latex itself but always a chemical additive. Several types of non-rubber gloves or gloves which do not contain these additives are available. They may be made of cellophane, polythene, or polyvinyl-chloride. A French company makes special gloves based on yet another type of plastic.

Notes and Comments

Muscular Spasms in Paraplegia.—Dr. T. K. DAVIDSON (Physical Medicine Department, General Hospital, Northampton) writes: With reference to this question ("Any Questions?" 28 October, p. 221), and particularly with reference to what I take to be flexor spasms, I have for some time now, on a wide variety of spastic muscles, used 5 ml. of 1% procaine and 5 ml. of 40% sterile ethylalcohol. This is injected in and around the motor point of the muscle in spasm.

In the case of flexor spasms in the hip injection into rectus femoris and/or sartorius will relieve the spasm to a considerable extent. If the main trouble is spasm of the hamstrings it may well be that semitendinosus is the main cause of it, and injection of this alone may give considerable relief. If it does not it may be necessary to inject both heads of biceps and semimembranosus—and even gracilis. This procedure can be repeated at 12- to 18-monthly intervals. It is said to act by knocking out the gamma fibres from the stretch receptors. Whatever the physiology, it is certainly a very useful and worth-while procedure.

Book Reviews

Mental Health Services in Many Countries

New Aspects of the Mental Health Services. Edited by Hugh Freeman and James Farndale. (Pp. 776 + xvi. £9 9s.) Oxford: Pergamon, 1967.

Observers of the new colossus of the medical publishing world, the Pergamon Press, have learned to nerve themselves against the shock of high prices, but this volume of collected papers, at nine guineas, is still astonishingly expensive. Relatively few clinicians, and fewer academics or research workers will be likely to buy a personal copy; but if it is available to them through a hospital or departmental library, will they want to consult it? The answer to this question is an unequivocal yes.

There are many papers here which are of the greatest interest to workers in all ranks of all the disciplines which contribute to the functioning of our mental health services. It should be noted, however, that the editors have cast their net even wider than the title suggests. More than 25% of the book is taken up by a section entitled "The International Scene." Some of the papers in this section, describing pioneer services in France, Denmark, Canada, Australia, and the U.S.A., are clearly relevant to the challenges which still face the British psychiatric services. Others, such as the account of the highly commendable but still quite rudimentary service which is being created in the teeth of formidable difficulties in Sarawak, and that of community psychiatry in Israel, are less

obviously relevant to our own circumstances; nor, indeed, are the rather extensive discussions of attributes of contemporary American and Soviet psychiatry which are clearly related to the socio-economic conditions and social philosophies of these two countries.

It is certainly arresting to learn that whereas in the U.S.A. nearly every other hospital bed is a psychiatric one, in the U.S.S.R. psychiatric beds account for only one in eight of the total; but this at once excites our curiosity about such unanswered questions as whether there is a lower prevalence rate for psychiatric illness in the latter country, and whether the emphasis on community care which the Russians have built into their treatment services makes a significant difference to the outcome of mental illness. The description of a new pattern of medical care is often interesting in itself, but it invariably provokes a desire for objective evaluation of its effectiveness. Enthusiasm is an admirable and perhaps necessary characteristic of innovators; the majority, but by no means all, of the contributors to this book have realized that self-congratulation is not an adequate substitute for a candid appraisal of results.

There are some particularly valuable reviews and essays among the book's 42

chapters. Both clinicians and research workers will mine with profit in the papers of J. K. Wing, E. M. Goldberg, and Douglas Bennett on the care of schizophrenics, and that by A. Kushlick on a comprehensive service for the subnormal. M. M. Glatt contributes an excellent chapter on alcoholism which is marred only by his failure to do justice to Scottish research and clinical reports of recent years. Two chapters on hospital administration (unaccountably placed in different sections of the book) discuss this topic respectively from the point of view of a clinician, Dr. B. M. C. Gilsenan, and an experienced administrator, Mr. T. D. Hunter: the latter chapter is particularly impressive in showing how thoroughly a lay administrator can grasp both the therapeutic aims of social psychiatry and the changes in administrative organization which may be required fully to achieve these aims.

One could continue to single out many more chapters for special mention: there are papers here which will be of particular interest to psychiatric nurses, to the hospital junior doctor, and to the sociologist. Above all, however, the volume is a valuable reference work for clinicians and administrators who carry the responsibility for conducting community mental health services and who wish to keep informed of the latest developments in this field.

G. M. CARSTAIRS.

Fungal Infections of the C.N.S.

Mycoses of the Central Nervous System. By Bernard F. Fetter, M.D., Gordon K. Klitworth, M.D., and Wilson S. Hendry, M.D. (Pp. 214 + vii; illustrated. £5 2s.) Edinburgh: E. & S. Livingstone, 1967.

This book throws a lot of light on an obscure corner of pathology. It is well organized into two introductory chapters, followed by chapters for each of eleven individual mycoses (arranged alphabetically)—a composite chapter covering 14 rare mycoses—and three appendices. The latter list a classification of fungi incriminated in disease of the central nervous system, a list of references to staining techniques, and a classification of fungal neuropathogens seen in histological sections and proved culturally.

Each of the chapters on an individual mycosis opens with a general account of the discovery and distribution of the fungus and its usual clinical presentation. Within the nervous system the incidence, source of involvement, clinical manifestations, cerebrospinal-fluid findings, course and treatment, tissue reactions, and practical identification in tissues are systematically presented. A comprehensive list of references (293 in the case of cryptococcosis), including non-English sources, concludes the chapters. There

are 157 black-and-white photographs. Fungi stained by silver methods lend themselves to this and are superb. Other illustrations showing microscopic, macroscopic, and radiographic appearances are of uniform excellence. The four coloured figures are sensibly used to show pigmented fungi and the fluorescence of *Cryptococcus neoformans* after staining with acridine orange.

The compilation of such data will contribute to further research into how fungi take advantage of altered immunity to invade the tissues. As the authors point out, the rise in incidence of some mycoses has coincided with the use of antibiotics, steroids, cytotoxic drugs, and deliberate immunosuppressive techniques. Inside the nervous system cysts, abscess formation and granulomata, meningitis, or thrombosis and infarction (following invasion of blood-vessel walls) are the range of reactions to the various fungi, but an interesting point mentioned is that patients with cryptococcal meningitis have been shown to have alcohol in the spinal fluid due to the presence of the enzyme alcohol dehydrogenase.

These members of the department of pathology at Duke University Medical Centre, North Carolina, have done a thoroughly competent job in collecting and presenting all the data at present available relevant to fungal infections of the central nervous system. Much of the material appears to be their own,

although their names do not appear among many references listed. In the foreword Dr. N. F. Conant remarks that the "identification of the specific fungal etiologic agent by its appearance in tissues demands experience that can be obtained only by having had long and intimate contact with both the clinical and laboratory aspects of fungus infections." With this not inexpensive but compact volume to hand the rather less experienced pathologist or clinician may hope to diagnose the case of central nervous involvement by fungi when it presents.

KENNETH R. HILL.

Help towards Solving Problems of the Disabled

Equipment for the Disabled. An Index of Equipment, Aids and Ideas for the Disabled. 2nd edition. Edited by Margaret Agerholm, M.A., B.M., B.Ch.Oxon. (4 loose-leaf volumes; illustrated. £7 7s.) London: National Fund for Research into Crippling Diseases, 1967.

The first edition of this manual appeared in 1960 and was well received, for it provided information both for disabled patients and

those professions concerned with their management or welfare which had been difficult to obtain elsewhere.

The success of this venture by the National Fund for Research into Poliomyelitis and Other Crippling Diseases can be judged by the appearance of this greatly enlarged second edition seven years later. The book is divided into the same 17 sections, covering house adaptations, beds, chairs, wheelchairs, hoists, bed-table, communications, upper-limb prostheses, aids for eating, personal toilet, clothing, household equipment, cooking, aids for the disabled mother in child care, hobbies, walking aids, and invalid transport.

The sections on personal toilet, household aids, beds, and transport have been greatly enlarged. The new binding with its four-ring looseleaf cover is an improvement on the spiral spring holder of the first edition, which tended to perforate the pages. The general layout is excellent, the illustrations, photographs, and descriptions of the aids being clearly presented and simply described. The prices, where relevant, are given at the end of each section, so that variations can be catered for without amending the original illustration, but an approximate idea of cost would be an advantage on each page. The section on bathroom facilities in "house layout" is disappointing—no mention is made of showers, and details of hoists suitable for getting severely disabled patients into a bath would be welcome.

This book is an essential text for anyone, medical or lay, who has to deal with disabled people and should have as wide a circulation as possible. In particular, it is hoped that the attention of local authorities will be drawn to it, to show what can be done and to remind them of the wide powers permitted them in solving the manifold and complex problems disability presents.

The medical editor is to be congratulated on what must have been a herculean task of assembly, and also all the hospital departments and firms that have provided details of their equipment. It is to be hoped that they will not be so exhausted by their labours as to rest too long before preparing the next edition, as new ideas are constantly being developed. Such a compendium will itself inspire others to renewed efforts to solve the outstanding problems of living with a disability.

C. WYNN PARRY.

Full Story of Cardiac Pacemakers

Cardiac Pacemakers. By Harold Siddons, M.Ch., F.R.C.S., and Edgar Sowton, M.D., M.R.C.P. (Pp. 331+xvi; illustrated. \$16.75.) Springfield, Illinois: Charles C. Thomas. 1967.

This monograph written by two of the world's leading authorities on cardiac pacing is one of the most up to date and complete reference works on this important subject available. The contents include a historical review of heart block and defects of the conduction system followed by the aetiology, clinical presentation, and drug treatment of this condition. Subsequent chapters deal with short- and long-term pacing and discuss in great detail the practical application and management of the various methods of electrical

stimulation of the heart. There are 896 references and a most excellent appendix with full particulars of commercial pacemakers with their circuit diagrams and electrical characteristics.

The first chapters contain a detailed description of the aetiology and clinical and haemodynamic changes associated with heart block. This is followed by a critical review on the values of drug treatment apart from pacing the heart in this condition. It is probably right to say that all centres responsible for treating patients following myocardial infarction should have available facilities for short-term pacing, should the occasion arise, and the chapters in this book describing this can be usefully used as a practical guide. Long-term pacing with implanted pacemakers has to be undertaken by specialist surgeons, but these chapters can be read by all cardiologists with profit.

The authors must be congratulated on producing this first-class monograph which will be of the greatest value to cardiologists and all those involved in any way with the treatment of heart block. No cardiac department can afford to be without it.

J. P. SHILLINGFORD.

Irrecoverable Renal Failure

Renal Transplantation. 2nd edition. By Roy Yorke Calne, M.A.(Cantab.), M.S. (Lond.), F.R.C.S.(Eng.). (Pp. 220+ix; illustrated. 63s.) London: Edward Arnold. 1967.

When the first edition of this monograph appeared four years ago the author could not claim much personal experience of human kidney transplantation. Indeed, at that time it was necessary to convince many internists and nephrologists, especially in the United Kingdom, that intermittent dialysis, usually haemodialysis, was not necessarily preferable for the management of patients with severe irrecoverable renal failure. The situation has since changed so that it has now been possible for Professor Calne to collate his own experience with that of others in Australia, Belgium, France, Great Britain, and the U.S.A. and for him to be reasonably able to state in his concluding paragraph that we are now in a position to offer patients a good chance, possibly years, of tolerable life.

At the present time the success rates in the most experienced centres, judged by effective function of the transplanted kidney after one year, are approximately 70% when living related donors are used. As yet, however, the success rates are generally not nearly as good when organs from unrelated or cadaver donors are used. But with practical advances in tissue typing, provision of facilities for adequate intermittent haemodialysis (and possibly peritoneal dialysis) before and, when required, after transplantation, and the development of more efficient and less toxic means of immuno-suppression such as anti-lymphocytic serum it should not be unreasonable to expect significantly better results both with living related and unrelated or cadaver donors.

Professor Calne provides clear and concise accounts of these and many other of the problems that have to be resolved before kidney transplantation becomes a straightforward and

common surgical exercise, and has omitted little of relevance. Any renal unit contemplating a transplantation programme would be well advised to have a copy of this volume readily available for use by its medical and surgical staff.

RALPH SHACKMAN.

Otolaryngology

A Synopsis of Otolaryngology. 2nd edition. By John F. Simpson, F.R.C.S., Ian G. Robin, F.R.C.S., John C. Ballantyne, F.R.C.S., and John Groves, F.R.C.S. (Pp. 529+xv; illustrated. 52s. 6d.) Bristol: John Wright. 1967.

Otolaryngology is a rapidly expanding subject, short of practitioners, and is neglected by many British medical school curricula. Consequently, not only are students and general practitioners ill-served in the diagnosis and management of many common disorders, but few are stimulated to undertake specialist training. This synopsis is not designed for non-specialists but contains much information that would be of value to them.

In my view, synopses are to be deplored, for only selected information is provided in note form which makes for difficult reading, and such a dogmatic standardized treatment of the subject merely encourages learning by heart and fails to interest the reader. Much interesting theory receives scant mention, and concepts cannot be fully and logically developed. The absence of detailed surgical technique and reference lists must limit the book's usefulness for the postgraduate student.

However strong the objections, synopses are frequently bought and used for quick reference and revision in preparation for examinations (in fact, examinations are the reason for these shortened texts). In this case the authors' primary intention is to provide information which is suitable for higher diplomas. They have done it within the limits of inevitable cataloguing, for the subject is comprehensively surveyed, well illustrated, and almost up to date in every respect. The frequent drawbacks of multiple authorship are minimized, for each author intrinsically belongs to one school of thought—namely, that of St. Mary's Hospital in the first instance and that of the Royal Free Hospital in the second.

For those postgraduate students requiring potted information this work will fulfil almost all the requirements, but in no way does it replace the larger texts, monographs, or careful reading of specialist journals.

J. D. K. DAWES.

Autoimmune Disease

Autoimmunity. Clinical and Experimental. By J. R. Anderson, W. W. Buchanan, and R. B. Goudie. (Pp. 485+xv; illustrated. \$19.50.) Springfield, Illinois: Charles C. Thomas. 1967.

As one would expect of these authors, this book is lucidly written, sound, and critical. It deals with the more clinically important and well-established examples of autoimmune disease, but omits, as the authors concede in their foreword, a number of con-

ditions, such as Crohn's disease, male sterility, exfoliative dermatitis, and so on, whose autoimmune basis is still in doubt. This unadventurous attitude, though it makes for brevity and practicality, also means that the treatment is a little staid and conventional.

The first section, after a rather breathless synopsis of general immunology, includes a clear discussion of autoimmunity and the mechanisms of its production; subsequent chapters deal with the thyroid, stomach, adrenal, nervous system, kidney, colon, muscle, heart, and liver. The last section includes rheumatoid arthritis and disseminated lupus erythematosus with allied conditions. The pathology in particular of all these conditions is admirably dealt with. It is unfortunate in so soundly written a book that it is not completely up to date. Although one cannot fault it as a background review of the subject, there have been advances and clarifications—which it would be both laborious and invidious to note individually—since early 1965, which (from a cursory search through the references) would appear to have been the time of going to press. Though the tribulations of editors and publishers are innumerable, this seems too long an interval in a subject developing as rapidly as autoimmunity.

The illustrations, almost all of histological sections, are well selected and reproduced. There is still some doubt in my mind whether even the best monochrome illustration is really more than something to break up the page; and these must clearly account to some extent for the rather excessive price of this volume. But for those who are less lukewarm about pictures, the ones in this book are superior to those of any other book of its kind which I know.

Readers would be well advised to read the general editors' foreword after the text (if at all), since it contains an uncritical and inaccurate account of many aspects of autoimmune disease—for example, the remarks on damage by antithyroglobulin antibody in thyroiditis and on sensitivity to immunosuppression as a criterion for an autoimmune disease, which are contradicted or modified by more sophisticated discussion in the text.

The controversy on whether "autoimmune" conditions should really be called

"autoallergic" conditions has not affected the writing of this book, which may or may not be a pity.

P. G. H. GELL.

New Work in Ophthalmology

Advances in Ophthalmology. Vol. 18. Edited by M. J. Roper-Hall, H. Sautter, and E. B. Streiff. (Pp. 248; illustrated. sFr./DM. 68.) New York and Basel: S. Karger. 1967.

The eighteenth volume of *Advances in Ophthalmology* contains several articles of considerable interest. The first, by I. H. Leopold and A. H. Barnert, of New York, is a long account of the value and dangers in the use of the corticosteroids in ophthalmic diseases. The effect of these hormones, used both topically and systemically, on inflammatory diseases is undoubted and frequently dramatic; but due attention is given not only to the systemic complications which may arise with their administration by mouth but also to the ocular complications which may result from their topical instillation, whether it may be the encouragement of an active infection or the development of a complicating cataract or glaucoma.

The second, by C. A. Stucchi, of Lausanne, is an assessment of the present position of keratoplasty, particular attention being given to the use of preserved grafts and the social value of eye-banks. Then follows an experimental assessment by J. Draeger and F. Becker, of Hamburg, of the electronic applanation tonometer introduced by Mackay and Marg in 1959 in California. It will be remembered that this useful instrument, which takes continuous readings for tonography, eliminates the small errors in this type of tonometry by the use of a small central plunger surrounded by a "guard-ring" in such a manner that the factors of surface tension and deformation of the cornea are effective on the outer guard-ring and not on the tonometer itself, so that the Imbert-Fick law is applicable. A final article by Elisabeth Meier, of Basel, deals

with the intracapsular mechanism of lenticular accommodation.

STEWART DUKE-ELDER.

Highlights in Surgical History

Great Ideas in the History of Surgery. 2nd edition. By Leo M. Zimmerman, M.D., and Ilza Veith, M.A., Ph.D. (Pp. 587+xii; illustrated. 24s.) London: Constable. 1967.

This is a revised edition of a book first published in 1961. Though the authors state that it is neither a complete nor a conventional history, it is certainly an excellent and readable survey of the progress of surgery from the dawn of history to the end of the nineteenth century.

It portrays "a gallery of great surgeons," ranging from Hippocrates, Galen, and Celsus, through the backward times of the Middle Ages, and giving interesting and instructive accounts of the outstanding surgeons of the eighteenth and nineteenth centuries. Some little-known surgeons are included, as, for example, Caspar Stromayr, who was the first to differentiate direct from indirect inguinal hernia in his *Practica Copiosa*, written in 1559. In the chapter on Marion Sims the authors include a short account of the most distinguished early American surgeons.

Interest mounts as we approach the Listerian era, and the book finishes with descriptions of the work of Victor Horsley and Ferdinand Sauerbruch. There are very brief accounts of more recent developments in neurological and thoracic surgery. One would have liked to see some mention of Owen Thomas, and Lawson Tait and William MacEwen deserve more than the very brief reference accorded them. However, one hopes that the authors may compile a similar volume dealing with the surgeons who have pioneered modern surgery through the last 80 years. Such a volume would surely be welcomed.

I cordially recommend this book to all young surgeons and to medical students, for it is a valuable volume and the price is very reasonable.

ZACHARY COPE.

Books Received

Review is not precluded by notice here of books recently received.

GENERAL PRACTICE OBSERVED

Extended Use of Nursing Services in General Practice

J. WESTON SMITH, M.B., CH.B., D.R.C.O.G., D.A.; E. M. MOTTRAM, S.R.N.

Brit. med. J., 1967, 4, 672-674

Nursing Services in a General Practice—An Experiment

Our practice comprises a partnership of two doctors with a list of about 5,500 patients during the first nine months of this year. The practice covers a radius of about 5 miles (8 km.). We were faced with a difficult situation at the beginning of the year, as it was obvious that a major outbreak of measles was imminent, in addition to the other common infections.

There seemed to be three main problems. Firstly, the practice is situated in a "designated" area which is rapidly expanding because of overspill. There are more new patients than can be comfortably accepted if a satisfactory standard of medical care is to be maintained. Secondly, there is a large rural area to be covered, but both the partners are also heavily involved with hospital work. Thirdly, there is a lack of suitably experienced doctors willing and able to undertake this wide spectrum of work.

It was thought that the scope of work, both in hospital and in the care of greater numbers of patients, could be done efficiently and properly provided that time was not wasted with minor problems, especially unnecessary visiting and revisiting and routine procedures in the surgery. Nevertheless, the ordinary patient is not in a position to know whether a particular situation needs the visit of a doctor or not. The Ministry of Health circular puts the onus of decision on the doctor, who often has only the verbal history of the patient, possibly second-hand from a neighbour or relative. Further, revisiting is desirable and necessary in certain cases where the progress of the patient needs to be assessed professionally and skilfully. There was one more disquieting factor; because of the good will in the practice, we found the patients, knowing we were working under strain, often helped by not asking for a visit but for advice and a prescription to be left; we felt that this was not a desirable practice.

Hence we decided to appoint an experienced nurse to help in the clinical work of the practice for about 20 hours weekly, with the following duties:

- (1) The reception and assessment of requests to visit and other messages, from 8.45 to 10.30 a.m.
- (2) Visiting new calls after consultation with the doctors in those cases where there was doubt about whether a visit by doctor was necessary.
- (3) Immunizations and desensitization procedures during surgery.
- (4) Assistance at the antenatal clinics.
- (5) Revisits and routine visits to elderly and disabled people.

It was obviously necessary for the nurse to have a fairly wide experience, preferably with outpatients, and to be a car driver. From the beginning we decided to employ her for three and a half hours in the morning and two afternoons a week, and to pay her top salary scale and a car allowance on a per mile basis.

Instructions to the Nurse

The nurse received all the incoming requests for visits and advised and recorded them. Our patients with problems have always been able to speak personally to the doctor; and in these cases, or when the nurse was in doubt, the nurse was instructed to put the call through to the doctor. After conferring with the partners she visited the requests for first calls. The doctors meanwhile went on to their hospital duties. If in her opinion any patient needed immediate attention the doctors could be contacted at the hospital.

All patients visited were to have their temperature and pulse recorded, together with a short clinical history, followed by the nurse's impressions and suggestions. This was all to be recorded in a report book which was to be kept in the surgery. The nurse would then deal with the request in one of the following ways:

- (1) In the nurse's opinion a doctor's visit was not necessary, nor was it necessary for the patient to visit the doctor at his surgery, and the household could be reassured.
- (2) A doctor's visit to the house was not necessary, but the patient was fit to visit the surgery and an appointment was arranged.
- (3) Common-sense measures were suggested or the nurse would recommend some mild medicine be prescribed by the doctor—for example, a simple cough linctus or antacid.
- (4) If a common infection was found or suspected—for example, measles—the nurse was usually able to make a provisional diagnosis and report it to the doctor, who would visit the patient when he was in the neighbourhood.
- (5) If pyrexia was present or other disquieting symptoms in the absence of a known epidemic condition, the nurse advised the household that the doctor would be calling later on.
- (6) The doctor was contacted urgently.

It was emphasized to the nurse that if the family in any way indicated they would like the doctor to call personally this must be done. In fact, in the course of over 700 calls this did not happen once, and in only three cases was a call later requested for the doctor personally to visit after the nurse had called. In each of these three cases no reason was found to disagree with nurse's assessment of the case, neither did the patients want anything apart from reassurance.

The numbers in Table I exclude all visits requested after 10.30 a.m. and all midwifery calls.

TABLE I.—Number of Visits Made

	Nurse	Doctor 1	Doctor 2
Total No. of visits January to October	744 + 41 (2 in 1 house)	800	285
Total No. of first visits	537	560	228
" " " revisits advised by nurse	86	10	57
" " " " " " doctor	111	230	No. of visits not recorded
Emergency visits during surgery	10	first revisits	

We found that if a conference was held at about 12.30 p.m. the cases could be discussed and action agreed on. Occasional checks were made by the doctor on families visited if further reassurance seemed necessary or where there was an element of doubt. This was found to be increasingly unnecessary as the scheme began to be known to the patients. It was soon found that there was a great preponderance of nurse calls to young children and revisits to elderly people. This is, of course, in line with the general visiting pattern of general practitioners, but the doctor visits proportionately increased in the age ratio of 10 to 60. It was our impression that, as the scheme became more widely known, the threshold at which a visit is requested has become lower and a visit of the nurse is specifically asked for.

The nurse's 785 visits were made up as follows: 485 to children under 10, 133 to patients over 65, and 167 to others. From the report book we were able to compile Table II, which shows the numbers of first visits performed by the nurse and roughly the type of case.

TABLE II.—*First Visits Made by Nurse*

Common infections, measles, mumps, chicken-pox, etc. . .	187
Rashes without pyrexia	19
Catarrhal colds and coughs without pyrexia	62
Infections with pyrexia	96
Diarrhoea and vomiting	66
Others—e.g., injury, social, oedema, abdominal pain, history taking	97
Emergency	10

The method of working of the two doctors differs. Doctor 1 is the elder, with a much larger proportion of older and chronic sick patients, and it is from him most of the revisit requests emerge. Doctor 2 has a number of hospital anaesthetic appointments together with the bulk of the practice midwifery (about 114 cases per annum); hence most children under the age of 10 years are in his care, and it is from him that the highest proportion of first nurse visits emanated. The proportion on a typical spring day would be: three first nurse visits requested by Doctor 2, one or two nurse revisits requested by Doctor 1, one nurse revisit, and one nurse routine visit. Thus a very high proportion of patients anxious about their own or their children's health do not actually appear to need a personal visit by the doctor. This is emphasized by the fact that there was not one complaint about the scheme. However, on many visits the nurse was asked to see other patients at the same time; she was able to do this without undue stress, though this may be a source of minor irritation to a general practitioner with a full visiting-list.

Of 440 first visits to children only about 10% required a doctor's visit that day. The period surveyed covered a parallel epidemic of measles and chicken-pox, and here the nurse's help proved invaluable. The confirmation of the condition with general common-sense advice, to settle with the later visit by the doctor, proved to be very popular with all classes of patients. Another fact was the early recognition and treatment of enteritis in infants and the institution of the standard regimen.

Questions to Patients

It was appreciated that many people who had been used to sending for a doctor might not accept the visit of a nurse, however well trained she might be. Hence it was thought essential

Replies to Questionary

	Yes	No
Did you find it a help for a nurse to advise you whether a visit by doctor was necessary?	179	3
Did you find the visit of nurse helpful?	185	2
Were you satisfied with the result of the visit?	186	2
Did you later visit doctor?	63	120
Have you any further suggestions?	33	congratulatory replies, 1 unfavourable

to find out the reaction of the various patients. A questionnaire was sent to every household visited by nurse. At its head was a letter outlining its purpose, and a dotted line underneath indicated that it could be torn off and returned anonymously if so desired.

A total of 260 copies of the questionnaire were sent out to all the households visited and we received 189 replies, although the postage was not prepaid.

The answer that exceeded our expectations was under the heading "suggestions." About 26% of the households visited had something to say on this subject, and their comments show there is a very definite demand for this type of service. There were many comments on the great help given; several people said that the National Health Service would be greatly improved if the practice were extended. In particular we found that there is a need among mothers of infants and young children for expert advice about when to summon the doctor, the opinions of neighbours and relatives being notoriously unreliable. We found that elderly patients are glad to be revisited, but like a doctor to see them the first time. One other fact emerged—families with problems appreciated the visits, as they knew they had time and opportunity to discuss apparently trivial matters with which they would not bother the doctor for fear of wasting his time. Nevertheless, knowledge of these factors often helped in assessing an individual patient. On the other hand, we found that problem families were best left to the county authorities, who have the machinery and time to deal with the many difficulties involved.

We strictly excluded nursing procedures on the district, as it was thought that the county district nurses might think that this was an unwarranted intrusion into their province. As a general rule, therefore, the nurse did not visit any family which was in the care of a district nurse. On the other hand, we found that she could complement the work of the health visitors, especially with premature babies and congenital defects; these she could weigh regularly at home and take prescriptions ordered by the hospitals; moreover, she could give courses of immunization at home.

Developments

As the scheme developed considerable changes were made. Firstly, we realized that the initial time allocated to the nurse was grossly inadequate, and this was increased to about 27 hours. Since 1 October 1967 we have acquired a new partner and over 2,000 new patients, and we envisage that there will be enough work for a full-time nurse. Secondly, we found the use of a trained nurse to assess incoming calls invaluable, and we soon found that patients were asking specifically for the nurse.

One of the more worrying happenings in general practice is the apparently urgent call during a busy surgery. During the period under review the nurse went out immediately to assess the situation with instructions to report at once in 10 cases. The final assessment of these was as follows: two coronary thromboses (doctor and ambulance were sent for); two falls (sent to hospital); one appendicitis (doctor visited after surgery); two fits (first aid, and doctor visited later); two epistaxes (first aid); and one sudden death (arrangements made).

Like many others, we also found that there are a surprising number of duties apart from immunizations and routine injections for a nurse to do during surgery—for example, routine blood pressures, skin reaction testing, detailed history taking, and ear syringing. Moreover, during antenatal clinics routine blood pressures, testing of urine, weighing, and the preliminary medical history could be done by nurse before the patient was seen by the midwives or doctor. We found that by restricting her duties to these items the relations between the different types of nursing staff were happily maintained.

We were anxious about a possible tendency to prescribe appetite suppressants without a careful follow-up. Accordingly we decided to prescribe only a week's supply, and that the nurse should do weekly weighings; further supplies depended on a gradual loss of weight. To our surprise, a weight-losing group soon developed, and we noted that patients in this group were voluntarily giving up taking the pills and often losing weight faster than those on suppressants. Two full clinics have now formed. We are also proceeding with the formation of an anti-smoking group, and the demand for this is already high.

Discussion

It is too early to evaluate all the implications of this project or to assess accurately the advantages and dangers inherent in its application. We think it is sufficiently important, however, to put our experience on record, realizing that there must be critical comment and observation. We think there is an opening in a practice such as we have described for a full-time nurse carrying out the duties we have outlined. This is no position, however, for the newly qualified State-registered nurse. At least four years' post-qualification experience is necessary, preferably up to the standard of staff nurse or sister in a casualty outpatient department or in a ward for acute cases, where not only ill people are encountered and have to be assessed but the problem of human relationships between the profession and the patient together with their relatives is of paramount importance.

We think that the scheme shows that there is a much wider field of work for the experienced nurse than has been thought possible in the past. The S.R.N. of today has a wide education and her training takes her a long way beyond the traditional nursing procedures; one of the criticisms of nursing today when a nurse leaves hospital is that a large amount of her time is occupied in nursing procedures which in hospital would have been left to nurses in their early training period. We think that the modern nurse is in a position to assess whether a patient is ill enough to need the visit of a doctor; in other words, we are placing her in the position of a sister with a responsible hospital position. It was noticeable during the nine months that the main calls fully dealt with by the nurse concerned patients at the extremes of age, and we found that in the nurse's opinion working men and women who requested a visit usually needed the visit of a doctor.

We have found in practice that the whole concept is acceptable to the majority of our patients. It is most important for patients to know that the nurse is not a substitute for the doctor, and in fact is trying to help the latter arrive at a decision. In fact we found that the nurse is far more apt to err on the patient's side than on the doctor's. Nevertheless, many people may query the possible dangers of using nurses for first visits. There is, on the one hand, always the possibility of the mistaken assessment of the case; on the other hand, this is so with any doctor, for no professional person is free from errors of judgement. Looking back over the past, we think that the incidence is not likely to be higher in the case of an experienced nurse. We have taken the attitude that the partners are responsible for all the acts of the nurse, but it is the view of the Royal College of Nursing that the nurse should be indemnified and protected in the event of litigation on her own account; this, we understand, is possible in a similar manner to the medical profession.

We would like to emphasize that we think the following points are essential:

(1) That the employing doctors satisfy themselves, by inquiry and personal assessment, of the ability of the nurse to undertake this type of work.

(2) That the written report *must* be entered of each patient visited, together with the temperature, pulse rate, full history, and the nurse's opinion.

(3) That there should be personal consultation and agreement between the doctor and nurse about the conduct of each individual case.

Unless the above criteria are strictly observed a disastrous situation may occur at any time. If this type of scheme is used as a form of cheap medicine, as a barrier between the patient and doctor, or is embarked on without careful thought and planning, we believe it a retrograde step. In practice it is our impression that far from lessening the amount of work done by doctor the amount of consultative work has actually increased; this, however, can be only a subjective impression owing to the increasing number of patients, but it is already apparent that the total travelling time by the doctors has already diminished.

We think it is essential for a full secretarial service to be maintained, and that the nurse has the same facilities as the doctors for documentation and dictation of letters. It is also extremely important that the correct relationship be maintained with the local health authorities, and for this reason no nursing procedures are undertaken on the district. The attendance of midwives at the antenatal clinic is encouraged by the local health authorities, and on these occasions the work of the nurse is restricted to initial documentation and history, urine tests, and blood pressure estimation. In our opinion the nurse in the circumstances described is best employed direct by the practice rather than by the county service. On the other hand, the nurse must make herself fully conversant with all the services available through the county.

At present nurses employed in this way would seem to forfeit their superannuation rights under the National Health scheme, and this would seem to merit critical attention. From the practical standpoint the hours worked are especially suitable to part-time nurses—that is, 8.45 a.m. to 4 p.m. from Monday to Friday—and may tap a source of nursing strength hitherto unavailable.

We feel certain that in this field of work there is a great future, and that the nurse entering it will at some time in the future have special training—in fact this would seem essential. We think that two months' instruction in the methods of general practice and the various forms used by the executive council, followed by four months' attachment to a suitable practice with an assessment at the end, might merit serious consideration.

Summary

Over a nine months' period a State-registered nurse has been used for helping in the clinical work of a general practice in a semirural area with about 5,500 patients. Provided a nurse with the right temperament and extensive clinical experience is obtained, and suitable safeguards are used, we think that she can be used for making first visits to patients, and the replies to a questionnaire sent to the patients showed that most patients agreed and welcomed the scheme.

Our thanks to Dr. C. H. Goodliffe, the senior partner, for his wholehearted co-operation in the study and the use of his figures, and to Mrs. Beryl Weston Smith for the preparation and typing of the paper.

CONTEMPORARY THEMES

Medical Partnership: Minister's Lecture at Glasgow

A Maurice Bloch Lecture was delivered by the Minister of Health at Glasgow University on 6 December.

Mr. ROBINSON's title was "Partnership in Medical Care." He began by referring to his recent statement in the House of Commons [*B.M.J.*, 11 November, p. 367] that the Government intended to review the administrative structure of the National Health Service and, if necessary, to reconstruct it. He emphasized that they did not in any sense feel that the National Health Service had "failed." Nevertheless, the statutory apparatus—which had been basically unchanged since 1948—had been outgrown by its service content. Medicine changed, evolved, and developed, and hence required an organization which not only permitted but actually promoted change.

"Phase I" of the N.H.S.

Discussing what he called Phase I of the National Health Service, Mr. Robinson said that the objective of the Service was firmly set forth in the wartime Beveridge Report, which aimed at producing a comprehensive blueprint for the Welfare State, and assumed that a National Health Service would be an essential part of this blueprint. Taking up the idea, the Government of the day produced a White Paper in 1944 which announced the intention to establish a comprehensive health service for everybody in Britain. Nevertheless, the founding of the National Health Service was evolution, not revolution; thus the White Paper spoke of a "comprehensive service for all regarded as the natural next development."

Organizationally speaking, what had happened in 1948 was that a uniform organization was imposed on services which were already there, though not all of them everywhere or available within the individual's means. The tripartite structure of the Health Service established by the Acts of 1946 and 1947 reflected a concept of three interdependent but separately managed streams of care for the community and an implicit assumption that relationships would not change. Looking back, Mr. Robinson continued, this was a curiously static conception, as if the new form of management need only attempt the organization of services as they then saw them.

Need for Co-operation

The need for co-operation had been reviewed as early as 1952 by a Committee of the Central Health Services Council. Its recommendation had been to establish standing joint liaison committees both for general and for special purposes, but again it had seemed unaware of the organic nature of the enterprise. Having no executive powers, the usefulness of these liaison committees was limited, and those few that were established took up a lot of time.

The committee set up to inquire into the cost of the N.H.S. (the Guillebaud Committee) had in the nature of things to consider the structure of the Service. In essence, its finding was that the organization had only just settled down in the eight years of its existence and that it was far too early to

make a change. This committee set the tone for most of the thinking about structure for many years. While it was perhaps unfair to criticize the committee now when circumstances had changed so radically, the fact remained that the doctrine "When it is not necessary to change, it is necessary not to change" had inhibited and perhaps stultified thinking. But people were not ready then to think of entirely new machinery, only permutations of the old. In respect of particular services, it became evident that there was a case for unifying the three branches, but the committees reviewing these particular services recognized that they should not be split off from the general Health Service structure and that, given that the general structure was tripartite, the particular service also had to remain so. Chapter and verse could be found in the Cranbrook Report on Maternity Services—of which the Scottish equivalent was the Montgomery Report—and the Report of the Royal Commission on the Law relating to Mental Illness and Mental Deficiency.

Continuing, Mr. Robinson pointed out that the question of an entirely fresh approach to administration of the Health Service had been reopened by the Porritt Report in 1962. This report had come out uncompromisingly for the principle of area health boards, which would deal with all aspects of the Health Services, but it had made no attempt to define the size of areas or the composition of boards. The reasons which had moved this committee were those of fulfilment: for the general practitioner to be able more fully to realize his capacity and his potentialities by extending his access to the specialized services of the hospital, though consultants were to remain responsible for hospital work.

The committee also wished to tap the special expertise of the medical officer of health and to give him a wider sphere in which to exercise his talents by making him a consultant in social health in an appropriately broadened department. This report was a turning-point, though he could wish that the committee had agreed on and said more about some very necessary changes in the organization of medical work in and out of hospital.

Among the many criticisms made of the Porritt Report it had been said that the report produced an idea and a philosophy, but in no sense a plan. "What was to be the geographical extent of the area health board? How was it to be governed? Was it not a self-defeating process to propose, as the report did, first unifying the administration of the services but then setting up three subordinate bodies under the area health board corresponding to the existing tripartite divisions?"

Is There an Alternative?

There was something in all of these criticisms of the Porritt Report, but they had missed the important point that the post-Guillebaud freeze had been thawed. Since then restructuring of the administration had been a frequent topic among those connected in any way with the Service. The medical profession had itself returned to this ques-

tion, and the *British Medical Journal* had produced a series of articles, now collected in book form under the title *Is There an Alternative?* The object of these essays, ranging widely as they do from almost pure organization theory to the possibility of a sweepstake to finance hospital services, seemed to have been to provoke people to think about the range of possible alternative structures. "If I may say so, this seems altogether helpful: there is not one, there are many possible ways of restructuring the Health Service."

Mr. Robinson then turned to what he called the realities of life for workers in the field which underlay this debate on the government of the Service. He pointed out that, firstly, a revolution had begun in general practice. Much of this had been carried out by the general practitioners themselves, and the changes had become so widely accepted that there was some danger of losing sight of their magnitude. Let it never be forgotten that group practices were a truly co-operative advance made by independent professional men of their own volition. They had come together to give better service to the public, and also to find a more satisfying professional and personal life. This was essentially a development which individual doctors must seek. The action of Government in such matters was necessarily limited.

Changes in General Practice

In the 1940s the general practitioner had often been isolated from professional contact and learned only from his own experience. Now, many of them were active in research, and far more eagerly took advantage of courses for postgraduate education. All were making increasing use of the diagnostic support facilities they could draw on from the hospitals. Secondly, the general practitioner was beginning to emerge as the leader of a team. Most local authorities had agreed that some at least of their health visitors, home nurses, or midwives should be attached to group practices rather than districts. This move had helped to make each member of the team more "productive" and to ensure a good two-way flow of information about cases in which both the general practitioner and the local authority department were interested.

Thirdly, there had been a quite remarkable upsurge of interest in the new opportunities offered by health centres. All these changes had been in the field; they had not been matched by any change in the structure. The conclusion was inescapable that the administrative apparatus must be clearly made to serve the needs of those who were actually doing the work.

A comparatively unnoticed development was the beginnings of a managerial revolution in health planning. The application of the principles of scientific management to the hospitals had raised some very big questions, and it had been realized that economy could often be best achieved by concentration. It was a very difficult matter to find the right blend between the managerial and the medical optimum; it must never be forgotten that good medicine must be humanely based on personal contact.

Best Features of N.H.S.

Mr. Robinson then turned to some of the best features of the Service which must be carried on into any new structure. The first and greatest of these was the partnership of the health professions. Despite all the demarcations of which he had spoken, a continuity in medical care had been preserved. The professions had never allowed their contract with one authority or the other to obstruct their acting together in the common cause. It was apt, he thought, that the President of the B.M.A. should have chosen for his text "One Profession, One Purpose." [*B.M.J.*, 15 July, p. 129.] These four short words reminded us that medicine was more than a science-based discipline: it was founded on the rock of an ethic.

One aspect of partnership which he hoped could be established on firmer foundations than in the past was the partnership between profession and Government. This relationship was critical for the success of any State-organized health service, but it had been bedevilled by the profession's suspicion of Government from the day more than half a century ago when the State had first entered the arena of comprehensive medical care. To-day the suspicion lingered, perhaps less among the rank-and-file members of the medical profession than among some of those who spoke for the profession in a representative capacity. There might have been sometimes partial justification for this, because suspicion soon became mutual, but he did not think that had been more than fleeting and occasional.

"The medical politician is expected, or believes that he is expected, to reflect the anxieties and frustrations, real and imagined, of those he purports to represent. In such a situation a politician, and I speak as one myself, is tempted to look for an easily recognizable scapegoat. To delve into and try to identify the root causes of frustration is an altogether more complex and possibly painful process. Furthermore, if such an exercise reveals causes that are internal rather than external the findings may not be too welcome. It is so much simpler to blame

the Minister and his department, or to suspect their motives."

The relations between the State and a distinguished profession could never be entirely smooth. Nevertheless, not only was the doctor's clinical freedom sustained as the inviolable rule of the Service but questions of remuneration (always a potential source of friction) had been handed over to independent bodies for consideration, subject to the Government's retaining, as it must, the ultimate right of decision. Despite these efforts, however, there was still not the relationship of mutual confidence between profession and State. Obviously they had failed to carry conviction, and he wished he could see why.

Many doctors might well recognize that the Minister's objectives were the same as their own—namely, to provide the best possible service the nation could afford and as quickly as a vast modernization programme permitted. Nevertheless, one looked almost in vain to see this attitude reflected in the official voice of the profession. To the public outside there appeared to be a state of antagonism towards Government. Every test of opinion, however, confirmed that the patients themselves simply did not share the misgivings of so many medical spokesmen. Hence in devising a new structure for the Service it was essential to do everything possible to promote the development of a genuine sense of partnership.

Health Service Management

Mr. Robinson preferred to think of Health Service management not as the place from which orders issued, but the forum where problems were thrashed out; where each point of view was put, the professional requirements, the needs of the community, and the financial restraints; where there was communication between the various groups concerned in sharing out resources; where information was gathered and pooled; where proposals could be framed in the light of every consideration; where agreed policies could be hammered out. The problems of the Service could be solved only if the pro-

fessions had a clear role in that process.

The planners they wanted in the Service were those who knew how to make common cause and partnership with the workers in the field. He would naturally like additional resources, but perhaps above all he would like 50 more men skilled both in medicine and the managerial sciences. More men were needed who were "health planners" as versed in that art as town planners were in their specialty. The Health Service needed some of the ablest men to come forward for such duties, centrally and locally, and to fill the group and divisional posts recommended in the two recently published reports on the organization of medical work in hospitals. They would find much scope for their talents, for the time was clearly past when individual skills sufficed for successful hospital work.

Concluding, Mr. Robinson offered a "friendly criticism" of the medical profession—that in their laudable concentration on "this patient here and this patient now," they had in general tended to neglect the question of general management of resources, and in particular what the businessmen called corporate strategy: "Where shall we be going in 5, 10, or 20 years' time, what kind of medicine will be practised, and what kind of environment shall we be working in?" He therefore applauded the setting up within the British Medical Association of a Forward Planning Unit under Professor Henry Miller. He hazarded a guess that fairly rapid moves would be made in the functional linking of the hospital and the community services. The general practitioner would give a new dimension to the concept of the all-round personal physician as group practice developed with nurses and doctors forming the group. Hospitals would become ever more sophisticated and intensive in their approach to treatment. Nevertheless, they would be places where people might go more often but would stay for a shorter time if they stayed at all. The hospital of the future was likely to function effectively only through its partnership with the group practices, with which it would form a complex for both curative and preventive work.

TOMORROW'S BUILDINGS**Thamesmead: First Phase of Community Health Service**

[FROM A SPECIAL CORRESPONDENT]

The overall proposals for the community health service at Thamesmead, the new G.L.C. development within the London boroughs of Greenwich and Bexley, have been described in other articles.^{1,2} A new stage in the project is marked by the current exhibition at the Building Centre, Store Street, London W.1, of the plans of Messrs. Derek Stow and Partners, architects and planning consultants for the health centres, of the first phase of the development.

The essential feature of the Thamesmead project is that medical planning should proceed step by step with overall planning from the very first stages. The aims of the medical plan are:

1. To provide the best possible health services economically feasible within the present structure of the N.H.S.

2. To enable medical, dental, and other students to see and partake in community health care.
3. To promote research and experiment into medical care and its organization.

"The original proposals" showed how these aims could be achieved by a network of health centres enabling doctors, dentists, nurses, and other health staff (whether under the local health authority or the executive council) to work effectively together and in association with the local hospital. The first two stages of Thamesmead, which are now under construction, will house about 10,000 people by the end of 1970 and lie entirely within the borough of Bexley. By 1981 a population of 58,000 is envisaged.

As it may be five years before any building can take place in the centre of Thames-

mead, it is necessary to provide comprehensive services as soon as possible. The proposals illustrated in the current exhibition are for a health centre to be built by the G.L.C. for the borough of Bexley under section 21 of the N.H.S. Act. As this may not be completed before the end of 1969, it is also proposed that a temporary mobile health centre be erected early in 1968; when the first permanent building comes into operation the latter could be moved to a new site in Thamesmead.

Principles of Buildings

The briefs for these two buildings were drawn up by the General Practice Unit at Guy's Hospital (Director, Dr. ROBERT SMITH) working in close collaboration with

the borough of Bexley and with the Medical Architecture Research Unit at Southend (Director, Mr. RAYMOND MOSS) and the General Practice Advisory Service (Architect, Mr. BRIAN BROOKES). None of the hospital services envisaged in the overall plan is now involved, but otherwise the brief reflects in miniature the ultimate aims of the project.

The design of the first building was influenced by a number of important factors:

1. The need to be self-sufficient, taking account of the possibility of some changes in function as the total pattern of health facilities grows.
2. The town-planning principle of segregation of pedestrians and vehicular traffic by means of a pedestrian deck at first-floor level: all traffic (but only a small number of pedestrians) will approach the building at ground level.
3. The site location (bordering on an artificial lake near one of the development subcentres) and size (rather less than the floor area required).

The architect's solution was to raise the main accommodation on a concrete deck to first-floor level (that is, pedestrian-deck level), leaving the ground floor for vehicle passenger entrance, service rooms, stores, and a pram park for the minority of pedestrians who approach from a near-by bus-stop and from the subcentre via the lake walk. Car park-

ing is provided at this level under cover of the pedestrian deck above.

Patients and staff arriving at this level can reach the main accommodation by means of lift or staircase, which discharges adjacent to the main pedestrian entrance at first-floor level. Immediately facing the patient on entry is the reception desk, which has visual control of the three sides of the square-ring corridor. After registering, patients wait in the adjacent general or dental waiting-rooms (which include a children's playroom) and are called down the east and west corridors respectively to consulting- and treatment-rooms.

Consulting-rooms

General consulting-rooms are served by a treatment room, specimen room, and laboratory; in addition, they share a supply store and disposal room with the dental suite. A small local waiting space is provided for patients passing from consulting- to treatment-room or—in the case of antenatal clinics—in the opposite direction.

Dental patients pass from the main waiting area, down the west corridor, where they are met by the dental nurse. After treatment they may return by way of the main entrance, or, if a general anaesthetic has been

necessary, they may use the exit adjacent to the dental suite, which is also used by the dental staff.

A separate exit for staff is provided by the escape stair in the north-east corner, allowing them to arrive or leave without passing the main waiting area (see plan).

It will be noticed that rooms around the perimeter are those requiring a view and natural light but no other special environmental requirements; rooms in the core of the building would not benefit from a view, but do require special ventilation of one sort or another. Neither the consulting-rooms on the east side, nor the dental surgeries on the north, are overlooked, since they face the lake.

The temporary mobile health centre has a demountable structure, consisting of four single-steroye timber units, each the size of a large caravan and containing part of the health centre accommodation, fully equipped. These units are simply carried to the site on a trailer, set down on their skids and connected by additional floor elements which form waiting and corridor spaces.

CONFERENCES AND MEETINGS

Operating-rooms a Century after Lister: B.M.A. Symposium

[FROM A SPECIAL CORRESPONDENT]

A Lister Commemoration Symposium on operating-theatre design was held at B.M.A. House on 8 December, under the chairmanship of the President, Mr. R. V. COOKE.

Opening the symposium, the Minister of Health, Mr. KENNETH ROBINSON, referred to Lord Lister as one of the twelve people who had done most to relieve human suffering. At the present time new hospital buildings worth £230m. were under construction. In the interests of economy, speed of construction, efficiency, and good design his Ministry was now developing standardized plans for operating departments, but this would not mean stagnation. Alternatives were provided, and designs would be continually brought up to date.

Concluding the opening addresses, Professor Sir HEDLEY ATKINS, P.R.C.S., outlined Lord Lister's long association with the B.M.A.—extending from 1863, the year after his qualification, to his death in 1912. Within a month of Lister's publication of his second *Lancet* article, in 1867, the Association had invited him to address their Dublin meeting. He became president of the surgical section in 1870, and first described the famous carbolic spray at the Plymouth meeting of 1871. Although relations with the B.M.A. were subsequently less good for a time—largely owing to the activities of the then editor of the *British Medical Journal*—amity was later restored, and a special Lister issue of the *B.M.J.* appeared early in the present century.

Wound Infection

The first speaker in the symposium itself was Professor R. E. O. WILLIAMS (St. Mary's Hospital Medical School, London), whose subject was wound infection. The overall incidence of this was about 6.7%, but this figure concealed wide variations between different hospitals and operations—from 1.8% to 17%, according to hospital, and from 1% or less for orthopaedic operations to 15% for gall-bladder surgery. Infection acquired in the theatre probably accounted for about 20% of all wound sepsis, though the proportion might be as high as 50% for prolonged thoracic surgical procedures.

The source of infection varied with the type of organism. *Staphylococcus aureus* commonly came from the nose or skin of the patient or hospital staff, and the carrier rate in patients rose from 35% to 50% while in hospital. Two per cent. of patients carried penicillin-resistant strains on admission, but the proportion could rise to 20% or 30% during a prolonged stay. Probably post-operative wound sepsis with *Staph. aureus* was commoner in patients who were or had been carriers; during prolonged operations some bacteria almost inevitably fell into the wound, and many of these were the patient's own staphylococci.

Three other organisms—*Escherichia coli*, *Pseudomonas aeruginosa*, and *Clostridium welchii*—could also cause self-infection. The major source was intestinal, but *Ps. aeruginosa*

bred in moist environmental reservoirs such as sinks, sluices, and humidifiers; to a lesser extent this was also true of *E. coli* and perhaps *Cl. welchii*. A study of 20 patients with postoperative gas gangrene had shown that 18 followed lower-limb operations, 11 of them amputations. The antiseptics used had been ineffective against clostridial spores, and no prophylactic penicillin had been given. *Cl. welchii* was normally present in the intestine, and operations on the upper leg were readily contaminated from the anus. By contrast, *Cl. tetani* infection was almost always due to faulty sterilization—often of dressings or glove powder.

Preventive Measures

Professor Williams concluded by recommending preventive measures—proper sterilization for tetanus, suitable antiseptics and chemoprophylaxis for gas gangrene, and careful control of humidifiers and other moist areas for prevention of pseudomonas or *E. coli* infection. *Staph. aureus* presented more complex problems involving control of carriers and skin spread.

Some of these were covered by the second speaker, Professor R. A. SHOOTER (St. Bartholomew's Hospital, London)—speaking on dispersal of bacteria—who suggested that adoption of the measures proposed by Professor Williams would reduce the incidence

of operating-room sepsis to 1% or less. Showers did not control this dispersal from the skin; greater numbers of bacteria were shed for one and a half hours after a shower, and the effect of adding hexachlorophane was inconstant. Ordinary theatre gowns did not reduce the number of organisms put out, though the level was low and perhaps immaterial except in high-risk operations. Special operating suits made from very closely woven material and, worn with plastic bags enclosing the feet and trouser-bottoms were more successful; ultraviolet light could also help, though it was not fully effective when used alone. A combination of both methods was best, probably because dispersal of bacteria-laden skin scales was prevented, and individual organisms penetrating the finely woven material were killed by ultraviolet irradiation. The special suits and plastic foot-bags also cut down bacterial dispersion from nurses compared with conventional skirts and gowns.

Dispersal from inanimate objects was another danger. In the case of sterile packs, it had been found that opening a single-layered wrapper threw bacteria from the outside into the air; these landed on the instruments in 132 out of 250 packs tested. Substitution of a double-layered pack reduced contamination to 1 in 100. Finally, trials of paper sacks (sealed by stapling) for removal of all contaminated material from operating-rooms had shown that no bacteria escaped on handling or even when the bags were dropped. The special routes for removal of contaminated material now incorporated in many new theatres appeared to be unnecessary.

Ventilation

Dr. O. M. LIDWELL (Medical Research Council) said that operating-theatre ventilation systems had so often been to blame for wound infection in the past that they were now commonly made the scapegoat. In fact the number of pathogenic bacteria likely to reach an operation site by the airborne route was very small—perhaps one or two organisms—but even this might be enough to cause infection in the presence of sutures or other foreign bodies, or microscopic areas of dead tissue, or blood clots. Asepsis could be approached but never fully achieved.

Among measures to reduce airborne spread of infection, Dr. Lidwell emphasized the importance of doors. The airflow through an open doorway might be 1,000 cubic feet (25.5 cu. m.) per minute—and the doorless openings in some older theatres were a definite risk. Other important factors were reduction of temperature difference between the theatre and the neighbouring rooms, and the maintenance of positive air pressure in the operating-room so that air could leak only outwards around doors and other openings. This required a ventilation system delivering at least 1,000 cubic feet of air per minute, which could both prevent the ingress of airborne bacteria and help to remove those released in the theatre. To avoid the risk of pseudomonas or perhaps *E. coli* infection steam or spinning disc humidifiers could be used in ventilation systems. The incoming air was usually passed through a filter down to 5 microns and introduced at ceiling level, but attempts to direct it around the

operating area had met with only moderate success in reducing the number of airborne bacteria.

Concluding Dr. Lidwell showed that a good ventilation system could enhance working capacity by accurate control of temperature, but studies of comfort at different temperature levels had revealed some individual variation. Anaesthetists preferred to be about 4° F. (2° C.) warmer than surgeons, for instance, while a few of the latter felt too hot unless the temperature was reduced to the low sixties.

An aseptic operating enclosure for use in hip-prosthesis surgery was described by Mr. J. CHARNLEY (Wrightington Hospital, near Wigan, Lancs), who emphasized the need for absolute sterility in this type of operation. The use of a 7-ft. (2.1 m.) square transparent enclosure within a larger theatre had made possible the provision of a downward stream of sterile air at the rate of 300 air changes per hour without high cost or inconvenience. Only the surgeon, two assistants, and one sister worked within the enclosure, their expired air being withdrawn by suction appliances, worn under complete face and head masks, and removed by vacuum tubes down the back. The flow of 5 cubic feet (0.2 cu. m.) per minute under the mask had a markedly refreshing effect and reduced sweating, in addition to removing nose or throat bacteria. The patient's head was outside the enclosure, as were the anaesthetist and the rest of the theatre staff.

The ventilation system was situated immediately above the theatre and opened into the ceiling of the enclosure through an aperture 5 feet (1.5 m.) square. The lights were situated at the corners of this to avoid turbulence in the downward airflow, which was barely noticeable at a velocity of 1½ feet (45.7 cm.) per second. Deflection caused by the presence of the patient was beneficial, since the flow then tended to be away from the operation site towards the surgeon. Similarly there was always an outwards current of air through the instrument hatch and other openings. Other precautions were double gloves, separately sterilized instrument containers for each of the seven stages of the operation, and sterilization of the patient's skin with 2% iodine—after a skin test. This was followed by a varnish spray to fix potentially infected epithelial squames that might separate during operation.

Concluding, Mr. Charnley pointed out the simplicity of the method and the ease with which spectators could observe operations from outside the enclosure. He believed that such enclosures could be used in any room—several being supplied from a single autoclave by people in everyday clothes. This would be cheaper and better than expensive attempts at partial cleanliness, for there was nothing between totally sterile and dirty.

Operating-theatre Design

Mr. WALPOLE LEWIN (Cambridge) spoke on factors in theatre design and gave three reasons for failure to reduce the morbidity of operative infection. These were overconfidence in conventional aseptic ritual; complex procedures involving many people and prolonged exposure; and long waiting-lists. Bed turnover rather than quality had become

the criterion of surgical excellence. The load on theatre staffs was excessive, and there was a danger that the "dirty" cases at the end of one surgeon's list would be too closely followed by the important early cases of another surgeon using the same theatre. It took time to clean a theatre properly, and as Lister had said, "Asepsis in this imperfect world is not to be trusted."

It was the surgeon's duty to maintain theatre discipline and exclude infection. Attention had to be given to many factors, including postponement of operations on patients with colds or other infections, use of prophylactic antibiotics, and the wearing of double gloves and gowns covering back and front for all theatre staff. The patient's clothing and theatre trolley should be clean, and too much clutter of staff and apparatus should be avoided. Special equipment—often necessary nowadays—could perhaps be housed outside the theatre proper in adjacent rooms. Finally, humidity, ventilation, and temperature had all to be controlled, and a refrigeration plant was indispensable.

Mr. Walpole Lewin ended by suggesting that the best type of theatre to build at present might be *space*, in which functional areas could be adjusted to incorporate later developments. The accepted figure of 400 square feet (53 sq. m.) was too small for some operations, and there was a danger that all the work on theatre design since the war might be lost in Ministry standardization, if financial rather than surgical considerations were allowed to predominate.

Speaking as an architect, Mr. J. WEEKS (Bartlett School of Architecture, University of London) warned surgeons to be on their guard against architects' running away with ideas. The year 1963, the year of the Royal College of Surgeons' symposium on operating theatre design, had seen the peak of complexity, with every whim indulged, but since then two developments had taken place. Firstly, this complexity of design had become "frozen," and it was now enshrined by the Ministry of Health; and, secondly, accurate measurements had been made of the needs and functions of an operating-theatre. Some of the elaboration going into theatres at present was no longer necessary—though well adapted to intensive use and modern techniques, they were likely to be superseded. Micro-environments might prove more economical than large operating suites with porters hurtling up and down the sterile corridors. Detailed plans were always apt to become "dated"; and simpler suites with anaesthetic and recovery rooms and reserve space between the theatres should provide for future adaptation. If the original building was suitably constructed, later expansion could be on to different floors as well as on the same level. Concluding, Mr. Weeks said that architects and others thought in 1963 that they knew all the answers to operating-theatre design—in 1967 they were quite sure they did not.

The last speaker, Major IAN CAPPERAULD, R.A.M.C., described a portable tent-type operating-theatre with special lighting, ventilation, and electrical equipment, used recently at the Royal Herbert Hospital, Woolwich, while the theatres were temporarily closed for alterations. This theatre, together with many exhibits of modern designs for operating departments, was on show in the Great Hall during the symposium.

Psychotropic Drugs

SIR,—Dr. J. T. Hutchinson's suggestion (2 December, p. 555) of using the suicide rate as a guide to the value or otherwise of antidepressant medication seems reasonable enough. However, the figures I have available do not appear to be encouraging. Assuming that the great majority of suicides are caused by depressive states, one would expect a significant drop in the overall rate for England and Wales. But the figure per 100,000 has been fairly constant¹ during the years 1954 to 1964 at 11 to 12—lowest 11.3 in 1960, highest 12.15 in 1963. Of course it may be that some deleterious factor other than depression has been increasing over the years and counteracting the preventive influences of antidepressant drugs. Or has the severity of depressive states become more intense? Or has the incidence of depression increased? I doubt whether there are reliable statistics to answer these questions. Practical psychiatrists are too busy to grade the severity of depressions accurately enough for research purposes; and not so long ago conditions which are now classified as "masked depression" were given all sorts of other labels.—I am, etc.,

Weybridge,
Surrey.

SIR,—I could not agree more with your correspondent Dr. J. T. Hutchinson when he states in the *B.M.J.*: "It is time that clinicians ceased to be afraid of the dangers of these drugs" (2 December, p. 555). I am sure I speak for hundreds of general practitioners when I affirm that the use of antidepressant drugs (and this certainly includes monoamine oxidase inhibitors) has revolutionized the treatment of depressive illness in family practice.

My partner and I have about 150 patients suffering from various forms of depressive illness in our practice, and half of these attend intermittently for further supplies of antidepressant drugs. They are not asked to do so, but have found from their own experience that the various manifestations of depressive illness are helped by these drugs in a way no other treatment can equal. We have not had a single suicide in the past six years.

There is no doubt whatever that the use of these drugs has greatly added to the satisfaction that the family doctor can get from the management of a wide variety of illnesses that in the past were a source of continuing frustration and anxiety to him. In this context, as a family doctor long interested in psychiatric illness, I feel that the concept by Sargant and others of the wide anxiety-depression spectrum of illness¹ is one of great

interest to general practitioners and one with which they can wholeheartedly agree.

Amitriptyline and nortriptyline are increasingly used, but Parstelin and phenelzine are still very useful in general practice, reactions to them being very rare; and there remains a definite place for the use of a short-term liquid amphetamine preparation for "post-influenzal debility" and the like.—I am, etc.,

SIR,—Dr. J. T. Hutchinson in his concern for the patient needs no support (2 December, p. 555). That he has seen only one death due to drugs in eight years may well depend on what drugs he has tried and in what dosage and combination; two of my patients on a pre-marketing drug trial fared badly: I abandoned this trial and the drug was later withdrawn.

Linking the suicide rate with the efficacy

of drugs is reasonable enough, but one must take account of the management of the patient, which includes the availability of lethal drugs and of clinical assessment, which needs to be reviewed repeatedly for each patient. It is not an overstatement that every depressed patient presents a suicidal risk which one might avoid by admission and full-time observation, but in general a calculated risk has to be taken during the whole course of the illness, particularly when initiative returns.

My own general approach is to separate patients suffering from depressive symptoms—unhappiness, guilt, unworthiness, and hopelessness—and to administer as a first choice convulsive therapy, which is still the most effective and the quickest mode of treatment. I use drugs first for those patients whose "depressive" state needs to be diagnosed and is not self-evident—for instance, preoccupation with spectacles and dentures, fatigability, impaired interests, various chronic somatic symptoms, and so on. These patients hardly ever constitute a suicidal risk, so that the manipulation of drugs until a suitable dosage or combination is found is valid and safe; if this is not achieved convulsant therapy is often effective. Of course by this time the natural history of the illness may also be a factor in improvement.—I am, etc.,

Clomiphene for Ovulation

SIR,—The letter from Dr. P. M. F. Bishop (9 December, p. 617) highlights the dilemma about the proper way to use clomiphene. On the one hand, there is much to be said for Dr. Bishop's view that as the drug appears harmless and as its sole purpose is to stimulate ovulation it should be freely used without elaborate scientific controls. Not many would agree with his implication that the main purpose of the steroid chemists is "to get on with their research work," but the central point is well taken. On the other hand, the induction of ovulation and subsequent fertilization is not a casual process or a frequent demand on the Health Service and it is not unduly fussy to treat the matter with some circumspection.

There are three good reasons for supporting the view taken in your leading article (25 November, p. 434) that accurate hormone assays should be used in connexion with clomiphene administration. The first is in selecting suitable women for the treatment; particularly in identifying those amenorrhoeic subjects with sufficient residual ovarian activity to respond to the treatment, or the women with regular but persistently anovular cycles. Dr. Bishop argues well for vaginal cytology as a compromise between no controls and proper hormone assays, particularly as he has himself done much to popularize these services, but few would deny that they are inferior to hormone assays, and they are inadequate for categorizing the women sub-

jected to the treatment or determining the nature and timing of their response.

The second reason for the use of hormone assays is that they make it possible to fix the day of ovulation with much more accuracy than by vaginal cytology. Indeed the most advanced laboratory services claim to be able to predict the day of ovulation from the rising oestrogen curve and usually advise about the timing of intercourse. At worst, one has valuable data about the pattern of response, which is likely to repeat itself in subsequent courses. The third reason is that hormone assays give quantitative information about the nature of the response. One can tell whether there was any ovarian response, whether the oestrogen excretion was equal to or much above that of the normal cycle, and whether or not it was followed by ovulation and how adequate the luteal phase was. The incidence of multiple pregnancy and of ovarian cyst formation appears to be related to the nature of the ovarian response, which in its turn is a dose-related phenomenon. Accurate information about the ovarian response enables the physician to regulate dosage in subsequent treatments.

I believe that these reasons are sufficiently compelling to justify some voluntary restriction of the freedom of the individual doctor to give his patient whatever treatment he chooses. It is a besetting fact of medicine in our time that it is passing from the individual to the team and from the man to the

institution. As laboratories cannot be brought to patients, patients must sometimes be brought to laboratories. On balance this seems to be a situation where this applies.—I am, etc.,

University of Aberdeen,
Aberdeen.

A. KLOPPER

Using Computers

SIR,—The paper by Mr. S. P. Watts and Dr. E. D. Acheson (25 November, p. 476) calls for two comments. Their study is not essentially a computer method in the accepted sense of the term. It has been done manually. It could certainly be done with business machines. Of course, it is easier with a computer. Hospital activity analysis can provide "treatments" or "persons." It is a matter of input organization (an identity-fix in particular) and programming. There is no "error" between one and the other. They are different things. For year-to-year comparisons "treatments" may be a sufficient indicator. For true morbidity measurements "persons" are inadequate, since they form only the hospital tip of the iceberg.

But, as in all statistics, it depends on what you want to use the rates for. If it is for hospital management—for example, the efficient use of resources—then the "spell" is the right unit. If for disease management—for example, for diagnosis symptom matrices—then the individual "person" record updated with the whole medical history (inside or outside the hospital)—that is, a full-blooded community health record system—is needed.

Hospital activity analysis is intended to lead into this,¹ and some experiments are already being made to extend hospital activity analysis in this direction. In the long run the unified record will pay bigger dividends than record linkage.—I am, etc.,

Animal Reservoirs of Salmonellae

SIR,—I read with interest Dr. L. T. Newman's letter (4 November, p. 296) on the dangers of salmonella infections from pet tortoises and Dr. W. H. Parry's (25 November, p. 486) on the similar dangers from a pet terrapin. I am glad they have stressed the very real risks of animal reservoirs of intestinal infection which so often go unrecognized. Salmonella infections are far from rare¹ and thousands of new cases occur each year in Britain. In 1965 there were 832 cases of paratyphoid fever alone in England and Wales. The paratyphoid fevers may not always cause gastrointestinal symptoms and the carrier state is common and difficult to eradicate.² In addition to the typhoid and paratyphoid fevers salmonella infections may be far from minor illnesses,³ and a single outbreak in Sweden of *Salmonella typhimurium* was reported which caused 7,717 cases with 90 deaths.⁴

Certain preserved foods are universally recognized as potential sources of salmonella infections. It is not so well known that

nearly every animal in the world, both wild and tame, may carry salmonellae in its gastrointestinal tract, including dogs, foxes, horses, cattle, swine, sheep, goats, hedgehogs, pigeons, and even the ticks, lice, and fleas that feed on infected swine and other animals.⁵ Even the lion is not exempt,⁶ though it could hardly be classified as a pet except perhaps in Ethiopia.

Pet tortoises are a real hazard, but reported infections in iguanas, snakes, and lizards⁷ are more academic than real. As the festive season approaches, however, it is a salutary thought to remember that domestic poultry constitutes the largest single reservoir in nature and that turkeys are especially affected. Some 41% of turkeys in California were found infected with salmonellae.⁸ The canary may be affected⁹ and the dog is a frequent host. In 100 dogs examined in the U.S.A. 18 were found to have salmonella infections, most of which were pathogenic for man. In Norway an infected dog was found to be responsible for six cases of paratyphoid in human beings.¹⁰ In Florida greyhounds were routinely tested, and between 32% and 55% of all dogs were found to be carriers of salmonellae.¹¹ Dogs, after swine, were found to be the most important asymptomatic carriers and 40% of cases were due to *S. typhimurium*. Dogs and cats have been found to be responsible for *S. choleraesuis* transmission to children,¹² and 13.2% of healthy dogs in the U.S.A. were found infected with salmonellae and over 1% of cats in England.⁷

Obviously many salmonellae in animals are non-pathogenic for man. A number may be, however, and the possibility of an enteritis being spread by a pet should always be borne in mind, especially in young children with an undiagnosed gastroenteric infection.—I am, etc.,

Improving the Psychiatric Services

SIR,—There is a great deal of evidence indicating that readmission rates for discharged ex-psychiatric hospital patients are less among those provided with reasonably effective psychiatric aftercare.¹⁻⁴

Psychiatric patients can cause great disturbance and trial to others when left at home. Visiting can provide early warning that modification of treatment or persuasion to take tablets has become urgent. Thus in quite a number of these patients a relapse

can be averted. I find that a large number stop taking their tablets, and that a recurrence of symptoms within a few weeks follows. When there is no follow-up the patient will often not visit a doctor. Relatives are diffident about complaining. Maintenance of morale in many depressive patients does also appear to depend to some extent upon follow-up, and there being somebody, perhaps outside the immediate circle of the patient, giving disinterested help and caring. Dudgeon⁵ noted that as many as 23% of 471 patients seen a year after leaving mental hospitals had had no contact with a doctor or any other type of trained mental health worker since discharge.

The consequences of a significant number of schizophrenic patients stopping tablets have been outlined.¹⁻⁴ I have seen not one but a number of patients descend to further suicidal attempts following sudden cessation of antidepressant drugs. If in addition to cessation of drugs they are discharged from psychiatric outpatient clinics then it would seem vital that they be visited by someone from the mental welfare services.

In 1952 Dr. Arthur Pool initiated a six-week-in, six-week-out geriatric service in Oldham, with an associated day hospital. This alleviated the situation and did relieve many people with elderly relations as well as the patients. Spread of this system would appear to be well worth while and within the scope of numbers of existing institutions and staffs. As part of this scheme all relatives undertook to have their patients home at the end of the period so that everyone could benefit. They were made to realize that the scheme could only work widely if this was kept to. There was free use of admissions of the elderly, so that the relations who were doing their bit by keeping them at home could get off for needed holidays. Keystones in this system were the co-operation of geriatricians and of the ambulance department, which we had.—I am, etc.,

Intussusception Due to Hamartoma

SIR,—A rare lesion of the base of the appendix may have initiated acute appendicitis and subsequent intussusception of the caecum, and is reported below:

A diagnosis of acute appendicitis was made on a 10-year-old boy, and at operation an acutely inflamed appendix was removed and the stump buried with a purse-string suture. Apart from oedema and local fibrinous exudate over the ileocaecal region no other abnormality was noted. The histology of the excised appendix showed acute appendicitis. After operation he made rapid progress, but on the sixth day complained of colicky abdominal pain. There was some tenderness elicited over the site of the scar, but the symptoms rapidly subsided and he was discharged home on the ninth day.

Two weeks later the patient complained of several brief attacks of colicky central abdominal pain, and during one of these his general prac-

itioner palpated an epigastric mass. On admission the child appeared well. He was afebrile and the pulse rate was normal. The abdomen was soft and the presence of a mass was not confirmed. Rectal examination was negative, and plain x-rays of the abdomen showed no evidence of fluid levels or dilated loops of bowel. He was therefore observed for 24 hours, after which time he complained of further abdominal pain. Examination during a spasm of pain confirmed the presence of a tender sausage-shaped mass in the epigastrium. A diagnosis of intussusception was made, and an immediate barium enema performed, which confirmed this. The apex lay in the epigastrium. This was readily reduced by the pressure from the enema, and filling was obtained to the caecum. No barium entered the terminal ileum, and a filling defect was demonstrated in the ileocaecal region (Fig. 1). It was not possible to be certain, therefore, that reduction had been complete.

FIG. 1.—Radiograph showing the caecum (C) with a persistent filling defect (D) at its base.

Laparotomy was undertaken through a right paramedian incision under general anaesthesia. It was found that the intussusception had been completely reduced, but there was a soft mass palpable through the wall of the caecum in the region of the healed appendix stump. This felt like a tumour of approximately 3 cm. in diameter and accounted for the filling defect seen in the radiograph and under the image intensifier. It was considered unwise to open the caecum, so a right hemicolectomy was performed and an end-to-side anastomosis made between the terminal

FIG. 2.—Diagram to show the position of the submucosal hamartoma (H) in the region of the appendix stump. I=terminal ileum. C=caecum.

ileum and colon. The abdomen was closed and the patient made an uninterrupted recovery. He was discharged home 12 days later, and has since remained well with a single bowel action daily.

The operation specimen was opened to reveal a small intramural tumour at the site of the appendix stump (Fig. 2). This was of soft rubbery consistence and measured 3 cm. by 2 cm. Histologically it was shown to be a benign hamartoma showing proliferation of vascular and nervous elements.

It is possible that in this patient obstruction of the appendiceal lumen by the hamartoma preceded the primary infection. The apex of an intussusception may be formed by the base of the appendix where this is unduly broad, or concretions, worms, a mucocele, or a polyp protrude from the lumen.

Although it is standard practice to bury the stump the chances of this acting as the apex of an intussusception are infinitesimal. In this case the hamartoma was missed at the first operation on account of the oedema caused by the inflammatory condition, and it is suggested that burying the stump had the effect of pushing the tumour towards the lumen of the caecum, which was unduly mobile. This created the apex of the intussusception. This complication is so rare that it should not prevent the surgeon burying the appendix stump routinely.

I wish to thank Mr. D. B. Craig for permission to publish this case, Dr. J. M. Burbury for the radiograph.

Prevention of Rh-haemolytic Disease

SIR,—Professor C. A. Clarke's answer (25 November, p. 484) necessitates further comment. He states that the number of cases in the various trials has increased considerably since his lecture. I have received the up-to-date figures, and although the total number of cases in the United States group has increased—for example, the controls from 347 to 503—surprisingly the number of immunizations has decreased from 40 to 36. The Liverpool and Edinburgh figures have not changed, but the German figures have actually decreased from 152 to 117, yet show one more immunization in the controls. Difficulties of this sort had made me confine my questions to the Liverpool series.

Regarding second pregnancies, as the initiative lies with the patient to notify when pregnant again one can guess that the response has been far from complete, and it could be that abortions would less likely be reported. An individual follow-up would give more true assessment.

Professor Clarke agrees that enhancement of immunization by IgM has not been satisfactorily explained and that it is not yet known whether suppression of D-immunization is specific. The mechanism of suppression with the use of gammaglobulin is equally ill-understood and much of the current literature on immunology¹ emphasizes this. As for the antigenicity of gammaglobulin, it may not be valid to compare the use of anti-D gammaglobulin in parturient normal women with gammaglobulin given to patients during

pregnancy, when there is a raised threshold to primary immunization,² or with gammaglobulin given to patients suffering from agammaglobulinaemia, who have a subnormal antibody response.

Gm antigens are transfused when whole blood or plasma is given and can stimulate anti-Gm, but when the gammaglobulin is fractionated, given intramuscularly, and without the competitive red cell antigens, its antigenicity may well be enhanced.³ Frequency of stimulation is probably important, and the incidence of anti-Gm may be greater if gammaglobulin is given to patients who have been previously transfused. Six per cent. of Professor Clarke's treated cases have developed anti-Gm antibodies, which warrants consideration of possible clinical reactions due to these in any further transfusion of these patients, and warrants also consideration of their implication in any further pregnancies and in possible long-term effects. The hypothetical causal relationship between anti-Gm and rheumatoid arthritis has been postulated by Fudenberg and Martensson,⁴ and in fact was mentioned by Professor Clarke himself,⁵ and although there is probably not a simple relationship the role of anti-Gm in rheumatoid arthritis and other immunological disorders is still much under discussion.⁶ Anti-Gm antibodies often display iso-specificity and can occur in the 7S globulin. One assumes that such antibodies could cross the placenta and therefore may have an adverse effect on the foetus. Indeed, the possibility that juvenile rheumatoid arthritis might have some such materno-foetal immunological relationship has also been raised by Fudenberg.⁴

Finally, differing Gm factors in different ethnic groups could also have some relevance when bleeding donors as a source of anti-D gammaglobulin. In view of these and other reservations I think there are "several" most important points requiring research, and that the challenge is

"How covert matters may be best disclosed,
And open perils surest answered."

Intrauterine Transfusion in Rh-isoimmunization

SIR,—The paper by Professor D. V. I. Fairweather and others on intrauterine transfusion in Rh-isoimmunization (28 October, p. 189) calls for some comment. They state that the prolonged anaemia often seen in these babies is due to the depression of bone marrow consequent on the intrauterine transfusion.

However, our personal experience suggests that this might not be the only reason. We have seen three cases of prolonged anaemia occurring in babies who had had intrauterine transfusion, who at 2 months of age had a low reticulocyte count in the peripheral blood, while the bone marrow showed clear signs of erythroid hyperplasia. Coombs test in one

of these cases was strongly positive on the bone marrow, though only very weakly positive on the peripheral blood. The anti-D antibody titre was 1/1,024. Examination of this infant's blood showed that virtually only Rh-negative cells (that is, like those given by transfusion) were present.

This observation supports the hypothesis that the late anaemia seen in very severe Rh disease is due to the persistence of antibodies in the blood. This phenomenon has become apparently more common recently, since, because intrauterine transfusion is now performed, these infants do not require large exchange transfusion at birth, and also there is an increasing survival of severe cases.—We are, etc.,

G. MASERA.
A. MARINI.

Gastritis, Aspirin, and Alcohol

SIR,—We were interested in Dr. C. E. Astley's letter (25 November, p. 484), and particularly his last paragraph in which he suggests that regular beer drinking over a number of years eventually leads to duodenal ulcer. Our practices are in Middlesbrough and Redcar, the same area as Dr. Astley's consulting practice. Recently, together with Dr. G. R. Freedman, of Newcastle, and Dr. I. C. Fuller, of Sedgefield, we made a survey of cases of duodenal ulcer in our practices. In this survey various factors in our cases of radiologically proved duodenal ulcer were compared with ulcer-free controls selected by a statistically sound method using random numbers. The figures quoted below are from the Middlesbrough and Redcar practices only. Superficially, at least, our figures do not support Dr. Astley's contention.

In Middlesbrough there were 42 male cases of proved duodenal ulcer, of which 20 (47.5%) were beer drinkers. The average weekly consumption was 6.3 pints (3.6 l.) of bitter beer. Controls numbered 24, including 17 beer drinkers (71%), average consumption 6.5 pints (3.7 l.). In Redcar out of 34 proved cases 19 were beer drinkers (56%), average consumption 11.1 pints (6.4 l.), whereas 25 controls included 16 drinkers (64%), average consumption 11.0 pints (6.3 l.). The difference in the beer consumption between the two towns probably reflects different social patterns in the two practices, the Redcar practice having a higher percentage of steel workers, who have a long-standing tradition of beer drinking.

It is possible that some patients with duodenal ulcer have stopped drinking because of previous advice or adverse effects of alcohol upon their symptoms. In the combined practices, 17 proved cases admitted that alcohol aggravated their symptoms, but 10 were still drinking beer. If the 7 who were apparently deterred are added to the beer drinkers, then the percentage of beer drinkers in controls is still higher than in the cases of duodenal ulcer. The pattern of drinking among ulcer cases and controls in each practice is remarkably consistent, and suggests that if advice to stop drinking has been followed it has been on the all or none principle. This advice too would probably have included smoking in its restrictions. There were, however, in the combined practices

58% of smokers in the proved cases, compared with 45% in the controls.

This illustrates the difficulties which arise when environmental causes are attributed to duodenal ulcer, and more work must be done on a prospective basis before Dr. Astley's contention can be accepted.

With Dr. Astley's stricture on aspirin, particularly Alka-seltzer, we are in complete agreement.—We are, etc.,

Middlesbrough,
Yorks.

G. K. H. HODGKIN.
J. WHEWELL.

Alcoholic Content

SIR,—In 1961 I made a suggestion that it was time that the alcoholic content of beverages was properly described on the bottles in terms of approximate percentage by volume. Labels which refer to degrees of proof spirit convey precisely nothing to most people.

It is not only spirits, usually about 40% by volume of alcohol, which should be properly described: various beers and stouts can vary from 3% up to, in one case, 11%. Sherry, port, madeira, and marsala may contain 18%, and wines from 9 to 15%. These must serve as examples of the problem.

In view of new legislation, and a new sense of awareness of road dangers, surely the time has come when drivers, cyclists, and pedestrians are entitled to know just what they are imbibing, and have we not a duty to help the populace to educate itself by learning how and what to drink, and how not to?

To avoid over-elaboration in a letter, may I refer anyone interested to the summer and autumn editions of *Health Horizon* 1961, which go more fully both into the matter of per cent. labelling and alcohol and the driver? What seemed important then seems to be highly relevant today.—I am, etc.,

Broadbridge Heath,
Sussex.

GUY BOUSFIELD.

Endocarditis and the Mitral Valve

SIR,—In our paper "Prolapse of the Posterior Leaflet of the Mitral Valve: A Clinical, Familial, and Cineangiographic Study" (8 July, p. 71) we suggested that bacterial endocarditis was unlikely to be a complication of this lesion although other authors had suggested that these patients should receive penicillin prophylaxis for dental work. We now wish to report a case of *Streptococcus viridans* endocarditis in one of our patients who had previously been found to have prolapse of the posterior leaflet of the mitral valve.

The patient, a male aged 35 years, was investigated by means of left ventricular cineangiography in May 1967, after a systolic click and late systolic murmur had been found on routine examination. Investigation revealed the typical abnormality of prolapse of the posterior leaflet of the mitral valve into the left atrium with late mitral incompetence. The patient was seen again in October, with a four-week history of malaise and fever for which he had received several short courses of penicillin. (Shortly before the onset of this illness he had been bitten by a dog on the left calf.) On examination he

had a fever, but there was no change in his cardiac auscultatory findings and no other findings to suggest the diagnosis of bacterial endocarditis. E.S.R. was 34 mm. in one hour, white cell count was 8,000. Blood cultures were performed and *Str. viridans* was grown from three cultures. The patient was treated with 8 million units of crystalline penicillin intravenously daily for one month and made an uneventful recovery.

We therefore consider that prolapse of the posterior leaflet of the mitral valve may predispose to bacterial endocarditis and that patients with this lesion should receive prophylactic antibiotics for dental work and other conditions which may lead to bacteraemia.—We are, etc.,

Jaundice in Pregnancy

SIR,—I was interested to read your leading article on jaundice in pregnancy (2 December, p. 499), with particular reference to recurrent intrahepatic cholestatic jaundice of pregnancy. Perhaps it should be emphasized more strongly that this is a benign condition, and the prognosis for mother and child are excellent. No special treatment is needed in the antenatal period, such as induction of labour or caesarean section, on account of the jaundice alone. There is an increased tendency for premature delivery in the 38th week, and some authors have noticed a tendency for the prothrombin level to fall and lead to postpartum haemorrhage if not promptly dealt with.

'Thorling' in 1955 produced the classical account of the disease, and he and other authors are agreed that the jaundice usually fades first in the puerperium and that the pruritus resolves within about a week or two after this—this point being at variance with your editorial view. Probably generalized pruritus without jaundice occurring in the last few weeks of pregnancy is part of the same syndrome, and Fast and Roulston¹ pointed out that these patients may have elevated serum bilirubin and alkaline phosphatase levels. They also thought that recurrences occur in at least 50% of cases. The condition is probably a great deal more common than realized, and the recent influx of case reports seems to suggest that obstetricians are becoming more aware of it.—I am, etc.,

J. E. A. ONI-ORISAN.

Stobhill General Hospital,

Massive Overdose of Adrenaline

SIR,—Dr. Michael A. Lewis (7 October, p. 38) speculates on the reasons for the prolonged period of hypotension and tachycardia displayed by his patient without reaching any firm conclusions. Is he able to say what volumes of fluid were administered to this

healthy young woman, and over what periods?

Prolonged hypotension and tachycardia, often accompanied by signs of inadequate cerebral oxygenation, are quite frequently due to overhydration by intravenous therapy. When given orally, excess fluids are rejected by the onset of nausea or active vomiting, but this defence mechanism cannot operate when fluids are administered intravenously. The protocol of Dr. Lewis's patient suggests that considerable volumes of fluid were injected, for he speaks of a large catheter inserted into the saphenous vein and the use of a pressure-pump. It is sometimes forgotten that infused fluids (water) leave the intravascular compartment as rapidly as possible, taking with them a measure of diffusible molecules. The presence of an increased bulk of extravascular fluid in turn retards and even interferes with oxygen and carbon-dioxide molecular diffusion between blood plasma and protoplasm. Where extracellular fluid volume is increased, the intercapillary distance is also increased, and if this exceeds the critical distance discussed by Scharrer¹ cellular ischaemia may progress to a point of irreversibility. The target areas for such a development will depend upon the circumstances, and where intense peripheral vasoconstriction has been produced these target areas are more likely to be myocardium, brain, and lung, where survival dictates that perfusion should be maintained as long as possible.

To me there is one other point of great interest in this report. One has seen so many patients unharmed by prolonged and sometimes profound hypotension that, as I have suggested elsewhere,² we need to realize that blood pressure does not really indicate the extent of the circulation to peripheral tissues. The gross hypertension which operated here and the peripheral vasoconstriction to my mind underlines this generalization, and highlights a need to reappraise our concepts of the practical value of blood-pressure measurement in the clinical practice of medicine.—I am, etc.,

Worcester, C.P.,
South Africa.

Homonymous Hemianopia after Oral Contraceptives

SIR,—Permanent homonymous hemianopia has been recognized for many years as a rare aftermath of a migrainous paroxysm.¹

I have seen two such cases within a few days of each other. In both patients this incident occurred shortly after commencing the contraceptive-pill regimen, which also had the effect of causing severe recrudescence of migraine dormant for some years. Both patients were otherwise fit women in their forties. One of them discontinued the oral contraceptive of her own accord four months ago, and she has remained free from headaches since. The time that has elapsed since the second patient stopped taking oral contraceptives is too short to warrant any conclusion as yet.

These cases may perhaps betoken a migrainous causation of the otherwise unexplained hemiplegia occurring during contraceptive-pill medication, especially since

these drugs have been shown not to produce any abnormality of the coagulation pattern.²—I am, etc.,

London W.1.

SIMON BEHRMAN.

Abortion and Conscience

SIR,—Dr. P. Darby (2 December, p. 549) puts forward the pregnant woman's "well-being" as a medical consideration for abortion. He appears to have forgotten that the "well-being" clause which was included in an earlier stage of the Medical Termination of Pregnancy Bill was withdrawn by its sponsors and is not in the new Abortion Act. That the W.H.O. includes such a phrase in their definition of mental health does not give it legal validity. Neither does it give it medical sanction, for W.H.O. definitions are notoriously unstable and liable to change, as is evidenced by those on alcoholism and drug addiction.

There is no agreement on a definition of "mental health" in spite of national associations, institutes, and research funds devoted to its cause. At a conference in 1956, sponsored by the World Federation for Mental Health and the International Association of Universities, which lasted for 10 days, the delegates agreed they could not define mental health in a simple, universally acceptable manner. What they were able to do was to say what it was not, and the following are the negative statements they produced:

- (1) It is not characterized by adjustment under all circumstances.
- (2) It is not characterized by freedom from anxiety and tension.
- (3) It is not characterized by freedom from dissatisfaction.
- (4) It is not characterized by conformity or constant happiness.
- (5) It does not imply the absence of personal idiosyncrasies.
- (6) It does not imply a lessening of accomplishment or creativity.
- (7) It does not imply the undermining of authority.
- (8) It is in no way opposed to religious values.

These points should be borne in mind when the pregnant woman's "mental health" is being considered.—I am, etc.,

Edgbaston,
Birmingham 15.

MYRE SIM.

Body Building on Drugs

SIR,—May I comment upon the letter (11 November, p. 353) and your leading article (p. 310) concerning the use of anabolic steroids in sport.

The use of these drugs for increasing bulk and strength in power events has been going on since at least 1963. The practice is widespread in the U.S.A., Australasia, and probably Eastern Europe. It is not yet so common in Britain, but it is on the increase. Several Olympic and Commonwealth Games titles and world records have been won and set up by athletes who have influenced their training with anabolic steroids.

The International Amateur Athletic Federation laws are loosely worded on the

definition of doping. They specifically ban the use of drugs which stimulate muscle and nerve (this by my interpretation includes anabolic steroids) and are against in principle all drug-taking in sport. The penalty is banishment from competition for both athlete and accomplice for an indefinite period.

The British Amateur Athletics Board officially recognized this problem in the autumn of 1966. They issued a statement categorically condemning the use of these drugs to influence training.

The International Olympic Committee decided in the spring of 1967 that all athletes taking part in future Olympic Games should sign a declaration stating that they have not used drugs (specifically mentioning anabolic steroids) for influencing their sporting ability.

The problem of detection is real. Even if it should become possible to detect biochemically whether or not the drug has been used, the testing is likely to be a complicated and expensive procedure. This in itself will tend to limit testing in amateur sport. The only ways I see of limiting their use is by (1) making supply of the drug difficult—that is, by all doctors being aware of the abuse—and (2) by the introduction of body weight gain limits into the sports particularly affected.—I am, etc.,

St. Annes-on-Sea,
Lancashire.

M. T. LUCKING.

Restrictions on Doctor in South Africa

SIR,—The recent banning order served on Dr. R. Hoffenberg has rightly been commented on in your columns (26 August, pp. 512 and 556). On 6 September 1967 I sent a letter of resignation to Dr. Burger, Superintendent of Groote Schuur Hospital, Cape Town. This letter was also submitted to the *South African Medical Journal* for publication. Its journal committee decided that all correspondence on the matter would be delayed pending a decision between a deputation from the University of Cape Town and the Minister of Justice. Attempts to obtain such a meeting lasted several months. When the meeting finally took place a few weeks ago the Minister indicated that he was not willing to make concessions on anything other than minor details. The decision of the journal committee in fact meant that, over a long and crucial period, South African doctors were denied the right to protest in their own organ against the banning of their colleague. Immediately after I heard of the meeting between the deputation and the Minister I cabled the *South African Medical Journal* asking whether they would publish my letter. This was refused.

In my letter to Dr. Burger I stated that the major consideration that prompted my resignation was political and was crystallized finally by the ban on Dr. Hoffenberg. To continue to participate in academic activity, to be stimulated by social and intellectual contact with colleagues, and to publish and to teach when a fellow doctor was precluded from doing so was intolerable. I felt that original and critical thought could not survive in academic life in a politically suppressive atmosphere and that freedom of thought was essential.—I am, etc.,

Lemuel Shattuck Hospital,
Boston,
Massachusetts, U.S.A.

S. SHAPIRO.

Overseas Registration and Seniority Payments

SIR,—I was interested to read the letters of Drs. A. M. Poornan (19 August, p. 500) and G. Murtaza (28 October, p. 239) about the rejection of their claims for seniority allowance by the Ministry of Health. The ruling of the Ministry is incompatible with the spirit and principle with which the Review Body introduced this payment.

In para. 159 of the Report¹ it states that this payment "will recognize the development of experience in the general practitioner, and will provide him with the prospect of maintaining the level of his remuneration at a time when he may wish with advancing age . . . to curtail his responsibilities or reduce his work load."

The present ruling of the Ministry will mean that doctors registered overseas will qualify for the payment late in their lives, and some may even retire before getting any increments. It will also delay the recognition of their experience in general practice (the minimum laid down in the Report for allowance is five years), as they will be in practice for more than that time before their claim is accepted. It will also prevent them from reducing their work load with advancing age, should they wish to do so, without a serious financial loss.

Thus it is evident that the Ministry's ruling is quite contrary to the intentions with which these payments were introduced. May I also point out that nowhere in the Report has the registration body been specifically mentioned to be the General Medical Council. Para. 215(4)(c) of the Report says only the *Medical Register*.

Those of us who qualified and registered overseas should be treated in the same manner as doctors qualified and registered in the Irish Republic, or has the Ministry two sets of rules?—I am, etc.,

Manchester 16.

G. J. DRABU.

Seniority Payments

SIR,—I feel that one must take issue with Dr. S. Stowe (2 December, p. 557), who feels strongly on matters of principle and practice that seniority payments should not be tied to a stipulated amount of postgraduate training.

The principle of linking seniority payments with a small postgraduate training requirement seems to me to be reasonable and enlightened. However, it is really the question of practicability that has caused me to write. I found it difficult to imagine that the letter was from a colleague working in the same conurbation as myself. Are there not week-end rotas in Wolverhampton? Do the doctors still live and work in isolation? Is it not possible to ring up a friend in the vicinity and get him to cover for the odd Saturday morning? Will no locum work in the area? Are there no hospital staff who would undertake to come in at times? The use of any or all of these simple methods would enable Dr. Stowe to get away for postgraduate training, and he is fortunate to be in an area served by the University of Birmingham Medical School and the Midland faculty of the Royal College of General Practitioners. He has on offer a plethora of

week-end courses, together with the possibility of individual attachment in virtually any specialty he cares to study. In Birmingham itself there are excellent postgraduate facilities available at most of the major hospitals, and I would imagine that the same applies in the Wolverhampton area.

The need for postgraduate training is being increasingly recognized, and for many the stipulation linking this with seniority payments is accepted without any apprehension, for it is really rather pleasant to revert to being a student again.—I am, etc.,

Handsworth,
Birmingham 21.

K. G. DICKINSON.

Thirteen-week Certificate

SIR,—A number of my patients who have long-standing chronic illness such as disseminated sclerosis, chronic bronchitis, and ankylosing spondylitis are likely to survive for many years but will be quite unable to resume work. Many are unable to attend the surgery and require a home visit on fixed dates for the purpose of insurance certification.

It is my practice to visit such patients only when a change in their medical condition demands such a visit, and this rarely coincides with the timing of certification. It therefore becomes necessary to make home visits for a purely non-medical administrative procedure.

Would it be possible for one of the following alternative measures to be given consideration?

(1) Arrangements for a medical board to review such cases at yearly or less frequent intervals, thus dispensing with certification by the general practitioner altogether.

(2) That it be required for the general practitioner to certify that he has seen the patient in the interval between the regular 13-week periodic dates, rather than on a fixed day.—I am, etc.,

Oldham,
Lancashire.

G. LLOYD.

"Mediflash"

SIR,—The usefulness of the "Mediflash" was proved recently during the Hither Green train disaster.

Having heard the news on the radio a local doctor drove towards the scene of the accident only to find the traffic completely at a standstill and blocking his way. However, the police recognized his "Mediflash" and he was directed to pull out to the right-hand side of the road and was waved on by the police to the actual disaster area.—I am, etc.,

London S.E.12.

First Fellows of the Royal College of General Practitioners

SIR,—Whatever one may think of the main burden of Dr. B. I. Kohlinsky's letter about the list of new Fellows of the Royal College of General Practitioners (2 December, p. 557) his last statement demands flat repudiation, the more so because it seems to be a view held, erroneously, by many other doctors.

If these doctors had read the documents that really matter instead of the giveaway medical journals, they would have found in the Second Report¹ of Joint Discussions between General Practitioners' Representatives

and the Ministry of Health, paragraph 19: "... the Government propose that the ... recognition of ... experience and special qualifications ... should be furthered by way of additions to the basic practice allowance."

Later in the same document there is a paragraph head "Special Experience and Service to General Practice." It contains the following words: "The profession's representatives made it quite clear that no such proposal appeared in the charter and that they had no mandate to agree."

At no time did the negotiators accept the principle of merit awards. Of this anyone who has read the documents mentioned above or listened to or read the negotiators' statements on the subject can be in no doubt whatsoever.

It should be further noted that the negotiators are elected by and responsible to the G.M.S. Committee only, and through it to all general practitioners. It is notable that of the 71 new Fellows of the R.C.G.P. from the United Kingdom, only one is a member of the G.M.S. Committee and one other has recently been so.

It only remains to make the obvious point that the Royal College of General Practitioners has absolutely no power over the G.M.S.C.—I am, etc.,

Clarendon,
Warwick.

B. D. MORGAN WILLIAMS.

Points from Letters

Nicotinic Acid in Acne

Dr. N. ISLAM (Dacca, E. Pakistan) writes: Acne vulgaris most commonly develops during puberty, a period during which people are very conscious of their appearance. . . . Various treatments have been suggested from time to time. . . . It was a chance finding that nicotinic acid is effective against this condition and I have treated 20 cases. The age range was from 15 to 35 years.

The patients who develop facial flush do better with this treatment. Initially a dose of 100 mg. thrice daily was advised. Then the patient was instructed to go on increasing the dose by 100 mg. daily till a facial or a generalized flush was observed. Subsequently it was advised to continue this "flush dose" for two to three weeks. It was interesting to note that the dose varied from patient to patient and ranged from 100 mg. to 1,000 mg. a day. Duration of treatment varied from 10 to 30 days, depending on the severity of the lesion.

Medical Science—Master or Servant?

Dr. M. S. ROSE (Experimental Haematology Research Unit, St. Mary's Hospital Medical School, London W.2) writes: Scanning the *B.M.J.* today (2 December) I wondered whether Lord Platt was disappointed at apparently evoking no controversy with the publication of his Harveian Oration (25 November, p. 439). Your editorial "Cui Bono?" (p. 433) appeared to assert that Lord Platt's views should concern us because of who he is rather than because of what he says, which was a pretty crazy way of introducing otherwise creditable comment. . . . I wonder whether the departure of so many graduates overseas and the loss of others from general subjects in medicine into ancillary fields is not in part an expression of frustration at not finding a purposeful framework in which to become involved. On graduating the vast majority are on their own. "Ars gratia artis" is fine for Metro-Goldwyn-Mayer but can hardly do credit to such an intrinsic service as medical care of the sick.

Obituary Notices

J. W. LINNELL, M.C., M.D., F.R.C.P.

Dr. J. W. Linnell, a former consulting physician to the Metropolitan Hospital and to the Mildmay Mission Hospital, London, died at his home, the Retreat, at Pavenham, Bedfordshire, on 2 December. He was 89.

John Wycliffe Linnell, a son of the Rev. J. E. Linnell, vicar of Pavenham, was born on 31 October 1878, and was educated at Bedford Modern School and St. John's College, Cambridge. For his clinical studies he went to the London Hospital, graduating M.B., B.Chir. in 1907. After house appointments he carried out research work in tuberculosis at the Hospital for Diseases of the Chest, Ventnor, Isle of Wight, at the Mount Vernon Hospital, Hampstead, and as Gibbons research student at St. George's Hospital, London. He proceeded M.D. in 1913. During the first world war he served with distinction as a regimental officer in Gallipoli, France, and Egypt, attaining the rank of major. He was awarded the Military Cross and was mentioned in dispatches. After demobilization he took the M.R.C.P. in 1921, and was appointed medical registrar at the London Hospital. Subsequently he acted as assistant to Sir James Mackenzie, and later to Sir John Parkinson in the cardiac department of the hospital. He was then appointed physician to the Metropolitan Hospital and to the Mildmay Mission Hospital, continuing on the staff of both hospitals until he reached the statutory retiring age. He also became consulting physician to the endocrine unit of New End Hospital, Hampstead. In 1940 he was elected F.R.C.P.

Dr. Linnell was chiefly interested in cardiac and pulmonary diseases, and especially in disorders of the thyroid gland. His contributions to medical literature mainly concerned these subjects. He was also co-founder of the Thyroid Club. Dr. Linnell never married but lived at Pavenham with his brother and widowed sister, both of whom predeceased him.

C. W.-D. writes: Jack Linnell was a charming personality who will be very much missed by a wide circle of friends and colleagues. He was an admirable raconteur, and it was always a pleasure to meet him both professionally and socially and enjoy his conversation. Apart from contributions to medical literature he wrote a most interesting book entitled *Old Oak*, a story of a forest Northamptonshire village. Not only in London but also in Bedford he carried on consulting practices, both of which could have been more extensive had he wished, and one could always rely on him for a sound opinion. With his kindly disposition the question of fee never seemed a matter of interest in him. During the many years we were colleagues I never heard him say a really unkind word about anybody. His recreation was mainly that of taking long walks—"tramping," as he termed it—in Switzerland and Germany, usually accompanied by his schoolmaster brother. As a result of what he saw in Germany in the 1930s he told me before the second world war that he was quite certain that the Germans were

preparing for war, and I believe he conveyed his views to the authorities concerned. He was an enthusiastic supporter of rugby football, and very seldom missed attending the Oxford and Cambridge match and the internationals at Twickenham. One must be thankful that Jack Linnell was spared to us for so long.

G. M. S. writes: With a wicked twinkle at times in his intensely blue eyes J. W. Linnell belied the austere evangelical rectory atmosphere in which he, his three brothers, and one sister had been reared. Although prepared to mock at any sign of pomposity or self-aggrandizement that crossed his path, he paid the highest tribute to integrity, to loyalty, and to devoted service whatever the cause. Many are the students, the housemen, and the registrars who breathed their thanks for help given at the right moment, for an uncanny insight into their difficulties, and an unaccountable effort to solve them. From the rectory at Pavenham, Bedfordshire, to the aptly named "Retreat" near by, the spirit built up collectively by the Linnell family permeated the neighbourhood and beyond. Visitors from London were encouraged to come for week-ends and to enjoy especially the Sunday teas which were such a feature of the Retreat for so many years. A genius for friendship, kept up by letters all over the world, contributed to the width of knowledge which illuminated discussions whenever a few congenial people met. Jack, as he was known to all his friends, was an uncompromising Christian and an ardent supporter of the Bible Society and its associations, but to his many friends he was the kindly ever-helpful physician who spared no effort to assist in any way. He always maintained that the right attitude was not "to turn the other cheek" but to "fight the good fight with all his might."

B. A. MEYER, M.B., CH.B.

Dr. B. A. Meyer, who was engaged in general practice in the West End of London, died suddenly at his home on 21 November after a long illness. He was 66.

Benjamin Arnold Meyer was born in Cape Town on 25 December 1901, and from his earliest days determined to study medicine. He won a bursary to the University of Cape Town, and from there obtained permission to take his medical course in the United Kingdom. He chose to attend Edinburgh University, and graduated M.B., Ch.B. in 1925, taking the Scottish triple qualification in the same year. After a distinguished undergraduate career he took an additional course in midwifery at the Rotunda Hospital, Dublin. He became assistant to a general practitioner in a country district in Scotland whose firm view it was that they should be able to perform all the surgery in the practice themselves. This delighted Bobby Meyer and stimulated his interest in a branch of medicine which already had a marked attraction for him. After two years he went home

to South Africa, meaning always to return to Great Britain. After five years spent in resident surgical appointments and general practice near Durban he achieved his ambition, first taking a resident post at the Royal Sussex Hospital in Brighton, and then a partnership in general practice in the same town. He subsequently set up practice on his own account in Streatham, and then in central London, keeping alive his interest in surgery with clinical assistantships and for a period a part-time surgical registrarship at the National Temperance Hospital. He revisited South Africa many times to stay with his relations and his many friends there.

Bobby Meyer was a man of great kindness and personal charm. He knew life, and loved it. These qualities, together with his wide medical experience, made him the ideal general practitioner and family physician. He had other gifts besides—a powerful memory, a facility for friendship, and a sense of humour which was characteristically evident to the day of his death. He was a fascinating raconteur, and among other achievements he wrote a play for radio which was performed a few years ago.

The passing of Bobby Meyer is mourned alike by his patients, colleagues, and friends. His devoted wife, his son, and two daughters provided a background of complete happiness and pleasure for him, and we extend our deep sympathy to them.—S. M.-D.

N. J. NICHOLSON, M.B., CH.B.

F.R.C.S.ED., F.I.C.S.

Mr. N. J. Nicholson, emeritus surgeon, County Hospital, Louth, died at his home on 30 October. He was 65.

Neville Jennings Nicholson was born on 13 November 1901, and received his early education at Durham School. He entered the University of Edinburgh, and graduated M.B., Ch.B. in 1927. Keen on rowing and football, he was captain of both boats and rugby football in 1920 at Durham School, later rowing for Edinburgh University as well as being a member of the university rugby team. After holding early resident appointments he took the F.R.C.S.ED. in 1935, and from 1936 to 1938 he was surgeon and deputy superintendent of the Municipal Hospital at Birkenhead. In December 1937 he was appointed surgeon and superintendent of the newly opened County Hospital at Louth. He was active in building up the new hospital, which played an important part in the second world war in providing a treatment centre for large numbers of Service men. On his retirement in 1966 he was given the title of emeritus surgeon. He was also surgeon to Alford, Skegness, and Louth district hospitals.

Mr. Nicholson was a former chairman of the Lincoln Medical Society, a member of the British Medical Association, and chairman of the Grimsby Division in 1957-8. He had been a member of Louth Borough Council for eleven years, and was mayor of Louth in 1963.

He married in 1939, and had a son and four daughters.

Blind People in Scotland

Last year the number of registered blind people in Scotland fell by 46 to 10,341, according to the Scottish Home and Health Department. Of this total 52% were aged 70 or over.

New registrations during 1966 totalled 1,271. Of these, 66% were over 70, while 20 persons were children under 16, six being under 5 and one under 2.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending 25 November (No. 47) and corresponding week 1966.

Figures of cases are for the countries shown and for Greater London. Figures of deaths and births are for the whole of England and Wales (London included), Greater London, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

PARLIAMENT

Qualified Support for Health Services Bill

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The second reading of the Health Services and Public Health Bill on 7 December produced no significant opposition, but much questioning of the intentions of the Minister of Health in exercising the powers the Bill gives him. This will be carried further during the committee stage after the Christmas recess, and will examine more closely several sections of the Bill which received only preliminary attention. These include, for example, executive council powers to supply goods to doctors and others, and the health and welfare work of local authorities; also policy towards pay-beds and private practice. (See *B.M.J.*, 2 December, p. 562.)

This Bill is concerned mostly with subsidiary changes in the administrative structure of the Health Service. Major changes must await the full examination which the Minister has begun, and on which he is to publish in due course some tentative proposals.

No Reduction in Pay-beds

Mr. KENNETH ROBINSON began his exposition of the Bill by explaining that the purpose of Clauses 1 and 2, which had aroused some misunderstanding, was not to reduce or abolish the number of pay-beds. The main changes, which followed the review of pay-beds he announced a month ago, were to introduce a degree of flexibility in the use of accommodation by private patients, and to enable charges to be determined on a national basis for different classes of hospitals, instead of by reference to the cost at the particular hospital. The Bill also enabled him to dispense with regulations in determining charges for private outpatients, and for amenity beds. Apart from this the clauses merely repeated provisions which had been in force nearly 20 years.

To those Labour M.P.s who disliked private practice on principle he gave an assurance that he had no intention of using these powers to extend the area of private practice in hospitals. He equally assured the medical profession that the clauses did not enable the Minister to abolish their right to treat private patients, nor was this his intention. But the powers would, he believed, make possible a more rational use of all hospital beds, public and private.

University Hospitals

The most significant administrative change, he thought, was the power taken in Clause 5 for a new designation of hospitals—"university hospitals."

The Government had approved the creation of medical centres at the Universities of Nottingham and Southampton. At both places facilities for clinical training would be needed in hospitals which did not now provide them. The creation of new medical schools provided an opportunity to link more closely the regional boards with the new centres of medical education. The universities, however, should be assured of a voice in

the planning and administration of such hospitals, and that was not provided for in the normal constitution of management committees.

Clause 5 required him to consult the university concerned before designating a university hospital. Such a hospital would be managed by a management committee appointed by the regional board, but with a special constitution which would ensure that the university had adequate representation.

The clause was not confined to hospitals associated with new medical schools. It would also give latitude in devising suitable administrative arrangements where, to accommodate larger numbers of students, a second main hospital was to share the responsibility with the existing teaching hospital. It was not the present intention, he stated, to use the clause to effect sweeping changes in the administration of teaching hospitals already controlled by boards of governors.

Ophthalmic Services

Dealing with the provisions affecting executive council services, the Minister said the hospital ophthalmic clinics had not developed along the lines envisaged in 1946. Instead, the hospital eye service had in the main dealt with the more specialized requirements, while the supplementary ophthalmic services, far from becoming redundant in any area, had been the normal means under the Health Service of meeting the ordinary optical needs of the population. The Bill recognized this by making the services permanent and renaming them "general ophthalmic services." The membership of the executive councils was being altered to reflect the three groups of practitioners involved—ophthalmic medical practitioners, ophthalmic opticians, and dispensing opticians.

Practice at Health Centres

Originally only National Health services were to be provided in health centres, but since 1949 doctors had been able to practise privately there, and this had made some health centres more attractive to doctors and patients alike. There would be localities where similar extensions to the other services provided in health centres could be beneficial to patients attending them, and the Bill made it possible for dentists, opticians, and pharmacists to engage in private practice at health centres to such an extent and subject to such conditions as the Minister might determine.

He also had proposals to improve the arrangements which could be made for the postgraduate education of family doctors, dentists, pharmaceutical chemists, and opticians concerned with providing family practitioner services. Clause 25 accordingly conferred somewhat wider powers than those in section 48 of the 1946 Act. It would not only apply to those who were actually engaged in family practitioner services but also to those who were thinking of doing so, and would enable a wider range of instruction to be given.

Inadequate Consultation

Mr. MAURICE MACMILLAN, the Conservative spokesman on health legislation, assured the Minister that there was no intention on their part to delay or obstruct the passage of the Bill, but he pressed for time for full consultations before the committee stage. Some of the bodies concerned had informed him that there had been no consultation prior to the publication of the Bill, and were unaware only a month or two ago of any possibility of legislation affecting them being brought forward.

Mr. ROBINSON asked him to be more specific, because there had been extensive consultations over "vast areas" of the Bill. If there had been a particular failure to consult he would like to know about it, and would express his regret if it was so.

Mr. MACMILLAN replied that both the doctors and the pharmacists had publicly stated that they had not been fully consulted. The fact that there had been such widespread misgivings over pay-beds and the clauses dealing with the manufacture and supply of drugs was an indication that consultation was not sufficient.

He asked for an assurance, on rising costs, that the Minister would not economize simply where economies were easy. There was a danger that economies were effected at the expense of freedom of choice of treatment and might militate against the use of prophylactic drugs.

Private Practice

The clauses on pay-beds would require time for consultation. The Opposition were glad of the Minister's assurances, and accepted that the Bill was neutral in its approach to private practice. But he asked what effect this greater flexibility would have on waiting-lists, and how adjustments would be made now that beds were not to be designated. It was important that there should be no question of private patients jumping the queue, and equally that there should be no question of their being prejudiced, or of the Bill being so administered as to lessen the freedom of choice of the consultant and militate against part-time consultants. They would be asking the same sort of questions about charges. It was obviously sensible that charges should be regularized according to the nature of the care provided. It was equally obvious that the Minister could price the private patient out of the market, although, Mr. Macmillan added, he was not saying that he wished to do so.

He indicated that while the Opposition welcomed Clause 5 they would be happier if it was so drafted as to indicate that it was experimental and subject to review, and that they would like some assurance about the future of teaching hospitals and about the use of funds to initiate work or research not being undertaken by regional boards.

Occupational Health Service

Mr. K. LOMAS (Huddersfield, West, Lab.), having deplored the omission of provision for an occupational health service, went on to voice what he called the deep-rooted suspicion

of pay-beds, not solely confined to Labour Party supporters, and to demand a still further reduction in their number, the adoption of a salaried service, and the abolition of the part-time consultant.

Dr. M. S. MILLER (Glasgow, Kelvingrove, Lab.), a practising doctor until recently, regretted that 20 years after the inauguration of the Health Service the family doctor system was still based on the concepts of the 1920s or even earlier. He was worried that the nation was not making proper use of its 23,000 general practitioners. The family doctor, working from a health centre, should be the head of a health team in which he carried out the highly skilled work and the clerical and less highly skilled routine was carried out by ancillary staff.

Dr. M. P. WINSTANLEY (Cheadle), who speaks for the Liberal Party in these debates, fully endorsed the idea of the general practitioner as the leader of a welfare team. If the Minister put more emphasis on the clauses dealing with health centres and facilities he would find the doctors would stay in Britain. Postgraduate education was another means of keeping doctors here.

Dr. J. DUNWOODY (Falmouth and Camborne, Lab.) said he had been opposed to private practice since he was a medical student; it was morally indefensible and medically inefficient. Unoccupied private beds in hospitals should be used for Health Service patients. He welcomed the fact that more attention was to be paid to postgraduate medical education. There was a great need for this. The average doctor would during his working life see a complete transformation in the medical scene, and the need for regular refresher courses was increasing.

Lack of Confidence

Mr. P. GRIEVE (Solihull, Con.) asserted that there was a great lack of confidence

between the medical profession and the Minister. It was the use that the Minister would make of the new flexibility that worried the doctors. He quoted the reported remarks of Mr. Robinson's Bloch Lecture at Glasgow University the previous day, and commented that if there was an impression of antagonism between the Minister and representatives of the profession the fault was not all on one side, but lay very much with him.

He went on to argue that the new flexibility must be properly used, and that the demand for private practice was increasing, not decreasing.

Dr. DAVID KERR (Wandsworth, Central, Lab.) interjected, "Shame," and explained: "I do not deny the patient the right to private treatment. What I cry shame about is that there is thought to be a need for an extension of private practice, and that there should be an attempt to justify it as the kind of practice that ought to be followed. I think it should diminish, as the kind of practice that ought not to be followed."

Mr. GRIEVE replied that people were entitled to go to their own doctor and pay him if they wished. This was recognized in the Health Service Act. The complaint was that the Minister had been whittling it away.

Mr. ROBINSON here intervened, to state that over 18 months ago he discussed with the leaders of hospital doctors a package deal in connexion with pay-beds. There were features they liked, and features they did not like. They acquiesced in the total package, and part of it was that he would review the total numbers of pay-beds to adjust the pressure on them to something like the pressure on non-pay beds.

"Another part of the package," he continued, "was to do what no Conservative Minister was ever willing to do. I lifted completely the ceiling on fees which private consultants could earn from private patients in Health Service hospitals. You might take

the whole package together, instead of one aspect of which you complain."

Mr. GRIEVE said the aspect he was taking concerned the availability of something for which there was a demand. The figures of B.U.P.A. for insurance for private medicine spoke for themselves. At Glasgow the Minister sought to draw a contrast between representatives of the profession whom he criticized and the younger doctors. Was it the middle-aged or the elderly who had been emigrating? The answer to the Minister's completely false point lay in the emigration of thousands of young doctors who were not prepared to work in the Service under the conditions imposed by the Minister.

For the Record

In a short survey of progress in the Health Service which the Minister gave as a prelude to the debate he claimed that the new deal for general practice, in spite of setbacks resulting from the prices and incomes policy, had been fully in operation since last April, and he believed they had turned the corner.

There had been a remarkable upsurge of interest in health centres; 23 had been opened in the past three years, 38 were being built, 50 more had been approved, and 71 were being actively planned.

There was an intake of 2,431 students in the medical schools this autumn term. By 1970 the total would have risen to an estimated 2,800.

This year no less than £100 million would be spent on new hospital building in Great Britain. During the Government's three complete years in office the total would be £262 million.

In 1966 the number of hospital inpatients was nearly 4,900,000, a rise of almost 1,500,000 over 1953, the earliest year for which there were reliable figures.

MEDICAL NEWS

Emeritus Professors

The title of Professor Emeritus in respect to their posts has been conferred on the following:

Professor C. P. BEATTIE, Professor of Bacteriology at Sheffield University since 1946.

Professor E. STENGEL, Professor of Psychiatry at Sheffield University since 1956.

Professor J. M. YOFFEY, Professor of Anatomy at Bristol University since 1941.

Medical Research in Scotland

The Scottish Hospital Endowments Research Trust has made a grant of £11,730 over three years to Mr. J. HUGHES, University of Strathclyde, for research into body-powered lower limb prostheses. Others to receive support for projects are: Dr. H. W. SUTHERLAND, Aberdeen University, intravenous tolerance tests, £1,156 for one year in the first instance; and Professor L. L. ENGEL, Macfarlane Chair of Experimental Medicine, Glasgow University, biochemistry of endocrine neoplasms, £2,000.

Study of Insect Carriers

A new centre for the study of insect carriers of tropical diseases is to be built. It will be the headquarters of the Government's service for this study. The Ministry of Overseas Development has made a grant of £45,000 to cover the cost of the building and the work of the service over the next three years. Until recently the work was done at the Lister Institute of Preventive Medicine, Elstree. The new centre will be at the Imperial College of Science's Field Station, Silwood Park, near Ascot.

U.S. Immigration Policy

The American Embassy in London confirmed last week that it would become increasingly difficult for a British graduate to obtain an immigrant's visa. Referring to the new immigration laws, which come into effect on 1 July next, the spokesman said: "Anyone who has not filed a petition at least three months before 30 June will probably have to wait two to three years. It will be a case of first come, first served, based on the date on which a petition is filed."

Under the new amendments the present system of national quotas is replaced by a

world-wide system of "preference categories." Medical graduates are in the third category, which includes members of the professions and people with exceptional skills. The number of immigrants entering the United States from this category would be 17,000 each year.

Maccabean Prize and Medal

Entries for the 1968 Maccabean Prize (25 guineas) and Medal are invited for an essay of 5,000 to 7,000 words on some aspect of the history of medicine or pharmacy. Candidates must be under 30 years of age on 15 March 1968. Further details can be obtained from Dr. F. N. L. POYNTER, Wellcome Historical Medical Library, Wellcome Building, Euston Road, London N.W.1.

James Mackenzie Prize 1967

Dr. M. B. CLYNE, Southall, Middlesex, has been awarded the James Mackenzie Prize 1967 in recognition of his studies of diseases common in practice and of present-day conditions of general practice and the operational problems facing the family doctor. Dr. Clyne is the third recipient of this prize.

New Chair at Dundee

Dr. P. D. GRIFFITHS has been appointed to the new chair of clinical chemistry at the University of Dundee. He is at present the senior lecturer in the department. Dr. Griffiths, who is 40, was educated at Guy's Hospital Medical School. He graduated B.Sc. in physiology with first-class honours in 1953, and proceeded to M.B., B.S. in 1956. Following house appointments at Guy's and New Cross General Hospital he entered the department of physiology at Guy's, and later moved to the department of clinical pathology. He was appointed a consultant pathologist to the Harlow Group of Hospitals in 1964, and took up his present post in Dundee last year. He holds the M.D. (Lond.) and is a member of the College of Pathologists. His research interests include muscle enzymology, genetics, and the medical uses of computers.

**Career in Hospital Administration**

Opportunities for training in hospital administration are announced by the Ministry of Health. Details and forms of application can be obtained from the National Staff Committee, 16-19 Gresse Street, London W.1; in Scotland from the Scottish Hospital Administrative Staffs Committee, Woodburn House, Canaan Lane, Edinburgh 10.

Medical Directory for Nigeria

The *Nigerian Medical Directory 1967-8* provides lists of doctors, dentists, and opticians throughout the Federal Republic. It also records hospitals, medical schools, and drug and equipment centres. A feature is a symposium, "Progress in Medicine," which describes advances made in the specialties during the year. The editor is Dr. V. O. AWOSIKA, whose address is P.O. Box 70, Ikeja, Nigeria.

People in the News

► Professor MICHAEL ABERCROMBIE, F.R.S., has been appointed to succeed DAME HONOR FELL, F.R.S., as director of the Strangeways Research Laboratory, Cambridge.

► Professor L. VANDENDRIESSCHE, professor of the faculty of medicine of the University of Ghent, has been appointed Belgian visiting professor for the session 1967-8. He will work in the biochemistry department at University College, London.

► Professor H. ORISHEJOLOMI THOMAS has been appointed provost of the College of Medicine, University of Lagos, Nigeria.

► Dr. MERVYN GOTSMAN has been appointed to the chair of cardiology at the University of Natal in Durban.

Grants and Awards

Professor J. A. ROPER, of Sheffield University, has received a grant of £3,218 from the Medical Research Council for research into genetic instability.

The Wellcome Trust is to make a grant of £2,200 to the physiology department at Univer-

sity College, Dublin, in support of special studies into the action of the heart.

Recent Publications

Notes on the Law Relating to Experiments on Animals in Great Britain (third edition) issued by the Research Defence Society, 11 Chandos Street, London W.1, 1s. 6d.

The *B.S. Yearbook for 1967* provides a reference to all British standards published up to 31 December 1966 (15s.). It forms a companion volume to the *Annual Report*, which covers the period 1 April 1966 to 31 March 1967 (10s.). British Standards Institution, 2 Park Street, London W.1.

Coming Events

Institute of Diseases of the Chest.—Clinical demonstrations, open to medical practitioners without fee, will be held in the Lecture Theatre of the Institute (in the grounds of the Brompton Hospital, Fulham Road, London S.W.3) on Fridays at 5 p.m. from 12 January to 15 March inclusive.

King Edward's Hospital Fund for London.—Conference, "Hospital Bed Usage," 16 January, Hospital Centre, 24 Nutford Place, London W.1. Fee £1. Completed application forms by 5 January. This conference is the third of a series of three on making better use of hospital resources.

International Union Against Cancer and Swiss Cancer League.—Conference on thyroid cancer, 8-10 May 1968, Lausanne. Details from Professor G. CANDARDJIS, Institut Universitaire de Radiologie Médicale, Hôpital Cantonal, 1005 Lausanne, Switzerland.

18th Congress of the International Association for Bronchial Studies.—13-16 June, Uppsala, Sweden. Details from Congressus Bronchologicus, Lungkliniken, Akademiska sjukhuset, Uppsala 14, Sweden.

1st International Symposium on Metabolism and Membrane Permeability of Erythrocytes and Thrombocytes.—17-20 June 1968, Vienna. Details from the Secretariat, Wiener Medizinische Akademie, Stadiongasse 6-8, 1010 Vienna, Austria.

Societies and Lectures

For attending lectures marked ● a fee is charged or a ticket is required. Applications should be made first to the institution concerned.

Monday, 18 December

CHELMSFORD MEDICAL EDUCATION AND RESEARCH TRUST.—At Chelmsford Medical Academic Unit, London Road (grounds of Chelmsford and Essex Hospital), 5.30 p.m., clinical meeting.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY.—5.30 p.m., combined staff consultation clinical meeting.

MANCHESTER MEDICAL SOCIETY: SECTION OF GENERAL PRACTICE.—At Large Anatomy Theatre, Manchester University Medical School, 9 p.m., Dr. L. Watt: Control of Venereal Infection.

Tuesday, 19 December

ROYAL POSTGRADUATE MEDICAL SCHOOL.—4 p.m., Mr. R. H. Franklin: Hiatus Hernia.

Wednesday, 20 December

CHELMSFORD MEDICAL EDUCATION AND RESEARCH TRUST.—At Chelmsford Medical Academic Unit, London Road (grounds of Chelmsford and Essex Hospital), 12 noon, surgical meeting.

WHITTINGTON HOSPITAL.—At Academic Centre, Archway Wing, London N., 11.30 a.m., Professor T. A. J. Prankerd: Haemorrhagic Diseases and their Treatment.

Universities and Colleges**LONDON**

Dr. S. Gnessen has been nominated for appointment or reappointment as a representative of the university on the governing body of Dalston and Mount Pleasant Secondary Schools.

SHEFFIELD

Appointment.—Dr. K. G. Wormsley (senior lecturer in the Department of Surgery with the title of senior lecturer in gastroenterology).

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS OF GLASGOW

On 4 December the following were admitted Fellows *qua* Physician:

J. W. Affleck, T. B. Begg, I. A. Boyd, W. I. Card, A. Dunn, W. S. Gardner, B. R. Hillis, J. G. P. Hutchison, K. G. Lowe, A. Lyell, G. P. McNicol, M. W. McNicol, W. A. Parker, D. A. Seaton, J. Smith, J. MacL. Smith, M. B. Urs, R. S. Walker, D. H. Wallace, W. G. Whyte, G. Will, G. M. Wilson, R. B. Wilson.

Members *qua* Physician:

C. S. Cheung, D. L. Davies, A. I. E. Bey, M. E. E. Sarraj, J. B. Familul, P. K. Ghatak, A. K. M. B. Karim, C. K. Narain, K. A. Paulsen, F. M. Pope, T. H. Sia.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At a meeting of the College held on 1 December, with the President, Professor Alan Thompson, in the chair, the following were admitted to the Membership:

R. A. Erinjery, R. S. Matthews, M. X. M. MacGeralt, J. A. O'Sullivan, J. J. Robb.

The following candidates were admitted to the Licence in Medicine and Obstetrics:

R. Bhaggeerutty, R. W. Charles G. A. J. Fernandes, H. Govind, E. E. Hansrod, E. O. E. Isong, A. H. M. Jiwan, M. J. Khetani, S.-L. Lau, M. A. Molake, L. A. Mosuro, D. K. Naidoo, A. O. Ogunola, B. M. Sandy.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council held on 25 November the following awards were made for 1968: *Edgar Gentili prize*, Dr. R. A. Diamond (Oxford); *William Blair-Bell Memorial lecture-ship*, Dr. R. J. Hunter (Belfast); *Eden Fellowship in obstetrics and gynaecology*, Dr. Mary G. Coyle (Dundee).

The following were admitted to the Membership *in absentia*:

K. H. Atkinson, G. C. Bird, L. J. H. Butterfield, G. J. Dennerstein, J. A. Hill, S. G. Kovacs, R. Lawrence, J. Ludlow, R. Luthra, P. N. McGuire, P. M. Renou, D. M. Saunders, J. E. Scott, A. Singer.

Notice to Authors

When original articles and letters for publication are not submitted exclusively to the *British Medical Journal* this must be stated.

Correspondence on editorial business should be addressed to the Editor, *British Medical Journal*, B.M.A. House, Tavistock Square, London W.C.1. Telephone: 01-387 4499. Telegrams: *Aitiology*, London W.C.1.

Authors wanting reprints of their articles should notify the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs.

Members' subscriptions should be sent to the Secretary of the British Medical Association, B.M.A. House, London, or to the Scottish Secretary, B.M.A. Scottish Office, Drumsheugh Gardens, Edinburgh.

Information on advertisement and subscription orders appear at the first page of the classified advertisements.

Pointers

Urinary Bacteriology in Children: Standards suggested for cell and bacteria counts for diagnosis of clinically unrecognized urinary tract infection in childhood, using plastic bag and midstream specimen methods of collection (p. 697). Accuracy of diagnosis with methods of collection just described compares favourably with catheter specimens when aforementioned criteria are used (p. 702). "Clean catch" method for neonates appears to be a reliable method of sampling (p. 705). Leader at p. 691.

Contraception and Anaemia: Compared with a control group and group using intrauterine devices, women taking the "pill" had on the average higher haemoglobin and haematocrit levels. Increased blood viscosity may be related to thrombotic phenomena (p. 708).

Emotion and Ileitis: Nineteen patients with regional ileitis did not show the emotional factors usually considered to be related to psychosomatic illness (p. 711).

Community Health Screening: Evaluation of survey undertaken to assess anaemia in non-pregnant women indicated that high-risk groups are unlikely to attend selectively to any large extent (p. 714).

Criterion of Fibrinolysis: Test for estimating fibrin degradation products in serum showed a measurable level of these in majority of a group of apparently healthy subjects (p. 718).

Case Reports: Malignant tumour of brown fat in Turner's syndrome (p. 720). Mumps nephritis (p. 721).

Haematemesis: Diagnosis and management of bleeding from the upper gastrointestinal tract (p. 723).

Today's Drugs: Epsilon aminocaproic acid (p. 725).

Peritoneal Dialysis: Sterilization of dialysate by filtration (p. 728).

Metabolic Studies: Special cot for newborn infants described (p. 729).

"The Queen's": Queen Elizabeth Hospital for Children (London) celebrates its 100th anniversary (p. 733).

Renal Disease: R.C.P.'s views on training of specialists (p. 735).

Teaching in General Practice: Aims and methods discussed at conference (p. 736).

Computers: B.M.A. symposium on use of mathematics in medicine (p. 737).

Test Your Knowledge: Christmas quiz at p. 740.

G.M.S. Committee: Minister's intentions on pay-beds discussed (*Supplement*, p. 81).

Diagnosis of Pyelonephritis in Children

Pyelonephritis is a potentially serious condition in childhood, the diagnosis is apt to be missed, and delay in reaching it can be harmful.^{1 2} In infants and small children it is rare to find symptoms which point directly to its diagnosis. Therefore microscopy and culture of the urine should always be undertaken when there is no obvious explanation for their illness.

It is generally accepted that a diagnosis of pyelonephritis should be based on the finding of an increase of both leucocytes and living pathogenic bacteria in the urine. But the situation is not so simple. For example, though an excess of leucocytes may be found in the urine in acute nephritis, a significant number of pathogenic bacteria may occur in genuine pyelonephritis without an increase in the number of leucocytes. Interpretation of the cell count may be difficult if the urine contains large numbers of epithelial cells: the small cells from the tubular epithelium are often particularly difficult to distinguish from leucocytes unless special stains are used. Moreover, the bacteriologist must decide whether the growth of organisms is due to contamination or a genuine infection.

As a routine method of obtaining urine for cell count and culture, catheterization has been abandoned and the mid-stream or "clean-catch" specimen is generally used in adults and older children. But for infants and young children who cannot pass their urine to order other methods have to be used. In some centres percutaneous aspiration of the full bladder is done on newborn babies to obtain an uncontaminated specimen, but this technique has not found universal acceptance. In Britain most paediatricians use a plastic urine-collecting bag. An additional complication in the neonatal period is that during the first week of life there is a higher proportion of epithelial cells from the renal tubules in the urine than at any other time of life. Consequently it is not possible to use as standards of normal the results obtained for older children or adults.

In the *B.M.J.* this week three papers from Edinburgh describe attempts to define acceptable limits of normal for cell and bacterial counts at various ages and by different methods of collection. Dr. Gillian Cruickshank and Dr. Elizabeth Edmond (page 705) studied the cell and bacterial counts of midstream specimens of urine taken from a group of infants during the first week of life. There was little difference between the males and females except that in the females the number of squamous epithelial cells was higher than in the males. The excretion of renal tubular epithelial cells was highest on the first day and fell gradually until the sixth day. By using a special peroxidase stain³ these cells could be easily distinguished from leucocytes. Their results suggest that bacterial counts fewer than 10^5 organisms per ml. are usually due to contamination when a count of more than 10^5 is obtained the examination should be repeated on one or more occasions. Of the cell counts, 96% of fewer than 10 leucocytes per cu. mm. in uncentrifuged urine. The

gations may be used as a standard against which other methods can be assessed, but it seems unlikely that the individually supervised midstream specimen, as collected in this study, is suitable for routine purposes.

In another paper in this issue (page 697) Dr. H. Braude, Professor J. O. Forfar, Dr. J. C. Gould, and Dr. J. W. McLeod have examined cell and bacterial counts in a large series of normal infants and children, from the newborn up to the age of 14 years. They compared the results obtained using the adhesive plastic bag and taking a mid-stream specimen; and these two groups were further subdivided into those in which the skin received simple cleansing without antiseptics or antibiotics and those in which the skin was not cleansed. In every age group the cell count was higher in the female than the male, irrespective of the method of collection. In the females the bag specimens gave considerably higher cell counts than did the midstream urines, and it would seem that many of the cells counted as leucocytes were actually epithelial cells or possibly leucocytes derived from the urethra or vulva. The bacterial counts did not show a great difference between the males and females at any age. An important observation was that bacterial counts were higher

in those specimens collected after skin preparation than when no preparation was used. The bag specimens gave higher bacterial counts than the midstream urines. In another paper the same group (page 702) report using a slightly different approach by comparing paired catheter and non-catheter specimens in children suspected on clinical grounds of having pyelonephritis. A special technique of catheterization was used, similar to that described by J. W. McLeod and colleagues⁴ in paraplegics. They showed that the risk of a false positive diagnosis with the non-catheter specimens (plastic bag or midstream specimens) was much reduced by making a suitable adjustment to the limits of normal for cell and bacterial counts.

These data can now be used as a basis for reporting quantitatively cell and bacterial counts in infants and young children in the same manner as has become accepted practice in adults.

Substitutes for the Mitral Valve

Mitral incompetence is a clinical entity, but the variation in anatomical deformity found by the cardiac surgeon has prevented a uniform surgical solution. When mitral incompetence is due to destruction of tissue by subacute bacterial endocarditis or rupture of the chordae tendineae tethering the cusp edges the leaflets of the mitral valve remain relatively supple. This type of deformity is correctable by a plastic procedure such as plication of the cusps, narrowing the valve ring, or adding pericardial patches to deficient leaflets. Rheumatic mitral incompetence, though sometimes associated with supple leaflets, more commonly is due to rigid, fibrotic, or calcified cusps, and it can be corrected only by replacement of the entire valve mechanism.

Prosthetic valves of many types have been used for replacement of the mitral valve, but the only models to stand the test of time have been those embodying a ball or disc (Starr, Kay-Shiley) moving freely in a metal cage in systole and diastole. Relief of incompetence is immediate and the operative mortality is now low, but the incidence of thrombosis on the valve with embolism of fragments has been a continuing problem, and every patient has to have anticoagulant treatment with all its attendant complications. Thrombosis is known to begin where the metal parts of the prosthetic valve join the cloth ring that is used for stitching the valve into the heart. One development has been to cover all the metal with a plastic velour cloth, which becomes coated with endothelium and reduces the incidence of thrombosis and embolism dramatically.¹ The second approach has been to avoid metal cages altogether by replacing the destroyed mitral valve with a graft of human or animal valve. The technical problems of transplantation of a mitral valve from a cadaver into the mitral ring of a patient can be surmounted, but rejection of the homograft causes erosion and rupture of the chordae tendineae.²

The aortic valve has no chordae to rupture and attention has turned to inserting cadaver aortic valves upside down into the mitral area. The problem of maintaining the correct tension on the cusps has been solved by surrounding the homograft valve with a rigid or semi-rigid cloth framework and allowing it to project into the left atrium rather than into the ventricle. Homograft aortic valves from cadavers, however, are not easy to obtain and are always smaller than the dilated mitral valve rings into which they are to be inserted. These two objections do not apply to heterograft aortic valves from pigs and calves, and it has been shown by G. H. Wooler and his colleagues in Leeds that these can be used clinically with a low operative mortality and satisfactory maintenance of competence at the present interval of follow-up.³

Enthusiasm for putting human and animal aortic valves into the mitral ring has been stimulated by their successful insertion into the aortic area by D. N. Ross, B. G. Barratt-Boyes, J. P. Binet, and A. J. Gunning.⁴⁻⁷ This enthusiasm has been tempered by recollection of the history of homograft and heterograft replacement of the abdominal aorta, which had to be abandoned because of the frequency with which the grafts calcified and ruptured. Hopes that aortic valves would not behave similarly have been based on the fact that valve cusps are nourished from the blood stream and do not become infiltrated by the host tissue—like that which invades the dead aortic wall and becomes calcified. Longer term

⁸ Gunning, A. J., personal communication, 1967.

follow-up, however, suggests that history may be repeated; Ross and Gunning have now reported calcification extending from the aortic wall on to the valve cusps, producing stenosis of the graft.^{2,8} The present incidence of thrombosis and embolism associated with prosthetic valves may, it seems, be being avoided only at the cost of eventual stenosis of a graft.

A further development in this field is the use by Ross of the patient's own pulmonary valve to replace his destroyed mitral valve.² Such an autograft should persist as living tissue and so avoid the hazard of eventual calcification. The problem then becomes how best to replace the excised pulmonary valve.

It is not easy for a cardiac surgeon to decide which of the artificial mitral valves he should use today, and this explains his reluctance to advise mitral valve replacement unless the patient's disability is severe. Time will probably narrow his choice of valve to an improved prosthesis or a pulmonary autograft.

Amines and Migraine

Like its predecessor,¹ the second migraine symposium, which was held in London on 24 November, was a useful review both of the clinical and of the biochemical and pharmacological aspects of the condition. Once again the role of amines in migraine was one of the principal topics discussed. Tyramine and dopamine, which are present in certain foods, were reported to be able to induce severe headaches in patients taking monoamine oxidase inhibitors.²⁻⁴ Moreover, it was pointed out that many patients with migraine exclude from their diet foods such as chocolate and cheese, which contain varying amounts of tyramine and other amines. Patients who were apt to develop migraine if they ate these foods had been shown⁵ to develop a migrainous headache within 24 hours if given tyramine by mouth. Normally tyramine is prevented from gaining access to the general circulation by the action of monoamine oxidase in the gut and the liver. Hence a possible explanation for the production of migraine by dietary factors might be a relative lack of monoamine oxidase in these sites. There is no evidence of this, however, and histochemical staining of temporal artery biopsy specimens in an attack of migraine show a normal content of monoamine oxidase in the vascular wall.⁶ On the other hand, in-vitro studies on the adventitial layer of temporal artery taken from patients during an attack of migraine have shown a greater uptake of catecholamines than with temporal artery

removed from other patients undergoing craniotomy for cerebral tumours.

When catecholamines and ergotamines are added to human cerebral arterioles removed at craniotomy there is no response, though when either of these agents is added to somatic arterioles definite vasoconstriction occurs. This finding does not support the accepted idea that the aura of migraine is due to ischaemia as a result of vasoconstriction⁷—unless vasoconstriction is a property of migrainous cerebral arterioles and not of normal ones. The therapeutic effect of ergotamine, however, is still thought to be due to its vasoconstrictor activity on the extracranial arteries,⁸ and the development of new compounds for the treatment of migraine is based on their in-vitro effects on blood vessels. Other important properties of any new drug are that its effects on non-vascular smooth muscle, such as the uterus, should be minimal and that it should not induce nausea.⁹

The relationship of migraine to menstruation and to pregnancy suggests that hormones may also play a part in the condition, directly or indirectly. The results of treatment with oestrogens have been disappointing,¹⁰⁻¹² and androgenic steroids have also been unsuccessful.¹²⁻¹⁶ Parenteral injections of progestogens are sometimes more effective, though the effect is of short duration. Giving progestogens by mouth, on the other hand, has had disappointing results,¹⁷ despite some benefit having been reported previously.¹⁸ Migraine remains an enigma, but further work on these biochemical and pharmacological aspects may help in its elucidation.

Life after Death

Man's response to the approach of death has a perennial fascination. In part this may rest in a false hope that by understanding its immediate antecedents we may come to know something of the nature of death. Sometimes the threat comes from outside—for instance, earthquake, battle, falls from great heights—and can be apprehended clearly. Men vary in their response to these experiences¹: some remain calm and can continue to perceive their predicament in detail, while others develop fear of such intensity that awareness becomes clouded and behaviour incoherent, and yet others develop amnesia and other hysterical symptoms.

Illness is a threat to life which comes from within. The patient who has a serious heart disease is in a psychological as well as a physical predicament. He is aware of his heart to a greater extent than any of his other vital organs; he is aware of it as something which moves and thus epitomizes life. This internal threat to life cannot be countered as can many threats to life from outside, but at the same time the patient has not the reassurance that matters are entirely out of his hands, since he recognizes that intemperate activity endangers him.

R. G. Druss and D. S. Kornfeld² have recently described the psychiatric sequelae of cardiac arrest and compared these with the response of patients to other forms of heart disease. The only difference found was that patients whose hearts had stopped subsequently experienced nightmares of violence—as do those who have been wounded in battle. The significance of these nightmares is not yet known. They may be an

³ *The Times*, 13 December 1967.

adaptive process—a catharsis—which enables the patient to adjust to his experience; or the distorted, fragmentary, and purposeless appearance of recent memories which emerge when repression is in abeyance during sleep; or the result of a subtle organic disturbance, with their content derived from recent experience. Neurotic reactions were found in almost all the patients with grave heart disease whether or not they had suffered cardiac arrest, but as the criteria of abnormality were not clearly defined any comparison with the incidence found in other studies is difficult.

These problems are likely to become more common as apparatus is developed which can take over other vital functions in patients who are seriously ill. Victims of accidents can be maintained alive by respirators³ until it becomes clear, whether or not the brain is going to recover. In these cases the borderline between life and death is becoming blurred.

The atmosphere of an intensive care unit heightens suggestibility. The patient is anxious, and he is in the presence of others, both staff and fellow patients, who are also likely to be anxious. He is surrounded by equipment to which contemporary mythology attributes magical powers. Druss and Kornfeld advise that patients should be allowed as much privacy as is feasible, that monitoring equipment should be placed inconspicuously, and that patients should not be aware of the monitor signal. Patients gain relief from talking about their worries and they should be given the opportunity to do this while they are in hospital and their experiences are still fresh. Druss and Kornfeld also advocate that: "the patients should be told that their bodies were alive during the time their hearts had stopped." Many would disagree with this advice. The fantasy of having been dead may arise spontaneously, but it may also be suggested by the doctor's attitudes and by this type of comment. Confronting the patient with the information that his heart stopped beating or that he stopped breathing could do harm. The physician's detailed understanding of the emergency has served its purpose if it has helped the patient to get better; it is not part of treatment that this knowledge should be shared.

Doctors in Court

The protection of a doctor's professional confidence must sometimes conflict with the interest of justice in discovering the truth. The law resolves that conflict in all except a few special cases by giving the trial judge power to use the ultimate deterrent of committal for contempt to enforce disclosure of the confidence, while enjoining the judge to be sparing in the use of that deterrent.

In a report published last week the Law Reform Committee recommended¹ no change in the law so far as it affects doctors in civil cases. The Criminal Law Revision Committee is apparently thinking along similar lines in its consideration of the criminal law. The only change at present envisaged might arise out of the deliberations of Lord Justice Winn's Committee on Personal Injury Litigation, which is considering whether the "privilege in aid of litigation" should continue to apply to certain classes of hospital and other medical reports. At present a medical report prepared at the request of the legal advisers of a litigant for the purpose of litigation need not be disclosed to the court.

Much can be said in favour of the present state of the law.²

Difficulties of definition alone make it almost impossible to set out the cases in which the professional man should be permitted to refuse to answer questions. The Committee's report shows how difficult it is to describe broad principles to cover this point. When considering how the court should exercise its discretion on the issue of compelling medical witnesses the Committee states:

"Where a doctor is called, not in his capacity as a medical adviser to testify as to the physical or mental condition of his patient, but as a witness of another fact not related to the health of his patient, we are confident that any judge would protect him from being questioned upon information obtained by him from his patient in his capacity of medical adviser."

The Committee suggests, for example, that a doctor should not be compelled to give evidence of an admission of adultery if the admission had no bearing on the patient's mental or physical health. The reverse of this proposition is probably more attractive to doctors. One can see the public interest in preserving secrecy about disclosures which are of assistance to a doctor in his care of his patient. There is much less (if any) public interest in protecting those disclosures made as incidental conversation at the time the patient sought treatment.

What is plain is that if the law is to remain in its present fluid state some better system of appeals from the ruling of the court should be considered. Since the right of confidence belongs to the patient and not to the doctor, the medical witness cannot be sure of his position until the patient's absence of consent to disclosure and the mood of the judge are revealed when the doctor is in the witness-box. It is not until the witness is in contempt of court by refusing to comply with an order to answer that he acquires any standing before the court to test the ruling on appeal. An adjournment for an immediate application to the Court of Appeal for a second ruling could probably be obtained even under the present Rules of Court, but it would require a firm advocate to persuade most judges to accede to such a course in the middle of a trial. It is a pity that the Law Reform Committee did not consider the procedural problems of ensuring that there are adequate means of appeal from the exercise of the existing wide judicial discretion.

Foot-and-mouth Disease

Few can fail to be shocked at the slaughter of nearly 300,000 animals in the current outbreak of foot-and-mouth disease. But this is the price that must be paid to keep Britain free from endemic infection with it. The disease is endemic in most countries of the world, and though Australia, New Zealand, North America, and Britain are normally free from it¹ the most rigorous measures of control must be employed to prevent the introduction and establishment of infection.

Foot-and-mouth disease is an extremely infectious viral disease of animals. Very rarely it also attacks man.^{2,3} It has a high attack rate in susceptible animals and a capacity for rapid spread comparable to human influenza. It affects cloven-footed animals such as cattle, sheep, pigs, and goats. The incubation period is from three to eight days, and the main route of infection is the respiratory tract. The virus causes a generalized infection, with vesicles on the tongue, mouth, and hooves, so that affected animals have increased salivation and lameness. Virus is excreted in large quantities in the saliva, and is present—though not in such large amounts

¹ *Sixteenth Report of Law Reform Committee, 1967, Cmd. 3472. H.M.S.O., London.*

² *Brit. med. J.*, 1964, 2, 955.

—in milk and urine also. Mortality is low in adult animals, but survivors take a long time to recover condition and show a high incidence of abortion and mastitis. In the high-production livestock industry in Britain such animals would be uneconomic. Surviving animals carry the virus for 15 to 18 months after infection.⁴ The virus is hardy and can survive for 14 days on wool and for about three months on boot leather, rubber boots, and hay,⁵ though it is rapidly inactivated by heat, sunlight, or by treatment with formaldehyde, sodium hydroxide, or—more slowly—sodium carbonate. It remains viable in frozen liver, kidney, glandular tissue, and bone, but is inactivated in muscle during rigor mortis.

The sources of importation of the virus into the country often remain obscure. Most outbreaks in Britain have been attributed to contaminated meat imported from countries where infection is endemic, but birds migrating from Europe were thought to have been responsible for introducing infection during the extensive outbreak in Britain in 1951–2, since it coincided with a large-scale epidemic in Europe and with mass bird migration to this country.⁶ When an outbreak starts it may spread from farm to farm through movement of infected animals, contaminated equipment, and products, or possibly by airborne dissemination of the virus.

The difficulties of controlling such a disease are obvious, and ruthless measures must be adopted. These include isolation with restriction of movement to and from farms in a wide area surrounding a focus of infection, together with disinfection and the elimination of susceptible animals which may have been in contact with infection. Unfortunately, vaccination, though successful in so many human infections, is fraught with difficulties when applied to the control of foot-and-mouth disease. For example, the protection conferred by primary vaccination in cattle is short-lived—from about two to six months—and even after revaccination immunity cannot be depended upon for more than a year.⁷ In pigs it is even more difficult to get a satisfactory immunity by vaccination. The second problem is the diversity of serological types of virus. There are seven main viral types, subdivided into at least 40 different subtypes or strains, and immunity to one strain within a type may not give complete protection against other strains within the same type.⁴ The most serious drawback, however, is that though vaccinated animals are protected against clinical disease they may acquire symptomless or masked infection and become carriers of the virus.⁸ This would greatly increase the difficulties of eradicating the disease. If vaccination were introduced here it might mean having to accept endemic infection in Britain.

Over the years the compensation paid to farmers in Britain as a result of the slaughter policy has been far less than the cost of vaccinating the 40 million susceptible domestic animals. So in 1967, as in 1952, the price of freedom from endemic infection is a heavy one. To medical men foot-and-mouth disease serves as a timely reminder that, despite striking advances in our knowledge of micro-organisms in recent years, infectious disease can still pose a threat not only to health but to a nation's economy.

Symposium on Thyrotoxicosis

The proceedings of an international symposium on thyrotoxicosis held in Edinburgh in May 1967 are now published.¹ The editor, W. J. Irvine, who also organized the symposium, is to be congratulated on the speed at which publication has been achieved. Many new developments in thyrotoxicosis are discussed.

The concept of the long-acting thyroid stimulator (L.A.T.S.) and its role in the pathogenesis of Graves's disease dominated the conference. L.A.T.S. is a member of the IgG class of serum proteins, most of which are antibodies. D. S. Munro and his colleagues reported that the thyroid-stimulating properties of L.A.T.S. are inherent in the IgG molecule. J. M. McKenzie, following on his previous demonstration that L.A.T.S. can be produced by the lymphocytes of patients with Graves's disease, showed that a long-acting thyroid stimulator could be produced in rabbits immunized with human thyroid. Like human L.A.T.S., this rabbit antibody increased the thyroid uptake of iodine-131, and the rate of release of thyroid iodine-131 was not suppressed by thyroid hormone. D. J. El Kabir and his associates showed that L.A.T.S. could be completely absorbed by thyroid tissue (but not by kidney) and subsequently eluted by techniques known to dissociate antigen-antibody complexes. It is likely that L.A.T.S. is an antibody produced by lymphocytes to some thyroid-specific antigen and is a major factor in the pathogenesis of Graves's disease. But indirect evidence discussed by R. Hall and his colleagues of the absence of L.A.T.S. in some patients with the ophthalmic form of Graves's disease is further evidence that some other factors, perhaps immune globulins as yet unrecognized, may be primarily responsible for the ophthalmopathy. Work on an exophthalmos-producing substance assayed in fishes² was discussed by P. J. der Kinderen. It is known to be distinct from L.A.T.S.

Conventional laboratory tests for the confirmation of a diagnosis of hyperthyroidism are often interfered with by drugs, especially those like the contraceptive pill, which affect the level of thyroxine-binding globulin (T.B.G.). Further simple methods of estimating the degree of saturation of this substance in the patient's serum were described by Irvine and his colleagues and by A. W. G. Goolden. These techniques, when combined with estimation of the protein-bound iodine, allow calculation of a free thyroxine factor which is independent of any changes in T.B.G. capacity. This type of test is particularly useful in the diagnosis of hyperthyroidism during pregnancy.

Important advances in the treatment of hyperthyroidism were reported. W. D. Alexander and R. McG. Harden found that patients treated with antithyroid drugs could be divided into two groups on the basis of their response to triiodothyronine. If this work is confirmed it may be possible to predict which patients will respond to a short course of antithyroid drugs and which will require alternative treatment such as surgery or radioactive iodine. With regard to surgery for thyrotoxicosis, Irvine and A. G. Stewart showed that patients with moderate to high titres of antibody to thyroid microsomes before operation stand about a one-in-four risk of developing hypothyroidism. Their conclusions are that such high antibody titres are a relative contraindication to

partial thyroidectomy, but that if thyroidectomy is carried out careful follow-up is obligatory. R. N. Smith and G. M. Wilson reviewed their long-term experience of radioactive iodine therapy for thyrotoxicosis. Using half the conventional dose of iodine-131 (about 3,500 rads) reduces the hypothyroid rate to 7% after five years but by itself is insufficient to control hyperthyroidism within a year in the majority of patients, who require additional therapy with antithyroid drugs. S. C. Werner described the use of prednisone in the treatment of the severe eye changes of Graves's disease. There appears to be a critical dosage which must be exceeded before benefit ensues, and it varies from patient to patient. Total thyroidectomy, a procedure difficult to achieve, did not arrest the progression of active severe eye changes in five patients.

The symposium embodied much that is new in relation to the pathogenesis, diagnosis, and treatment of thyrotoxicosis, but the enigma of Graves's disease remains to stimulate research worker and clinician alike.

Polycythaemia and Chorea

The clinical manifestations of chorea are pathognomonic and often florid, but paradoxically the underlying pathological changes in the central nervous system are often inconspicuous and non-specific. Patchy cellular infiltrations, diffuse loss of nerve cells, and mild endarteritis may be present in the cortex, basal ganglia, brain stem, and cerebellum, but obvious macroscopical changes are usually lacking. Chorea is usually associated with rheumatism or degenerative disease of the brain when it is refractory to treatment; but recently P. C. Gautier-Smith and T. A. J. Pranker¹ have drawn attention to the uncommon association of chorea and polycythaemia. Their experience suggests that both the neurological and the haematological response to appropriate treatment may be gratifying. One polycythaemic patient who had had Sydenham's chorea as a child developed transient cerebral ischaemic attacks and chorea. Initial treatment by venesection and intravenous ³²P induced a neurological remission and lowered the level of haemoglobin. When the involuntary movements and polycythaemia recurred they again responded satisfactorily to treatment. In a second polycythaemic patient, however, bilateral chorea of sudden onset improved spontaneously before the haematological diagnosis was established.

Cerebrovascular symptoms and lesions are common in polycythaemia but the occurrence of chorea is very rare. In one necropsy study² of polycythaemia distended and thrombosed veins with areas of demyelination were found to be scattered diffusely throughout the brain with no predilection for the basal ganglia. The pathogenic mechanisms causing cerebral dysfunction are usually considered to be the increased viscosity of the blood leading to raised vascular resistance and sometimes thrombus formation; but the

apparent reversibility of cerebral symptoms, including chorea, suggests that anoxia secondary to a sluggish circulation may be as important as multifocal irremediable infarctions. Though the critical combination of diffuse lesions responsible for the release of choreic movements remains obscure these case reports serve to remind clinicians that polycythaemia should not be overlooked in the investigation of cerebrovascular disease.

M.I.A. Jubilee

While the excellent service the Medical Insurance Agency renders the medical profession needs no embellishment, many doctors may be surprised to know that its support of medical charities is on as grand a scale. As a profession we are thus doubly grateful to note that the M.I.A. has now completed its first sixty years, an occasion celebrated by a diamond jubilee dinner held at B.M.A. House last week (see p. 755).

This non-profit-making agency has contributed more than £600,000 to charities over the years. The main recipients have been the Royal Medical Benevolent Fund, the Royal Medical Foundation of Epsom College, and the B.M.A. Charities Fund. Through them countless doctors and their families have been tided over desperate circumstances and their children often enabled to continue their education. In the present year alone the M.I.A. has contributed over £50,000 to medical charities.

The origin of this remarkable organization lies in a lunch-time conversation between Dawson Williams and Squire Sprigge, then the editors of the *B.M.J.* and *Lancet*. From experience of life assurance policies being effected by medical men they concluded that an organization should be set up to obtain the best possible terms, and that the whole of its surplus should be devoted to medical charities. This idea was put to the B.M.A., which, after investigating it further, agreed in 1907 to give the proposed scheme every assistance. The friendliest relations between the B.M.A. and the Medical Insurance Agency have continued till the present day and assuredly will for at least the next 60 years.

Return to Britain

A hard-pressed profession will welcome the Minister of Health's statement (see p. 753) that arrangements for the return of some 50 British doctors now in North America are well in hand. These doctors could ill be spared when they left and the need for them since has if anything increased. What experiences abroad or arguments by the Ministry's interviewing board¹ have decided them to come back are yet to be learnt. One thing, however, is certain: prompt news of home vacancies is essential for anyone contemplating this move. Doctors so placed will find helpful the *B.M.J.*'s air-mail lists of appointments. Details of this service, which started in 1953, are given at p. 756 of this issue.

Brit. med. J., 1967, 4, 697-701

Unrecognized urinary tract infection in infancy and childhood may have serious long-term effects, and chronic adult pyelonephritis may originate undetected at this time. The accurate diagnosis of urinary tract infection in the infant and child is thus important. It is usually based on assessment of the number of pus cells or bacteria in the urine, or both. In the case of cells, contamination from the urethra and periurethral area can increase the number falsely, and in an alkaline urine the rapid disappearance of cells can result in a falsely low count. With bacteria, contamination may occur from the perineal skin during collection; and multiplication will occur in a urine left standing. Antibiotics or chemotherapeutic agents may invalidate bacterial counts as diagnostic tests.

The object of the present study was to determine the cell and bacterial counts on urine collected from normal children by commonly used methods and to contrast the findings.

Material and Methods

Seven hundred and ten specimens of urine were examined from 553 infants and children aged 0-14 years who were without any suggestion of urinary tract infection and who had not received antibiotics during the previous six weeks (Table I). Most had not had any antibiotic.

The series included normal newborn infants in a maternity unit, medical and surgical inpatients in a paediatric department, and outpatients attending the same department.

Cell counts on the urine were carried out immediately after voiding, a few drops of homogenized urine being introduced into a Fuchs-Rosenthal counting-chamber. Where the identification of leucocytes was difficult one drop of acetic acid was added to a few millilitres of urine before introducing the urine into the counting-chamber, and further evidence of the presence of granular leucocytes was obtained where necessary by staining the sediment with Leishman's stain after centrifugation. In the neonatal period small non-squamous epithelial cells could significantly influence the cell count and were very difficult to differentiate from granular cells. Because of this, leucocytes and small non-squamous epithelial cells were counted together in the first 10 days of life.

For quantitative bacteriological examination a standard 3-mm. loopful of well-shaken unspun urine was plated and counted as described by Urquhart and Gould (1965).

pH was determined with wide range indicator papers.

Methods of Urine Collection

Bag Method.—Adhesive plastic bags obtainable commercially were used in the collection of specimens from infants in the 0-10 day and 11 days-2 years age groups (Table I). In some

infants the bag was attached without any previous skin cleansing (unprepared bag) and in others the perineum and external genitalia were well washed with sterile water beforehand (prepared bag). Antiseptics were not used. The bags were kept in position until the child passed urine and removed immediately or within a few minutes, the contents being transferred to a sterile wide-mouthed screw-capped universal container. Faecally contaminated urine was, of course, discarded. In a special group of 10 children aged 1-2 years 10 ml. of sterile water was introduced into the bag before it was applied and the bag removed at intervals ranging from 5 to 30 minutes for bacteriological examination of the contents before any urine had been passed into it.

Prepared M.S.U. ..	23	20	20	28	66	74	231
Total M.S.U.	48	40	62	65	133	142	490
Total bag and M.S.U. ..	119	96	104	116	133	142	710

Midstream Urines (M.S.U.s) or "Clean Catch" Specimens.—Midstream specimens were collected from patients in the 0-10 days, 11 days-2 years, and 2+-14 years age groups. The patients in these groups were further divided into those in whom no previous skin preparation had been carried out (unprepared M.S.U.) and those in whom previous to collection the perineum and external genitalia had been well washed with sterile water (prepared M.S.U.) (Table I). So far as was possible all specimens were caught in mid-air after allowing the initial few millilitres of urine to pass uncollected. With boys there was no serious difficulty, but there was with girls. When female infants void, the urine often wells up, forming a lake in the vulva and perineum. Sometimes the urine will be passed as a spray or drip off the posterior perineum. A strong jet may pass obliquely, striking the inner aspect of the thigh. Proper collection requires patience and time, but even with these, perfect collection is often not possible and in some cases specimens could not be obtained without bringing the mouth of the sterile container into contact with the skin. This was thought preferable to allowing the urine to flow over the

* Department of Child Life and Health, University of Edinburgh and Western General Hospital, Edinburgh.

† Central Microbiological Laboratories, Edinburgh.

perineal skin before collection. Young girls are often unable to pass urine on demand, and, particularly after any cleansing procedure, an hour or more may elapse before they will do so. Embarrassment commonly appears to be the dominant cause. Thus in the female infant and child many factors militate against the avoidance of contamination in the collection procedure.

Comparison of Methods of Collection on Same Patient

In 28 patients (11 males, 17 females) in the 0-2 year age group an unprepared bag specimen of urine was collected and then from the same patient on the same or following day a prepared specimen. In a further 58 cases (28 males, 30 females) in the same age group a bag specimen was collected followed on the same or the next day by a midstream specimen. In 33 patients (13 males, 20 females) in the 2+-14 year age group an unprepared M.S.U. was collected followed on the same or on the next day by a prepared M.S.U.

Bacterial Flora of Anterior Urethral Area

In 30 patients ranging from 0 to 14 years the anterior urethra was swabbed just before urine collection. Any organism isolated was considered in conjunction with any isolate from the urine specimen. Only organisms potentially pathogenic to the urinary tract were considered—namely, *Escherichia coli*, non-lactose fermenting coliforms, *Proteus*, *Streptococcus faecalis*, *Klebsiella*, *Pseudomonas pyocyanea*, and *Staphylococcus aureus*.

Results

Cell Counts

First 10 Days of Life.—Cell counts from 215 infants are shown in Tables II and III. In males some counts showed a moderate increase above 10 cells/cu. mm. for the first three days but thereafter fell well below this figure. In females the position was different. Throughout the 10-day period the counts tended to be high, 21% being above 10 cells/cu. mm. and 11% above 50 cells/cu. mm. The incidence of raised cell counts was higher in bag than in midstream urines. In bag urines from 56 females 27% were over 10/cu. mm., including 18% over 50/cu. mm. The corresponding figures for 40 M.S.U.s were 13% (P of difference=0.08) and 3% (P =0.01). In bag urines from 71 males 6% showed counts of over

			1.5%	11%
Bacterial counts > 10 ⁴ /ml.	..	..	8%	23%

10/cu. mm. Of the 142 females (all M.S.U.s) 11% exceeded 10/cu. mm., including 7% above 50/cu. mm. (Table V).

Bacterial Counts

First 10 Days of Life.—The incidence of bacterial counts for potentially pathogenic organisms in 215 specimens is shown in Tables II and III and contrasted in the former with the corresponding cell counts. The incidence of counts of 10^5 /ml. or over was high (40% male and 45% female) and unlike cell counts showed no significant sex difference. The overall incidence of 50% in 127 bag urines was higher than the 31% in 88 M.S.U.s ($P<0.01$).

First 2 Years of Life.—Apart from the comparison with cell counts in the first 10 days of life, bacterial counts in the first 10 days and in the remainder of the first two years need not be considered separately. There was no significant difference between them at these two periods. Table VI thus shows

TABLE VI.—Bacterial Counts (Potentially Pathogenic Organisms) per ml. on 710 Specimens of Urine from Children Aged 0–14 Years

			No. of Specimens	No Growth		10 ¹ –10 ⁴		10 ⁵ or Over		10 ⁶ or Over		10 ⁷ or Over	
				No.	%	No.	%	No.	%	No.	%	No.	%

		Total	275	192	70	40	15	43	16	17	6	6	2

bacterial counts for potentially pathogenic organisms for the whole of the first two years divided according to sex and method of collection. There was no significant sex difference in either bag urines or M.S.U.s. The incidence of bacterial counts of 10^5 or over/ml. was high, 49% for 108 bag urines and 34% for 73 M.S.U.s—a statistically significant difference ($P=0.001$). At 10^6 or over/ml. the incidences were 15% for bag urines and 3% for M.S.U.s ($P=0.03$) and at 10^7 /ml. 4% and nil ($P=0.001$). In the 58 cases in which a bag specimen was followed by an M.S.U. 66% showed a lower bacterial count with the M.S.U. (average difference= 10^2 organisms/ml.); 15% a lower count with the bag (average difference= 10^2 /ml.), and 19% similar. This is a significant difference ($P<0.00001$). The effect of the time interval between the application of the bag and the voiding of urine into it is shown in Table VII. Longer intervals made little difference, suggesting that contamination was already pronounced at less than half an hour. Where, in 10 children, bags containing sterile water were applied for periods of 5, 15, and 30 minutes all specimens of water produced a pure growth of *E. coli*, the average count at 5 and 15 minutes being 10^5 and at 30 minutes 10^6 .

TABLE VII.—Effect of Time Interval (Application of Bag to Passage of Urine) on Bacterial Count (All Organisms) (219 Children Aged 0–2 Years)

	< ½ Hour	½–1 Hour	1–2 Hours	> 2 Hours
No.	82	52	43	42
No. 10^5 or over	53 (65%)	28 (54%)	26 (61%)	30 (72%)

2+ to 14 Years.—The incidences of raised bacterial counts in 275 specimens are shown in Tables V and VI. Counts of 10^5 or over/ml. were significantly less frequent than in the 0–2 year group, 16% compared with 34% ($P<0.00001$), and the incidence of specimens in which there was no growth was significantly greater, 70% compared with 28% ($P<0.00001$). Paradoxically the incidence of bacterial counts of 10^6 or more/

ml. was significantly higher in females in this group than in M.S.U.s in the 0–2 year group. There was a significant sex difference within the group, 23% of females showing counts of 10^5 or higher/ml. compared with 8% of males ($P=0.001$).

Effect of Preparation on Bacterial Counts

Table VIII shows that with bag specimens in the 0–2 year group skin preparation with sterile water resulted in a significantly higher incidence of bacterial counts of 10^5 or over, 65% compared with 34% ($P=0.0001$). This applied to both sexes.

In the 28 cases in the 0–2 year group in which in the same patient a bag urine was collected without, and then with, previous preparation, the former showed a lower count in 46% of specimens (average difference= 10^3 organisms/ml.) and the latter in 14% of specimens (average difference= 10^2 organisms/ml.). This difference is significant ($P<0.01$) and was seen in both male and female children.

With M.S.U.s similar bacterial counts were obtained from unprepared and prepared specimens in the 0–2 year and 2+–14 year groups though at lower incidences in the latter. The similarity was evident in both sexes.

TABLE VIII.—Effect on Bacterial Count (Potentially Pathogenic Organisms per ml.) of Previous Preparation

			No.	No Growth		10^5 or Over		10^6 or Over		10^7 or Over	
				No.	%	No.	%	No.	%	No.	%
0–2 years	Bag	Unprep.	116	26	22	40	34	12	10	2	2
		Prep.	104	17	16	68	65	23	20	6	6
	M.S.U.	Unprep.	124	42	34	44	36	4	3	0	0
		Prep.	91	18	20	29	32	2	2	0	0
2+–14 years	M.S.U.	Unprep.	135	95	70	21	15	9	7	4	3
		Prep.	140	97	69	22	16	8	6	2	1

In the 33 cases in the 2+–14 year group in which in the same patient unprepared and then prepared M.S.U.s were examined, 6% of unprepared specimens had lower counts than prepared (average difference= 10^3 organisms/ml.) and 42% of prepared specimens lower counts than unprepared (average difference= 10^2 organisms/ml.). This is a significant difference ($P<0.001$).

Thus with bag urines preparation of the type described here before collection resulted in higher bacterial counts, while with M.S.U.s it did not affect or lowered the bacterial count.

Comparisons Between Organisms Isolated from the Anterior Urethra and from Corresponding Specimens of Urine

In 63% of the 30 cases examined similar organisms were cultured from the anterior urethra and from the urine and in 20% of cases different organisms. In 13% of cases the urine was sterile and in 3% no growth was obtained from the anterior

urethral swab. There is thus considerable correlation between bacterial flora found on the anterior urethral area and in the urine.

Organisms Cultured

The frequency with which the various potentially pathogenic organisms occurred was as follows: *E. coli* 60%, *Proteus* 28%, non-lactose fermenting coliforms 9%, *Ps. pyocyanea* and *Strep. faecalis* 1%, *Klebsiella* and *Staphylococcus aureus* less than 1%. Where potentially pathogenic organisms were associated with a bacterial count of 10^5 or more/ml. they were present in pure growth in 42% of cases in the 0-2 year group but in only 12% in the 2+–14 year group.

Correlation Between Cell Counts and Bacterial Counts

In the first 10 days of life the incidence of bacterial counts for potentially pathogenic organisms of 10^5 or over/ml. (42%) was very much higher than the incidence of cell counts of more than 10/cu. mm. (11%) or 50/cu. mm. (6%). For this period Table III shows the combined cell and bacterial counts at various levels. If the upper limit of the normal cell count is set at 50/cu. mm. and of the bacterial count at 10^4 /ml. only one M.S.U. (1%) was outside these limits. Of the bag urines 10 (8%) exceeded these limits, and if the upper accepted limit of the bacterial count is raised to 10^5 /ml. 5 (4%) did so. With the bag urines it was the females in particular (8 out of 10) who showed high combined counts.

In the 11 days to 2-year period (Table IV) none of the male patients gave specimens which exceeded the combined criteria of 10 cells/cu. mm. and 10^4 bacteria/ml. whether the urine was collected by bag or mid-stream. Nor did any of the female specimens collected as M.S.U.s exceed these limits, but eight of the bag urines in females (16%) did so.

In the 2+–14-year period (Table V) where all specimens were M.S.U.s none of the male specimens exceeded the limits of 10 cells/cu. mm. and 10^4 organisms/ml., but eight specimens from females (6%) lay outside these limits and five (3.5%) exceeded the combined criteria of 10 cells/cu. mm. and 10^5 bacteria/ml.

While there is thus a good deal of variability in the normal cell and bacterial counts in children it is possible from the data presented here to recognize upper limits of normal for cell counts alone, for bacterial counts alone, and for combined cell and bacterial counts for different age groups, and also for

different sexes and for different methods of collection. This has been done in Table IX where are represented "diagnostic levels" which generally just exceed these upper normal limits or in a few instances would be reached in less than 6% of normal children.

Discussion

It is important that urinary tract infection in infancy and childhood should be diagnosed early and confidently, yet the symptoms may be far from specific (Burke, 1961; Smellie *et al.*, 1964). Definitive diagnosis depends largely on examination of the urine for its cellular and bacterial content. The conditions under which this examination is made must be strictly defined, otherwise false and highly misleading results may be obtained. It is very likely that false-positive diagnoses are occurring to a considerable extent at present and that many children are given unnecessary and even harmful antibiotic treatment. Even more dangerous, particularly in infancy, is the possibility that wrongly presumed urinary tract infection may delay or mask the diagnosis of other more sinister disease. On the other hand, failure to diagnose urinary tract infection when it is present may have serious short-term and long-term effects.

Apart from bag collections over the first three days of life the cell count in the normal male child aged 0-14 years, whether urine is collected by bag or M.S.U., hardly ever exceeds 10/cu. mm. or in the case of M.S.U.s after the age of 11 days 5/cu. mm. Thus in the male infant the urinary cell count is a valuable diagnostic procedure.

In the female the position is less clear cut. Over the first 10 days of life high cell counts may be obtained normally due to the presence in the urine of small round non-squamous epithelial cells which are difficult to differentiate from pus cells on simple counting. Differentiation can usually be made by staining a film of the urinary sediment, but this is time-consuming. James (1959) suggested 50 cells/cu. mm. as the upper limit of normal at this age, but from our results a slightly higher level (75/cu. mm.) would be more appropriate with M.S.U.s and a count of over 300/cu. mm. for bag urines.

In female children aged 11 days to 2 years 24% of bag urines and 5% of M.S.U.s show cell counts in excess of 10/cu. mm. but few exceed 50 cells/cu. mm. At this age 50 cells/cu. mm. in M.S.U.s or double this number in bag urines represent the upper limits of normal. In the 2+–14 year age group in girls the cell count can commonly be high and counts of up to 150/cu. mm. can occur normally.

Midstream specimens are difficult to collect in young children and this has popularized the use of adhesive plastic

TABLE IX.—Diagnostic Levels in Children Aged 0-14 Years for Cell Counts Alone, Bacterial Counts Alone, and Combined Cell and Bacterial Counts. Urine Collected by Bags and as Midstream Specimens

bags. Bag urines, with bacterial counts on them, have been used in determining the incidence of urinary tract infection in childhood (Smellie *et al.*, 1964). Yet in the present study half of the urines collected in this way in normal infants of both sexes aged 0–2 years were found to produce bacterial counts for potentially pathogenic organisms of 10^5 /ml. and approximately 15% counts of 10^6 /ml. Similar results have been obtained by Lam *et al.* (1967) and Newman *et al.* (1967).

The evidence that bacterial counts on urine voided into a bag within half an hour of the bag being applied are as high as those where the bag has been applied for over two hours before voiding suggests that contamination of the urine takes place at the time that it is passed or of the bag at the time that it is applied. The high bacterial counts in the bags containing sterile water suggest that contact with the genitalia and skin of the perineum results in immediate contamination. Previous cleansing of the skin of the perineum and genitalia with sterile distilled water appeared to increase contamination, possibly by creating a "storm" of bacteria which might otherwise have lain dormant. More extensive irrigation, as practised by Lincoln and Winberg (1964), may reduce contamination.

It has been suggested that when urine is contaminated from the urethra or vulva the bacterial count is unlikely to exceed 10^4 /ml., but that where bacteria multiply in the bladder in genuine urinary tract infection they will reach levels of 10^6 or more/ml. (Kass, 1960). This may be true for the adult but is probably not valid for the infant and child, where the volume of urine is very much smaller and the amount of contamination is likely to be relatively very much greater. It is clear that the bacterial count of 10^5 /ml., which has attained such significance in the adult, is not valid as a dividing line between infected and non-infected urine in the child. Variations in age and sex, the effect of antiseptics used in skin cleansing, and the technique of collection all have to be considered in assessing results. Adult criteria are often misleading in the child, and criteria determined by one method of collection cannot be transposed to interpret results from another.

The normal limits for the diagnosis of urinary tract infection based on single cell or bacterial counts are wide but can be much more narrowly defined when cell and bacterial counts are considered in combination (Houston, 1963). Where M.S.U.s are collected as described here the combined limits of 10 cells/cu. mm. and 10^4 organisms/ml. which are so commonly used (Stansfeld, 1966) would hardly ever be exceeded in males and would be exceeded in only 4% of females. With bag urines under 3% of males and 16% of females would be outside the same limits, but if in females the combined limits are taken as 50 cells/cu. mm. and 10^5 bacteria/ml. less than 4% would lie outside these.

Urinary tract infection should, if possible, be diagnosed both by cell counts and by bacterial counts, repeating these observations and finding them constant, and finding, too, the same pathogenic organisms in pure growth on both occasions. Ideally a midstream specimen should be a true "clean catch" even if it takes several hours to obtain this. Unfortunately it may be impracticable to implement optimum diagnostic procedures. Treatment may have to be instituted without waiting for second specimens; it may be impossible to obtain a perfect midstream specimen; the very frequency with which urinary tract infection is suspected in children makes simple rapid methods of urine collection for diagnostic purposes obligatory. Under these circumstances it appears worth while to know the limits of single specimen observations, both when only the result of a cell count or a bacterial count is available and when combined

observations of cell and bacterial counts have been made on the specimen and can be considered together (Table IX).

With some of the criteria shown in Table IX there will be a small overlap between the findings in the normal child and those in the child with a urinary tract infection. Until absolute methods of diagnosis become possible such overlap is likely in any method of collection of urine passed per urethra. Precise definition of the limits of any method employed will increase its value and point to its limitations.

Summary

Normal cell and bacterial counts in urine obtained both by plastic adhesive bags and as midstream urines from male and female children from birth to 14 years have been determined by a study of 710 specimens obtained from 553 normal children.

At all ages cell counts were significantly higher in female than in male children when urine was collected by bag and as midstream specimens.

Until the age of 2 years bacterial counts were similar in male and in female children, but over the age of 2 years bacterial counts were higher in female children. These similarities and differences were seen in both bag and M.S.U.s.

Cell counts and bacterial counts in both males and females were significantly higher in urine obtained in bags as compared with M.S.U.s.

With midstream specimens previous preparation by washing the genital area with sterile distilled water did not affect the bacterial count up to the age of 2 years but reduced it in children over this age. With bags, previous preparation resulted in higher bacterial counts. There was evidence of rapid and significant contamination of urine collected by bag.

Organisms present on the anterior urethra were commonly the same as those isolated from urine specimens.

The pattern of distribution and upper limits of normal cell and bacterial counts in male and female infants at various ages for urine collected by bag and as midstream specimens are defined. On the basis of these definitions standards suggested for individual counts of cells and bacteria combined counts (on the same specimen) by which urinary tract infection in infancy and childhood can be made.

Diagnosis of Urinary Tract Infection in Childhood Based on Examination of Paired Non-catheter and Catheter Specimens of Urine

H. BRAUDE,* M.B., CH.B., M.R.C.P.ED., D.C.H.; J. O. FORFAR,* M.C., M.D., B.SC., F.R.C.P., F.R.C.P.ED., D.C.H.

Brit. med. J., 1967, 4, 702-705

The accurate diagnosis of urinary tract infection in infancy and childhood based on examination of the urine is made difficult by the number of variables involved. These include the age and sex of the patient, method of collection of the urine, time interval between micturition and urine examination, and technique of examination employed. The method of collection of urine is most important and for two common methods—plastic adhesive bags and midstream specimens—we have suggested diagnostic levels for cell and bacterial counts related to the age and sex of the patient and the type of collection (Braude *et al.*, 1967).

To determine the validity of these levels non-catheter and catheter specimens of urine were obtained from 68 patients.

Material

In most of the patients the suspicion had arisen on clinical grounds that urinary tract infection might be present—a suspicion based on suggestive symptoms such as abdominal pain, dysuria, frequency of micturition, enuresis, unexplained vomiting or anorexia, and, in the case of infants, unexplained failure to thrive. Also in a number of symptomless cases routine examination of the urine had suggested that infection might be present. Of the 68 patients 49 were female and 19 male. The ages ranged from 9 days to 11 years (see Table).

Methods

With the methods described by Braude *et al.* (1967) 92 non-catheter specimens—76 (82%) midstream and 16 (18%) bag—were obtained from 68 patients, and thereafter a catheter specimen was obtained from each of them. Catheterization was carried out by a modification of the technique described by Gould *et al.* (1963), which is effective in delaying urinary tract infection in paraplegic patients, often for many weeks, until change of catheter is made. The external genitalia, after being washed with sterile water and while still moist, are covered with Polybactrin (neomycin sulphate 495 mg., polymyxin B sulphate 150,000 units, zinc bacitracin 37,500 units, and cloxacillin 109 g. with a mixture of the inert and highly volatile dichlorotetrafluoroethane and dichlorodifluoroethane at a distance of 12 in. (30 cm.), the labia being retracted in the female and the foreskin retracted in the male. The area is then covered with a sterile towel.

The catheter is irrigated with aqueous Polybactrin Soluble (neomycin sulphate 495 mg., polymyxin B sulphate 150,000 units, zinc bacitracin 37,500 units per 2 ml. With the catheter fine enough to allow a free return of urine a sterile premature infant-feeding tube size 5 is inserted into the anterior urethra, in order to enter the anterior urethra and to be pushed up to $\frac{1}{2}$ in. (1.3 cm.). While the

operator holds the catheter in position an assistant slowly injects 2 ml. of solution. A return flow alongside the catheter should occur. (If it does not the catheter has been inserted too far and the solution is being injected into the bladder. This may modify bacteriological but not cytological results.) The catheter is then withdrawn and the patient left for half an hour. In young boys catheterization often causes discomfort and it is advisable to anaesthetize the posterior urethra before the second or main part of the catheterization procedure by introducing a little anaesthetic jelly (Duncaine) into the urethra immediately after the irrigation procedure.

After half an hour has elapsed the operator again scrubs up, and, holding the labia apart or retracting the foreskin, using sterile swabs, the genitalia are resprayed with Polybactrin as described above and the patient is retowelled. The operator puts on sterile gloves and catheterizes the bladder, using a sterile disposable plastic tube size 9 F.G. (feeding or umbilical tube) and a non-touch technique. The assistant, controlling the other end of the catheter with forceps, directs the urine into a sterile container. Normally a few drops are collected into a first bottle, which is discarded, and the remainder of the urine into a second. In small babies there may be little urine in the bladder, and under these circumstances the first bottle has to be used for bacteriological examinations.

Effect of Polybactrin Catheterization on Bacterial Growth in the Urine

In most cases the antibacterial activity of the urine obtained after catheterization was determined by means of indicator plates sown with an antibiotic-sensitive staphylococcus and filter-paper discs saturated with urine (Gould, 1965). Such activity was shown in 69% of specimens, and the average zone of elimination was 5–6 mm. This is a very limited antibacterial effect. Experience with this method shows that it is unusual to find bacterial counts in the lower range of 10^3 or 10^4 /ml. If a growth is obtained it is usually of the order of 10^5 or greater/ml. This clear differentiation is probably due to the mild antibacterial effect of the Polybactrin in the urine inhibiting growth of contaminants. With this technique a bacterial count of 10^4 or higher/ml. was considered to indicate infection.

As regards cell counts in catheterized patients infection was reckoned to be present if the count exceeded 10/cu. mm.

Results

Cell counts, bacterial counts, organisms cultured, and urinary pH are shown in the Table. The criteria for infection in catheter specimens were either or both of the cell and bacterial counts given above and, for non-catheterized specimens, one or more of the cell counts, bacterial counts, and combined cell and bacterial counts ("combined counts") given by Braude *et al.* (1967) as indicative of infection. In columns 7, 8, and 9 of the Table positive or negative signs indicate whether or not these criteria were met.

MSU = Midstream urine. C = Catheter urine.

In making comparison between catheter and non-catheter urines evidence of infection in the catheter urine was considered to indicate genuine infection (with the exception of two cases mentioned later).

Correlation between Non-catheter and Catheter Specimens

The technique of catheterization should reduce to a minimum contamination with cells and bacteria and growth of any contaminant. The Polybactrin may even have caused some reduction in the bacterial count in infected cases. Thirty-nine (57%) of the catheter urines showed no growth on culture. Twenty-nine (43%) showed a growth—two with counts of less than 10^3 /ml., one with a count of 10^4 /ml., and the remainder with counts of 10^5 or more/ml. In contrast only 3 of the 76 (4%) midstream urines showed no growth and none of the 16 bag urines did so. The bacterial count in these urines ranged much more widely.

The Table is divided into four groups. The first of these contains 23 cases in which the urine was thought to show evidence of infection in both catheter and non-catheter specimens. In all but three of the catheter specimens (87%) both cell count and bacterial count were "positive." In the non-catheter specimens all of the three possible criteria (cell count, bacterial count, and combined count) were positive in 9 cases (39%), two in 10 cases (44%), and one in 4 cases (17%). Combined counts alone were positive in 21 of the 23 cases (92%), cell counts in 19 cases (83%), and bacterial counts in 11 cases (48%). Thus combined counts were most effective and single bacterial counts least effective in diagnosis.

In all 23 infected cases a single species of pathogens was isolated in pure culture, and, apart from one case in which the organisms were different and two in which in the catheter specimen there was no growth, the same organism was found in the catheter and non-catheter specimens.

The second group in the Table consists of 31 cases in which there was no evidence of infection, according to the criteria indicated above, in either catheter or non-catheter specimens. In these cases, in contradistinction to the infected cases, there were 12 in which a mixed flora was isolated or different species were obtained from catheter and non-catheter urines.

In the third group in the Table are seven cases in which the non-catheter specimen showed evidence of infection but the catheter specimen was negative. In five of these (Cases 55, 56, 57, 58, and 60) it seemed likely that the non-catheter specimens had given false-positive results. The symptomatology was unconvincing, the criteria were only minimally positive, a subsequent specimen in two of them was negative or there was a mixed growth. In two (Cases 59 and 61) the findings in the non-catheter urine were probably correct. Both had symptoms very suggestive of urinary tract infection, and pure growths of *Escherichia coli* were obtained. One of them produced two positive non-catheter specimens, each with bacterial counts of 10^{10} /ml. Imperfections in the catheterization technique with the escape of Polybactrin into the bladder might account for the occurrence of occasional false bacteriological negatives in catheter specimens.

The fourth section of the Table comprises seven cases in which a non-catheter specimen was negative but the catheter specimen positive. In three of these (Cases 63, 64, and 67) the urinary pH was 8, 8, and 7 respectively and there was an absence of cells. Thus the alkaline pH may have created false negativity in the non-catheter urines by reducing the cell count. In Case 66 the symptoms were very suggestive of urinary tract infection, and in Case 68 the criteria in the non-catheter specimen of urine just missed being positive. In the remaining cases (Nos. 62 and 65) there was no additional supportive evidence in either direction and the catheter urine is thought to be the valid one.

Thus there was correspondence between catheter and non-catheter specimens in 54 of the 68 cases (80%). Excluding

Cases 59 and 61, five (7%) of the non-catheter specimens gave false-positive results and seven (10%) false-negative results.

As a check on the cases which were catheterized and thought to be non-infected three successive non-catheter specimens of urine were obtained from each six weeks later. These showed no evidence of infection.

Discussion

In the collection of urine from young children, particularly females, the use of adhesive plastic bags is the simplest procedure, but even when the bags are removed as soon as urine is passed into them a considerable amount of contamination has already occurred (Braude *et al.*, 1967). Ideal "clean-catch" midstream specimens from girls can at times be obtained only after many attempts and many hours of patience. Where such specimens are very carefully collected by specially trained nursing staff, after preparation of perineum and vulva with antiseptic solution, bacterial counts approximate to those found in specimens obtained by catheter and suprapubic aspiration (Pryles and Steg, 1959; Pryles *et al.*, 1959, 1961), but there are many circumstances where it is difficult or impossible to obtain such specimens—in the home, the busy outpatient department or ward, with refractory children. Criteria applicable to specimens obtained from adults and to "ideal" specimens from children are often widely applied to routine specimens, so that a false-positive diagnosis of urinary tract infection is a very frequent occurrence in paediatric practice. There does, therefore, appear to be a case for setting standards by which bag urines and midstream urines which may not be entirely ideal can be used in making the diagnosis of urinary tract infection.

Cell counts and pH must be on fresh specimens, and bacterial counts be carried out within half an hour of micturition, or if a longer time is to elapse the urine must be refrigerated at 4° C. This can be simply achieved during transmission to a laboratory by placing the specimen in its container in a vacuum flask containing an ice pack.

With these methods it seems likely that the diagnosis of urinary tract infection can be made in a high proportion of cases from examination of a single routine specimen of urine. If it is accepted that 32 of our cases were in fact suffering from urinary tract infection 25 (78%) were effectively diagnosed in this way. As regards the five false-positives, two showed a mixed growth in the urine, which should always raise diagnostic doubts, and in two a second non-catheter specimen was negative.

Of more importance are the seven (10%) false-negatives. Clearly if a certain amount of contamination is accepted in a large majority of specimens and standards for cell and bacterial counts are adjusted accordingly a specimen which, by accident as it were, is collected ideally may show lower cell and bacterial counts in the presence of infection, corresponding more to the standards in specimens obtained by catheter. A high urinary pH may also predispose to false negativity.

Recognizing that in a small number of infected cases cell and bacterial counts from single non-catheter specimens will not reach the diagnostic standards which have been set, there would need to be a safeguard in the use of these standards. We suggest a "re-examination" standard which, though it would not indicate infection, would indicate the need to obtain a further specimen of urine before a diagnosis could be made. A suitable standard for this would be a cell count of 10 or higher/cu. mm. combined with a bacterial count in males of 10^5 or more/ml. and in females of 10^6 or more/ml. That these standards are not suitable for making a diagnosis of urinary tract infection is shown by the fact that over 60% of the non-infected cases reached them.

The opinion is widely held that catheterization of the bladder is an important cause of urinary tract infection (Ansell, 1962). The risk of infection in children has probably been overstated

(Pryles *et al.*, 1959), though it was thought to be 7% in one series (Virtanen *et al.*, 1962). The method of catheterization which we have used has been widely and successfully employed in the catheterization of paraplegic patients, in whom the risk of infection is very high (McLeod *et al.*, 1963). Though catheterization of the urinary bladder is undesirable for other reasons as well as the possible risk of infection, there are instances where it is indicated. One of these would be continuing doubt about the diagnosis of urinary tract infection in children after the examination of non-catheter specimens. The method described here seems to be a safe and practical one.

Summary

Non-catheter (bag or midstream specimen) and catheter specimens of urine from 68 children suspected to be suffering from infection of the renal tract have been compared. Accepting the catheter specimen predominantly as the indicator of urinary tract infection, it was concluded that 32 children (47%) were suffering from pyelonephritis.

With the use of certain specified diagnostic criteria on single non-catheter specimens of urine 25 (78%) of the infected cases were diagnosed positively. In the 68 cases there were only five (7%) false-positives among the non-catheter specimens, suggest-

ing that the criteria used reduce significantly the high incidence of false-positive results which tends to occur with random non-catheter specimens.

Means by which false-negative results can be avoided include a "re-examination" standard and consideration of urinary pH.

A method of bladder catheterization in children with the use of a Polybactrin technique appears to be safe and can be used in cases where diagnoses cannot be readily established from non-catheter specimens.

J. W. M. wishes to thank the Royal Society for a grant for expenses, the M.R.C. for the provision of technical assistance, and Messrs. Calmic for supplies of Polybactrin G.U.

"Clean Catch" Urines in the Newborn—Bacteriology and Cell Excretion Patterns in First Week of Life

GILLIAN CRUICKSHANK,* M.B., B.CH., D.C.H.; ELIZABETH EDMOND,† M.B., CH.B.

Brit. med. J., 1967, **4**, 705-707

Urinary tract infection in the newborn may not be uncommon (Stansfeld, 1954, 1966; Lincoln and Winberg, 1964a; Smellie *et al.*, 1964). Clinical signs may be variable or absent, and diagnosis depends on the demonstration of a significant bacteriuria. However, in the absence of a reliable and simple method of collection of specimens diagnosis is difficult. Catheterization and suprapubic puncture are probably not acceptable as routine procedures (Pryles, 1965). The reliability of three supervised "clean catch" specimens of urine in the newborn has been assessed by bacteriological techniques, with particular reference to the problem of contamination. At the same time the urinary cell-excretion pattern in the first week of life was studied by means of a differential staining technique (Prescott and Brodie, 1964).

Method

Forty babies (21 male and 19 female) who were free from recognized infection and not receiving antibiotics were included in the study. Details of delivery and drug therapy in the mother were noted. A clean-catch specimen, personally supervised by one of us, was collected from each baby on the second, fourth, and sixth day of life. The buttocks and perineum were well cleansed with soap and water only, the labia were separated, but the foreskin was not retracted. The skin was dried with a sterile swab. The baby was supported with the

thighs abducted, and any urine passed was collected directly into a sterile container, which was not allowed to come into contact with the baby's skin at any time. If no urine was passed within 20 minutes the baby was rewashed or the collection postponed until a more opportune moment. Urine specimens were discarded if there was a simultaneous bowel movement and further specimens collected only after rewashing.

The collected specimen was divided into two portions. One was refrigerated and transported to the bacteriological laboratory in a cooled vacuum flask. A maximum of four hours occurred between collection and plating. Quantitative bacteriological culture was carried out as described by Urquhart and Gould (1965). Blood agar and MacConkey plates were inoculated and incubated aerobically for 24 hours. The second portion was examined microscopically within two hours of collection. For staining, 2:7-diaminofluorene phloxine-B was used as described by Prescott and Brodie (1964), thereby allowing differentiation of leucocytes and renal tubular cells. Examination of the uncentrifuged, well-shaken, and stained urine was carried out on an improved Neubauer counting-chamber, counting five squares and multiplying by two (Lawson and Hewstone, 1964).

Results

One hundred and twenty "clean catch" specimens were collected from the 40 babies. A total of 103 specimens (86%) produced on culture a colony count of 10^4 organisms per ml. or less, and 71 of these specimens (59%) produced no growth on culture (Table I). If a level of 10^5 organisms per ml. is

* Paediatric Registrar, Elsie Inglis Maternity Hospital, Edinburgh.

 † Registrar in Bacteriology, Central Microbiological Laboratory, Western General Hospital, Edinburgh.

taken as significant of infection 86% of these specimens could be regarded as showing no evidence of infection.

Table II indicates how the 71 specimens producing no growth on culture were distributed. There were only five babies from whom all three specimens produced growth.

Bacteria were isolated from a total of 49 specimens (41%). The distribution of species and viable count from these 49 was as shown in Table III. For the purpose of this Table, *Staphylococcus albus*, corynebacteria, and *Streptococcus viridans* are regarded as skin commensals, while *Escherichia coli*, non-lactose-fermenting coliforms, *Proteus* species, and enterococci are classed as potential pathogens.

Seventeen specimens produced counts greater than 10^4 organisms per ml. In seven of these skin commensal bacteria were present, suggesting an "unclean" specimen and indicating the necessity for repeating the examination. Ten specimens collected from seven babies produced a high count of potential pathogens in either pure or mixed culture.

10^6	5	2	1	2	0

FIG. 1.—Sex ratio in bacterial counts. FIG. 2.—Cell excretion patterns in first week of life. FIG. 3.—Sex ratio in cell counts.

In one baby two specimens producing no growth on culture were followed by a growth of mixed pathogens to a count of 10^5 organisms per ml. Four babies each produced two specimens with high mixed counts, but the third specimen in each case yielded no growth. In two babies there was growth from all three specimens and a high count of pathogens in one specimen from each. The other specimens from both babies produced smaller counts of pathogens, and in neither baby was the species isolated identical in all three specimens. Progress during the first week of life was normal in both babies, and follow-up was uneventful. Later specimens from these babies repeatedly produced no growth.

As shown in Fig. 1, there was no marked difference in the sex distribution of the colony counts, though there was a tendency for female infants to predominate in the 10^3 to 10^4 and 10^5 organisms per ml. groups.

The pattern of urinary cell excretion in the first week of life is shown in Table IV and Fig. 2. The excretion of squamous cells and leucocytes remained at a low level throughout the first week, average counts of squamous cells ranging from 4.1 to 5.4 /cu. mm., and average counts of leucocytes varying from

TABLE IV.—Differential Urinary Cell Counts in First Week of Life

	Cellular Excretion per cu. mm. in First Week of Life					
	2nd Day		4th Day		6th Day	
	Average	Range	Average	Range	Average	Range
Renal tubular cells ..	14.9	0–40	5.1	0–16	3.0	0–16
Squamous cells ..	5.0	0–36	5.4	0–32	4.1	0–32
Leucocytes ..	0.5	0–46	1.2	0–27	0.8	0–21
Total cells ..	19.5		11.7		7.9	

0.5 to 1.2/cu. mm. The excretion of renal tubular cells shows a very different pattern, falling rapidly from a high average excretion rate of 14.9/cu. mm. on the second day to a low average value of 3 cells/cu. mm. on the sixth day. These cells were easily distinguished from leucocytes by the peroxidase-positive stain.

Ninety-six per cent. of specimens contained fewer than 10 leucocytes per cu. mm. These were collected from 57 males and 51 females. Of the four specimens containing more than 10 leucocytes per cu. mm. two were associated with a high count of mixed organisms suggestive of contamination, and subsequent specimens contained a smaller number of cells. One specimen was associated with dehydration of the newborn, and the fourth specimen, with a high white cell excretion, produced no growth on culture.

There was no correlation of bacterial counts and cell counts in this series. This is shown in Table V, where the apparently high leucocyte count associated with bacterial counts greater than 10^5 /ml. cannot be taken as significant in view of the small number involved (four), including one isolated count of 48 leucocytes per cu. mm. apparently associated with dehydration of the newborn.

The birth history and immediate postnatal progress of the babies were studied in relation to the renal tubular cell count. There were 19 babies showing one or more

counts of more than 10 renal tubular cells per cu. mm. (range 12–40). In 15 of these labour and the postnatal period were uneventful, and in four there was some complication. In the other 21 babies, none of whom produced specimens with high counts of renal tubular cells, there was a history of difficulty in delivery in four and a premature delivery in one.

Only nine (8%) specimens contained more than 10 squamous cells per cu. mm. These were collected from nine babies (six females and three males). While this suggests some sex difference, total numbers are small. No significant sex difference was found in the excretion of renal tubular cells or leucocytes (Fig. 3).

TABLE V.—Relation of Cell Counts to Bacterial Counts

		< 10 ⁵ /ml.	> 10 ⁵ /ml.

Leucocytes	Average	0.8	4.7
	Range	0–22	0–48

Discussion

The possibility of contamination in normally voided urine in the neonate has led to the use of catheterization (Pryles *et al.*, 1961; McCarthy and Pryles, 1963) and suprapubic bladder aspiration (Pryles *et al.*, 1959; Pryles, 1965; Nelson and Peters, 1965; Newman *et al.*, 1967) for the collection of urine specimens for diagnostic purposes. The inherent dangers of both techniques indicated the necessity for the reassessment of the value of clean-catch specimens in this age group. The presence or absence of infection in the urinary tract has been assessed by consideration not only of the viable count but also of the species isolated in three consecutive clean-catch specimens. A viable count of 10⁵ organisms per ml. in a carefully collected midstream specimen is suggestive in the adult of infection in the urinary tract (Kass, 1957). There has been doubt about whether this criterion can apply in the neonate (Nelson and Peters, 1965). Houston (1963) suggested that 10⁶ organisms per ml. or more is abnormal in neonates, but that with counts between 10⁵ and 10⁶ organisms per ml. confirmation of infection is required. In the present series 86% of specimens contained fewer than 10⁵ viable organisms per ml. and 59% produced no growth. This compares favourably with the 31% of specimens producing no growth in the series of McCarthy and Pryles (1963), and is a considerable improvement on series collected by the bag method (Newman *et al.*, 1967).

Urinary cell excretion in the neonate has been the subject of considerable study (Thomson, 1944; Houghton and Pears, 1957; James, 1959; Aas, 1961; Stansfeld, 1962; Lincoln and Winberg, 1964b; Lawson and Hewstone, 1964). In spite of this the number of leucocytes which may be accepted as normal remains in doubt. Lawson and Hewstone (1964) concluded that the finding of more than 10 white blood cells per cu. mm. on two or more occasions is abnormal. Lincoln and Winberg (1964b) fixed the highest acceptable normal number at 25/cu. mm. in males and 50/cu. mm. in females. In this series, with the use of a differential staining technique, 96% of specimens contained fewer than 10 leucocytes per cu. mm.

The high number of renal tubular cells excreted in the first few days of life has been noted by earlier workers (Craig, 1935; Thomson, 1944; Lawson and Hewstone, 1964). The similarity in size and shape of unstained renal tubular cells and leucocytes has in the past made differentiation difficult, but with the peroxidase-positive stain the particular pattern of renal tubular cell excretion emerges.

The high numbers present during the first few days of life have been ascribed to a period of rapid growth and shedding

of cells from the renal tract epithelium at this time of life (Aas, 1961). Hypoxia and renal shut-down have also been suggested as causative factors (Jonsson, 1951; Halvorsen and Aas, 1962). This series produced no evidence to support the latter view.

Conclusions

Normally voided urine can be collected from the newborn without gross contamination by a careful clean-catch technique. When three specimens are collected from one patient contamination rather than infection is suggested by variation in the number and species of organisms isolated from specimen to specimen. Viable counts of less than 10⁵ organisms per ml. are usually due to contamination. Higher counts may also be due to contamination, and the presence of infection should be suspected only when counts of 10⁵ organisms per ml. or more of the same species are isolated in at least two consecutive specimens. This procedure is time-consuming, and personal supervision is essential, but it is without hazard to the infant. Only when every effort has been made to reach a conclusive diagnosis on the results of specimens collected in this way should other methods of urine collection be contemplated.

The newborn infant excretes a large number of renal tubular cells which may be confused with leucocytes if a differential stain is not used. The number of renal tubular cells excreted falls rapidly during the first week of life, while the excretion of leucocytes and squamous cells remains relatively constant. Leucocyte counts up to 10/cu. mm. can be accepted as normal in both sexes.

The value of using a simple differential stain, as described above, when carrying out microscopical examination of the urine is emphasized.

Summary

Three specimens of urine were collected from each of 40 babies on the second, fourth, and sixth day of life. A clean-catch technique was employed and shown to be a reliable method of urine sampling.

The cell excretion pattern during the first week of life was studied. Ninety-six per cent. of specimens contained fewer than 10 leucocytes per cu. mm. A high rate of excretion of renal tubular cells was observed during the first few days of life.

We would like to thank Professor J. O. Forfar and Dr. J. C. Gould for their helpful criticism and encouragement. Also we would like to acknowledge the co-operation of the nursery nursing staff at the Elsie Inglis Maternity Hospital, Edinburgh.

Haemoglobin Concentration and Other Values in Women Using an Intrauterine Device or Taking Corticosteroid Contraceptive Pills

J. ALAGHBAND ZADEH,* L.M.S.S.A.; C. D. KARABUS,† M.B., M.MED.(PAED.), M.R.C.P.
J. FIELDING,‡ M.R.C.P., F.C.PATH.

Brit. med. J., 1967, 4, 708-711

Surveys have shown that 20-25% of women in this country have iron-deficiency anaemia with haemoglobin concentrations less than 12 g./100 ml. (Davidson *et al.*, 1943; Kilpatrick and Hardisty, 1961). In addition, about 30% of apparently normal women with haemoglobin above 12 g./100 ml. have been shown to be sideropenic (Fielding *et al.*, 1965; de Leeuw *et al.*, 1966.)

Two of the newer methods of contraception now being widely adopted—the intrauterine device and oral corticosteroid contraceptive pills—are both said from subjective observation to alter menstrual blood loss: the intrauterine device to increase it, the oral corticosteroids to diminish it. In neither case have these changes been quantitated. However, iron balance in adult women is so precarious that changes in blood loss are likely to lead to changes in the incidence and severity of iron deficiency.

The present paper reports a pilot survey of 219 women attending a Family Planning Association clinic. We find that the continued use of an intrauterine device leads to a significant fall in the mean haemoglobin concentration and to an increase in the incidence of anaemia. The steroid contraceptive pill of "combined" formulation leads to an increase in the concentration of haemoglobin, but the results suggest that the effect may be a complex one.

Methods and Clinical Material

A total of 294 women attending a Family Planning Association clinic were investigated. Seventy-five have been excluded from the analysis. These consisted of blood donors, women who had been pregnant or who had received iron therapy within the previous six months, those who attended for gynaecological abnormalities, a small number who were using other mechanical methods of contraception, and those who had previously used an intrauterine device and who were now taking oral contraceptives or vice versa. Also among those excluded were 13 women who were taking oral contraceptive pills with a sequential formulation, since they were too few for statistical analysis.

The remaining 219 women are divided into three groups: (1) a control group of 53 women who were attending the clinic for the first time; (2) 72 who had been fitted with an intrauterine contraceptive device, almost all of the Lippes loop type; and (3) 94 who had been taking oral contraceptive pills with a combined formulation of various types, which included Anovlar, Gynovlar, Lyndiol, Ortho-Novin, Ovulen, and Ovrin.

A venous sample was taken from each patient by a standard technique to ensure minimal venous stasis. Haemoglobin was estimated in duplicate by the cyanmethaemoglobin method, the packed cell volume (P.C.V.) in duplicate by a microhaematocrit method, and the mean corpuscular haemoglobin concentration (M.C.H.C.) was calculated from these observations.

The validity of considering women who were attending the clinic for the first time as a control group was ascertained, after

the investigation had been completed, by dividing these into two groups according to the method of contraception subsequently advised by the medical staff of the clinic. Since the type of contraceptive advice depended on clinical observations, differences in age group and parity were expected between the groups assigned to contraceptive pills or to intrauterine device. Table I shows that the intrauterine device is advised for women of higher age group and greater parity than those given the contraceptive pill. Nevertheless, there are no haematological differences between the two subgroups, and therefore the use of the combined group of 53 women appears to be a valid control for the haematological values investigated.

TABLE I.—53 Women Attending Clinic for the First Time. Means $\pm$ Standard Error

	No.	Age (Years)	Parity	Haemoglobin (g./100 ml.)	P.C.V. (%)	M.C.H.C. (%)
Control group	53	27.8 $\pm$ 0.81	1.7 $\pm$ 0.21	13.4 $\pm$ 0.11	40.2 $\pm$ 0.26	33.4 $\pm$ 0.17
Assigned to I.U.D. ..	32	30.3 $\pm$ 0.97	2.2 $\pm$ 0.20	13.4 $\pm$ 0.15	39.9 $\pm$ 0.47	33.5 $\pm$ 0.20
Assigned to C.P. ..	21	23.9 $\pm$ 0.90	0.8 $\pm$ 0.35	13.5 $\pm$ 0.15	40.5 $\pm$ 0.33	33.3 $\pm$ 0.32
Student's <i>t</i> ..		<i>P</i> < 0.001	<i>P</i> < 0.001	<i>P</i> > 0.5	<i>P</i> > 0.9	<i>P</i> > 0.9

I.U.D. = Intrauterine device. C.P. = Contraceptive pill.

It should be stressed here that in this survey only one investigation was made in each subject. The control group and the groups on contraceptives for varying periods of time consisted of different women. Mean values are given in the results with their standard errors.

Effect of Intrauterine Contraceptive Device

Age and parity in this group were similar to those of the control subgroup subsequently assigned to the intrauterine device. Their mean haemoglobin concentration was 12.8 $\pm$ 0.12 g./100 ml. compared with 13.4 $\pm$ 0.11 g. in the controls (*P* < 0.01). The packed cell volume also showed a significant decrease (*P* < 0.001); the M.C.H.C. in the group as a whole was less than that in the control women but failed to reach significant levels of difference. Table II summarizes these results.

The three values decreased progressively up to 12 months of use. The fall in M.C.H.C. followed later than that in the haemoglobin and was significantly reduced after 7 to 12 months' use. Later the trend appears to reverse, with a general increase

of them were below 13 g./100 ml. (Fig. 1). The proportion of women with haemoglobin concentration 'outside these limits is significantly different in the intrauterine device group than among the controls (Table III). The deterioration in haematological status is also apparent in the distribution of M.C.H.C.; it is bimodal in the control group, but changes to a single distribution around the lower mode after 7 to 24 months' use (Fig. 2).

FIG. 1.—Intrauterine device. Proportion of women with haemoglobin concentration above 14 g. and below 13 g./100 ml. after varying periods of time. 0=Control group.

FIG. 2.—Intrauterine device. Scattergram of M.C.H.C. in controls and in women using an intrauterine device.

Effect of Contraceptive Pills

The age and parity of women taking contraceptive pills are similar to those of the subgroup of the controls subsequently advised to take the pill as their method of contraception. Table IV summarizes the findings. Haemoglobin values increase from a mean of 13.4 ± 0.11 g./100 ml. in the controls to 13.7 ± 0.10 g., but this increase fails to reach accepted levels of significance

($0.05 < P < 0.1$). The increase in P.C.V., however, is significant at the 1/50 level. There were no significant changes in the M.C.H.C.

TABLE IV.—Haemoglobin, P.C.V., and M.C.H.C. in Women Taking Contraceptive Corticosteroids. Means $\pm$ Standard Error

	No.	Haemoglobin (g./100 ml.)	P.C.V. %	M.C.H.C. (%)
Control group	53	13.4 ± 0.11	40.2 ± 0.26	33.4 ± 0.17
Contraceptive pill:				
After 1-6 months	31	13.7 ± 0.19	41.1 ± 0.68	33.3 ± 0.27
" 7-12 "	22	13.8 ± 0.19	41.1 ± 0.39	33.7 ± 0.35
" 13-24 "	19	13.5 ± 0.20	41.3 ± 0.48	32.8 ± 0.43
" > 24 "	22	13.7 ± 0.20	41.0 ± 0.41	33.4 ± 0.27
Total	94	$13.7 \pm 0.10^*$	$41.1 \pm 0.21^\dagger$	33.3 ± 0.16

Student's *t* compared with control: * $0.5 < P < 0.1$; $^\dagger P < 0.02$.

The rise in haemoglobin and P.C.V. occurs mainly in the first six months, with little change thereafter. These trends are emphasized by considering the proportion of women with haemoglobin concentration above 14 g. and below 13 g./100 ml. (Fig. 3). After taking contraceptive pills for one to six months and also after 7 to 12 months the proportion of women with haemoglobin above 14 g./100 ml. is increased compared with the control group ($P < 0.01$). Thereafter the differences are not significant.

FIG. 3.—Contraceptive pills. Proportion of women with haemoglobin above 14 g. and below 13 g./100 ml. after varying periods of time.

However, though the increase in the proportion of women in the higher haemoglobin ranges is well marked, no changes were found in the proportion with haemoglobin levels below 13 g./100 ml. (Table V). This anomalous finding is discussed below.

TABLE V.—Haemoglobin Concentration

	No.	More than 14 g./100 ml.		Less than 13 g./100 ml.	
		No.	%	No.	%

Student's <i>t</i>		$P < 0.01$		$P > 0.8$	

Discussion

Intrauterine Device

It is evident from this survey that the intrauterine contraceptive device increases menstrual loss markedly, and affects the haematological status of women using it. Our results show a fall in haemoglobin values from a mean of 13.4 g./100 ml. to 12.8 g./100 ml. after 7 to 12 months' use. Perhaps more striking is the observation that after 7 to 12 months none of these women had haemoglobin concentrations above 14 g./100 ml., compared with about 19% in the control group; whereas 60%

had haemoglobin levels below 13 g./100 ml. compared with about 20% in the control group.

The fall in haemoglobin values is in general paralleled by a lesser fall in the haematocrit, as is usual in iron-deficiency anaemia, resulting in a decreasing M.C.H.C. It is interesting to note that the distribution of M.C.H.C. in the control group is bimodal, whereas this is replaced by a single mode at the lower level in women using the intrauterine device. It may be permissible to conclude that after 7 to 12 months' use the majority of women are suffering from varying degrees of iron-deficiency anaemia.

There appears to be a trend towards improvement after the intrauterine device has been used for more than a year. This may indicate that blood loss gradually returns to more normal values. However, it is more likely to mean a selection of cases during this time, since a study of the clinic records showed that about 25% of women fitted with an intrauterine device were no longer using it after two years.

The effect of such an increase in menstrual loss would not be experienced uniformly among all women. Those who began without anaemia would probably augment the intestinal absorption of iron and thus compensate in part for the effect of the increased loss; those who were already iron-depleted are also likely to be at the limit of their iron-absorption capability and would suffer a greater fall in haemoglobin for a given increase in loss. Thus the effect of the intrauterine device is relatively more severe in those who are already anaemic or iron-depleted.

This marked effect in inducing iron deficiency should be considered when giving contraceptive advice, and certainly in a programme of population control in less-developed countries.

Contraceptive Pill

Clinical observations on the reduction of menstrual loss in women taking oral contraceptives of combined formulation had prompted a search for possible changes in haematological status. Burton (1967) found a significant increase in haematocrit, and an increase in haemoglobin concentration which failed to reach 1/20 significant level. In our larger series we, too, have found a significant increase in haematocrit and an increase in mean haemoglobin concentration which we have analysed in greater detail. We observed no differences in the M.C.H.C.

The changes are more clearly demonstrated by considering the proportion of women with haemoglobin above 14 g./100 ml. and those below 13 g./100 ml. Of those taking contraceptive pills 40% had haemoglobin concentrations above 14 g./100 ml. compared with 19% in the control group ($0.001 < P < 0.01$). This increase in the proportion of haemoglobin concentration in the higher range seems to occur quite soon: after 1 to 6 months it was 42%, and at 7 to 12 months it was 50%.

It might be expected that an increase in haemoglobin concentration which resulted from diminished blood loss would be more readily detected in the range below 13 g./100 ml., which presumably includes minor degrees of anaemia, than in the higher range. We found, however, that the proportion of women with haemoglobin below 13 g./100 ml. did not appear to change significantly at any time up to two years compared with the control group. This anomalous finding suggests that the observed increase in haemoglobin concentration and in haematocrit is not due to a single factor, such as a diminution in blood loss, operating uniformly in all women.

The group taking pills were heterogeneous from several points of view. They varied, for instance, by age and parity. It is possible that, though haematologically similar before starting the pill, these differences might be correlated with differing responses to corticosteroids. We found, however, that there were no differences based on age or parity.

In all, six types of combined formulation of pill were used. We compared the effect of pills containing the progestogen norethisterone acetate with others and found a significant differ-

ence between the groups (Fig. 4). Furthermore, the difference between the mean haemoglobin concentration of women taking this progestogen was 13.8 g./100 ml. and reached significant levels of difference from the control group ($0.025 < P < 0.05$). Nevertheless, in this subgroup of pills containing norethisterone acetate, as in the pill group as a whole, the effect on haemoglobin concentration is more pronounced in the higher than in the lower ranges.

FIG. 4.—Contraceptive pills. Proportion of women with haemoglobin above 14 g. and below 13 g./100 ml. NethA=Pills containing norethisterone acetate.

We may only speculate at this stage on the significance of this finding. Haemoglobin mass may vary at differing rates from plasma volume. In pregnancy, to which the hormone status of "taking the pill" is most often compared, plasma volume increases relatively more than red cell mass and contributes to the fall in haemoglobin concentration seen in pregnancy. However, steroid status in pregnancy differs considerably from the use of the contraceptive pill, and there is no reason to expect similar haemodynamic changes. For instance, Burton (1967) shows that serum iron increases with the pill, whereas it falls in pregnancy; furthermore, some anabolic corticosteroids have been shown to produce haemoconcentration (Verwilghen *et al.*, 1966). A relative reduction in plasma volume occurring in some women, but not in others, might account for the uneven increase in haemoglobin concentration. Should haemoconcentration indeed be one of the effects of some combined formulations, the resulting increase in blood viscosity may have a bearing on the problem of thrombotic phenomena. Lastly, it is possible that hyperplasia of the marrow may occur as a result of corticosteroid stimulation, similar to the well-known hyperplasia seen in pregnancy.

Though we show an increase in haemoglobin concentration and in haematocrit in women taking oral contraceptives, the effect is irregularly distributed and we cannot be certain that the increase is due solely to diminished blood loss.

Summary

Haemoglobin concentration, P.C.V., and M.C.H.C. were estimated in 219 women attending a Family Planning Association clinic. In the control group of 53 women attending the clinic for the first time there was no difference in haematological status between those subsequently fitted with an intrauterine device and those advised to take the contraceptive pill.

Among 72 women who had been using an intrauterine device there was a progressive fall in mean haemoglobin concentration up to one year of use ($P < 0.001$). After 7 to 12 months' use none of these women had haemoglobin concentrations above 14 g./100 ml., while in 60% it was less than 13 g./100 ml. The changes in M.C.H.C. indicated that virtually all were iron-deficient after seven months' use.

In 94 women taking oral contraceptive pills of combined formulation the mean haemoglobin concentration was 13.7 ± 0.10 g./100 ml. compared with 13.4 ± 0.11 g. in the controls. The mean P.C.V. increased from 40.2 to 41.1 ($P < 0.02$). There were no changes in the M.C.H.C.

Forty per cent. of women taking the pills had haemoglobin concentrations greater than 14 g./100 ml. compared with 19%

in the control group. The increase in haemoglobin in the higher ranges occurred mainly in the first six months of use. In the range below 13 g./100 ml. there were no differences from the control group. Some formulations, especially those containing norethisterone acetate as progestogen have greater effect than others in raising haemoglobin concentrations.

Diminished blood loss alone does not account for all the changes observed. Haemoconcentration may occur in some subjects; if this is so the resulting increased viscosity may have some bearing on thrombotic phenomena. A further possible explanation is corticosteroid stimulation of bone-marrow activity.

We wish to thank the Managing Committee of the Family Planning Association, Dr. Hilary Hill, and Dr. Mary Pollock for

their helpful co-operation. The work was supported by grants from the Medical Research Council and the North-west Metropolitan Regional Hospital Board. Requests for reprints should be made to J. Fielding.

Psychiatric Study of a Consecutive Series of 19 Patients with Regional Ileitis*

FRED FELDMAN, M.D.; DAVID CANTOR, M.D.; SIDNEY SOLL, M.D.; WILLIAM BACHRACH, M.D.

Brit. med. J., 1967, **4**, 711-714

This paper reports a study of psychiatric factors in regional ileitis. The study parallels a similar survey (Feldman *et al.*, 1967) in which we reported a series of 34 unselected cases of ulcerative colitis. In the latter inquiry a disease regarded by many psychiatrists as an unimpeachably psychosomatic illness was found to have probably no essential emotional causation.

Regional ileitis, a disease of obscure origin, has not attained the same almost classical reputation of ulcerative colitis as a psychosomatic illness. Nevertheless, since 1935 a number of authors have expressed the opinion that regional ileitis is a psychosomatic disease. A leading American textbook (Beeson and McDermott, 1967) stated: "It is thought that the repeated impact of emotional stress may give rise to dysfunction of the small intestine, with subsequent structural changes. This is supported by the clinical observation that recurrent symptoms are, at times, chronologically related to disturbing psychologic events."

Relation between Regional Ileitis and Ulcerative Colitis

The question is still open whether regional ileitis is actually a separate pathological entity from ulcerative colitis. Many physicians—for example, Eisenstadt (1965a), Ross (1965), and Crohn (1965)—say they are but different manifestations of the same disease. If this is true, then why has there been such prominence given to the notion of ulcerative colitis as a psychosomatic disease compared with the lesser emphasis on regional ileitis? The question is still very controversial. However, evidence for suspecting that there is a strong relation between the two diseases is found in: (1) their beyond-chance genetic coincidence (Crohn and Yarnis, 1958; Sherlock *et al.*, 1963; Edwards and Truelove, 1964; McConnell, 1965); (2) the association of both diseases with ankylosing spondylitis (McBride *et al.*, 1963; McConnell, 1965; Acheson, 1965); (3) immunological studies (Phear, 1958; Taylor, 1965; Acheson, 1965); (4) the higher risk in Jews, of approximately the same order of magnitude for both diseases (Acheson, 1960; Acheson and Nefzger, 1963); (5) a number of cases where the condition of the colon suggested

that both diseases were present (Lumb, 1951; Porritt and Hunt, 1960); (6) the occurrence of the same complications, including erythema nodosum, pyoderma gangrenosum, arthritis, uveitis, and conjunctivitis; and (7) the many overlapping clinical features of the diseases, so that one is sometimes misdiagnosed for the other (Cooke and Brooke, 1955; Yarnis, 1955; Hendrix, 1964).

In our small series of 19 cases a number of the foregoing features were present. (1) Genetic coincidence: a 47-year-old man with onset of regional ileitis at 19 had a brother who had ulcerative colitis at 16 and a sister who had ulcerative colitis at 40. (2) Ankylosing spondylitis: one of our patients had ankylosing spondylitis preceding the onset of regional ileitis. (3) Higher risk in Jews: 10 of the 19 patients were Jews, a higher proportion than would have been expected from the wide referral area. (4) Complications: a 19-year-old girl had erythema nodosum. (5) Overlapping clinical features: three cases were first diagnosed as ulcerative colitis, and several months of careful study were required to confirm the correct diagnosis of regional ileitis.

Validation of Psychosomatic Disease

The term "psychosomatic disease" has gone somewhat out of vogue during the past few years. It is now more fashionable to speak of "multifactorially-caused diseases" in referring to illness of undetermined origin. Nevertheless, if one of the components of an illness is psychosomatic, then an emotional cause of some type must be presumed to exist, or the disease cannot occur. In our study of ulcerative colitis we set up a catalogue of criteria for validating whether one essential component of a disease's cause was psychogenic. The same criteria have been examined for evidence of a psychogenic factor in regional ileitis. The seven criteria are: (1) a characteristic personality disorder or other serious psychiatric illness; (2) a clear emotional precipitating factor chronologically related to the illness; (3) general, conscious stress; (4) basic emotional problems of long duration (unconscious stress); (5) alternation of symptoms, or syndrome shift; (6) characteristic patterns of illness in the life history; and (7) efficacy of psychotherapy.

* From the Department of Psychiatry and Department of Medicine, Cedars-Sinai Medical Center, Mount Sinai Division, Los Angeles, California.

Material and Method

Nineteen patients with regional ileitis were studied, constituting every known patient with regional ileitis admitted to the Mount Sinai Hospital between August 1964 and June 1967. Tables I and II list age, sex, severity of disease, length of illness, area of involvement, patients requiring surgery, and complications. Two types of control groups were used. The first was a control group only in the loosest sense, since it consisted of the general population, divided into normal and abnormal according to arbitrary criteria. The second control group comprised the first 74 consecutive patients admitted to the gastroenterology service while the study on regional ileitis was in process. No patients with disease of the large intestine were included.

TABLE I.—Age Groups and Sex Distribution of 19 Regional Ileitis Patients

Age Group (At Time of Onset)	Males	Females	Total
10-20	8	2	10
21-30	1	3	4
31-40	1	1	2
41-50	—	1	1
51-60	—	1	1
61-70	—	1	1

TABLE II.—Other Clinical Data on 19 Regional Ileitis Patients

Severity of disease	Mild	0
	Moderate	4
	Severe	15
Average length of illness in years	Moderate disease	3
	Severe disease	9
Area of involvement	Ileum alone	10
	Ileum and colon	9
Patients requiring surgery		9
Complications	Rheumatoid spondylitis	1
	Erythema nodosum	1

The team members were essentially those who conducted the concurrent study on ulcerative colitis, and consisted of a psychiatrist, physician, and two gastroenterologists. Each patient had two standard psychiatric interviews by the team, of the free-association type, but eventually including a discussion of sufficient current and past material to yield data for scoring 65 variables regarded as salient for personality evaluation (Table III). Subsequently the team saw the patient as often as possible during his hospital stay. Each patient was designated as "normal" or "abnormal" in each of the 65 categories of the protocol. Normal was scored as 3, 4, or 5; abnormal as 1 or 2. A normal distribution curve was used (Fig. 1). The curve

FIG. 1.—Normal distribution curve.

refers to the general population—that is, an arbitrary assumption was made that approximately 70% of the general population was "normal" and 30% definitely "abnormal." It may be noted that four recent large epidemiological studies of psychiatric illness in general populations have confirmed the approximate correctness of this original guess at the distribution of "normality" (Essen-Möller, 1956; Srole *et al.*, 1962; Leighton *et al.*, 1963; Bahn *et al.*, 1967).

Results

Personality Types and Psychiatric Illness.—Seventeen of the 19 patients were regarded as essentially "normal" within the limits we have described, and two were "abnormal." The two abnormal patients were a compulsive and somewhat impulsive man of 30 and an impulsive, somewhat eccentric, adventurous woman of 32. Both, however, had many ego strengths. Neither was psychotic. The other 17 patients were eight diagnosed as normal passive personality types and nine as normal aggressive types. There were no other significant psychiatric diagnoses, except in the 68-year-old woman who had moderate phobias 10 years before the onset of the regional ileitis.

Precipitating Factors and Chronological Relations.—There were no cases where a significant precipitating factor was

thought to have occurred close in time to the onset of regional ileitis. In two instances there appeared to be significant stress at the time of relapses. However, the total number of "attacks," "relapses," or "exacerbations" was quite high (probably numbering 40 or more for the 19 patients), and the figure of two, associated with stress, would therefore appear small. There were no instances of extreme separation anxiety at the time of either onset or relapse, and no instances where a fear of taking forward steps in career, education, or marriage seemed crucial.

General Conscious Stress, Perhaps Cumulative.—In one case there was the possibility of long stress, associated with work, before relapses. Onset of the illness, however, had occurred 10 years previously, when the patient was in college. Moreover, he enjoyed his work, and ranked very high in professional capacity and conscientiousness. There were four other cases in which moderate stress was present before a relapse.

Basic or Nuclear Emotional Problems, with Significant Background Features, Symbolically Related to the Illness (Unconscious Stress).—There were six cases in which the total background or dynamic factors were of some significance, but none was extreme. It was felt that none of the patients had had nuclear conflicts in his earlier years that were definitely expressing themselves symbolically in the form of the somatic illness.

Alternation of Symptoms, or Syndrome Shift.—No true alternation of either psychiatric or physical symptoms with the regional ileitis was encountered in the history or hospital course of the patients. There was one instance of rheumatoid spondylitis, which had begun before the ileitis but did not alternate with it. Moderate depression was present in four cases but was linked to the severity of the illness.

Characteristic Patterns of Illness in the Life History.—There was no significant hypochondriasis, even in the two "abnormal" patients. There was no history of preoccupation with bowel habits.

Efficacy of Psychotherapy.—Five patients had had psychotherapy ranging from one month to one and one half years. It had effected no improvement in the regional ileitis itself in any case.

Results in Control Group

The results in the 74 control patients are not described in detail here, but are compared with the regional patients in Fig. 2. In general, the control patients showed as much psychopathology as, or more than, the regional ileitis cases.

Discussion

Regional ileitis has been arraigned as a psychosomatic disease by a number of psychiatric investigators and denied as one by

FIG. 2.—Comparison of frequency of occurrence of the mentioned psychiatric factors between 19 regional ileitis and 74 control patients.

a few. Gastroenterologists generally have avoided a definite statement about the role of emotions. Some, including Crohn himself (Crohn and Yarnis, 1958), have stated that there is no support for the psychosomatic concept. No studies and no statements have been sufficiently definitive to give physicians a firm foundation for their thinking. We found that many of our patients had been told by one or more physicians that emotional tension might be the cause of their illness. One of the patients, a busy surgeon, had been advised by several physicians to change his specialty to some field of medicine where there would be "little tension."

The psychiatric literature is remarkably scanty—approximately 13 studies in 30 years. So limited and contradictory a literature, to make even the impact it has on medical education, must have derived from other sources. The unavoidable association with ulcerative colitis has prevailed to some extent, and the unconscious need to divine magical answers for diseases of unknown cause has played a part. Arieti (1959) states that "regional ileitis and ulcerative colitis are conditions involving tissue breakdown that are, at least in part, determined by emotional problems." Kaelbling and Patterson (1966) assert that "importance is attached to the significance of emotional factors in regional ileitis."

The studies by psychiatrists are subject to the following criticisms: (1) they sometimes dealt with very few patients, studied at great length; (2) there were no unselected consecutive series; (3) some were retrospective studies; (4) patients were often only those selected by other physicians for referral to psychiatrists because of concurrent but not necessarily associated emotional problems; and (5) the criteria for emotional evaluation were usually not given in detail.

The studies by psychiatrists who favoured the psychosomatic explanation included series of seven patients (Stewart, 1949), 11 patients (Paulley, 1948), four patients (Grace, 1953), one patient (Sperling, 1960), and two patients (Mersereau, 1963). Two psychiatric studies objecting to the psychosomatic hypothesis were those involving eight patients (Kraft and Ardali, 1964) and 16 patients (Crocket, 1952). The latter was the only series approaching ours in size, and was carefully done, but the material was not consecutive or unselected.

The reports by gastroenterologists referring to psychiatric causation were impressionistic, and no rigorous psychiatric evaluations were carried out. Reports favouring the psychosomatic hypothesis somewhat vaguely were those of 40 cases (Dashiell *et al.*, 1951), 20 cases (Richman, 1955), 34 cases (Armitage and Wilson, 1950), 33 cases (Hunt, 1965), and no definite number of cases (Schepers, 1945; Eisenstadt, 1965b).

In contrast to the papers noted above there are many hundreds by gastroenterologists, who reported much longer series of cases, including collections of 700 patients (Crohn and Yarnis, 1958), 600 patients (Van Patter *et al.*, 1954), 500 patients (Turner, 1953), and other large series (Strömbeck, 1937; Warren and Miller, 1942; Tallroth, 1943; Janowitz, 1955). In these studies, and in many others reviewed, either no reference was made to psychiatric factors or they were thought to be minimal or insignificant. The impression gained is that gastroenterologists regard their patients as no different from any other seriously ill patients.

Summary and Conclusions

Nineteen consecutive unselected cases of regional ileitis were studied psychiatrically. No evidence was found that an emotional factor was a significant aetiological component. Seventeen of the 19 patients were regarded as "normal." The results of a study such as this are qualified by questions concerning the concept of normality; our recognition that the assumption of 70% normality in the general population is open to criticism; the reliability of diagnostic criteria in psychiatry; the difficulty of assessing deeper problems with brief interviews;

and the central problem of whether primary psychosomatic disease exists. Nevertheless the significant emotional factors relating to psychosomatic illness noted in the literature were investigated and found not to apply to any important degree. We do, therefore, raise the question whether the disease should be regarded as psychosomatic in any way.

Evaluation of a Screening Survey for Anaemia in Adult Non-pregnant Women

WITH THE ASSISTANCE OF E. H. EVANS,‡ M.D., M.R.C.P., J. DE SWIET,‡ M.D., M.R.C.P., AND J. V. WILLIAMS,‡ M.D., M.R.C.P.

Brit. med. J., 1967, 4, 714-717

Considerable interest has been shown recently in community health screening (Backett, 1960; Wilson, 1963; Acheson, 1963; Horne, Clark, and Patterson, 1967). The value of any health-screening procedure depends both on the proportion of persons detected with the disease (or diseases) being sought, or with treatable associated conditions, and on the importance to life or health of these conditions. The number of affected persons detected is dependent both on the prevalence of the disease, or the conditions associated with it, in the community to which screening is offered, and on the nature and extent of selection, if any, of those members of that community who co-operate. In fact very little is known about the selection of persons who readily co-operate in health-screening procedures except in a very few situations, such as mass miniature radiography (Brad-

bury, 1948) and cervical cytology (Wakefield and Barić, 1965), in both of which it seems that affected individuals are, on average, less likely to co-operate than those who are unaffected, though in coal-workers' pneumoconiosis (Cochrane, 1951) and possibly in other compensatable industrial diseases the reverse is probably true. Other than in a few such cases very little is known about how persons who spontaneously attend community screening clinics differ from other members of the community.

Assessment of the importance of the conditions detected during a screening survey necessitates value judgements which are not easily made and which ideally should be based on data relating to changes in the subsequent mortality or morbidity in the community screened. In the haematological community study described here the initial survey was evaluated as an ad hoc health-screening procedure. This evaluation was based on the following: (1) the proportion of subjects seen who were thought to be "anaemic," (2) the symptomatic benefit which resulted from iron therapy in these subjects, and (3) the pre-

*From the Epidemiological Research Unit of the Medical Research Council, Cardiff.

†External Staff, Medical Research Council, Llandough Hospital, Penarth.

‡Physicians, Llwynypia Hospital, Rhondda.

valence of serious underlying conditions detected in subjects believed to be anaemic.

In addition, the opportunity was taken to study some aspects of the selection of subjects who spontaneously attend a community health-screening survey. This was based on comparisons of the distributions of certain haematological and other variates, including symptomatology, in almost all the adult women in the geographically defined area selected for the survey with the same data in a large group of women of the same age who lived in immediately adjacent areas and who, without being contacted by the survey team, spontaneously attended the survey clinic.

The screening survey on which this report is based was confined to adult women. It was conducted as one of a series of studies of epidemiological aspects of iron deficiency. These studies included an examination of the symptoms associated with low haemoglobin levels and the effect of iron therapy on symptoms; an examination of the symptomatic benefit of iron therapy in women with "normal" haemoglobin levels who complained of excessive fatigue; an evaluation of the part played in iron deficiency by dietary intake and menstrual loss of iron; and studies relevant to the prevention of iron deficiency in the community.

Method

An area in the Rhondda Fawr, an industrial valley in South Wales, was defined, and all female residents aged 20 to 64 years (inclusive) were visited and invited to attend a clinic. At the clinic a questionnaire was administered which covered certain aspects of symptomatology and general health, and the number of visits paid to a general practitioner during several intervals before the survey. Measurements were made of height, weight, triceps skin-fold thickness, and one simple aspect of lung function (the peak expiratory flow rate, as recorded on a Wright Peak Flow Meter). A sample of venous blood was taken for estimations of haemoglobin level and packed cell volume, and, in those found to have a haemoglobin level below 12 G., a blood film was examined. Haemoglobin level was estimated as cyanmethaemoglobin, and is expressed here as G. (grammes of haemoglobin per 100 ml. of blood). Packed cell volume (P.C.V.) was estimated by a microhaematocrit method.

On leaving the clinic a self-administered questionnaire was given to each woman, together with a stamped addressed envelope for its return. This was a modified version of the one described by Wood and Elwood (1966), and enabled six of the symptoms commonly attributed to iron-deficiency anaemia to be graded on seven point scales. In addition, this questionnaire contained two series of 10 questions in random order. One series related to symptoms or signs commonly believed to occur in iron-deficiency anaemia; the other 10 were similar to questions in the Cornell Medical Index which have been used in community studies of psychoneurosis by Rawnsley (1966), Abramson, Terespolsky, Brook, and Kark (1965), and others. These latter questions were used here to give a measure of psychoneurosis in each subject.

The general practitioners in the area were visited, and with their permission all women with haemoglobin levels below 10 G. who were not already on treatment were offered referral to a local hospital outpatient clinic for examination and investigation by a consultant physician. The women with haemoglobin levels between 10 and 12 G. who were not already on treatment were questioned in a conventional clinical interview about symptoms which might indicate serious underlying disease, and then, together with those with levels below 10 G., were screened for occult blood in three faecal specimens by Hematest. In an attempt to evaluate the relevance of these results to anaemia a representative sample of an almost equal number of women with haemoglobin level of 12 G. and above were also screened in the same way for occult blood.

Women with haemoglobin levels between 8 and 12 G. who were not already on treatment were admitted to a clinical trial of the effects on symptoms of iron therapy (200 mg. of elemental iron as ferrous carbonate in Ferrodic per person per day for eight weeks). This study was very similar to the one described by Elwood and Wood (1966), and detailed results will be published elsewhere. Only data from this trial which are relevant to the evaluation of the basic screening survey are referred to here.

In an attempt to ascertain factors which might be relevant to the selection of persons who spontaneously attend a community health survey clinic comparisons were made between the distributions in the basic population and the spontaneous attenders (these groups are defined below) of a large number of attributes and variates, including age, parity, haemoglobin level and P.C.V., height, weight, skin-fold thickness, symptoms (including the neurotic grade described above), and estimates of the number of visits paid to a general practitioner during one week, one month, and one year immediately before the survey.

Results

During the survey 1,138 women were seen. Nine hundred and twenty were residents in the defined area and were aged 20–64 years; 19 of these were pregnant and are omitted from all subsequent discussion. The others are subsequently referred to here as "the basic population." The remaining 218 women seen were either outside the age limits of the study or were residents in surrounding areas who were not visited or contacted in any way by the survey team but heard about the survey and attended the survey clinic spontaneously. The 180 of these who were aged 20–64 years are subsequently referred to here as "the spontaneous attenders." Those who were outside 20–64 years of age have been excluded from all that follows. Table I summarizes all these data and incidentally shows some evidence of a relative deficiency of women in the younger age groups, probably due to migration out of the area.

TABLE I.—Distributions by Age of Basic Population and Spontaneous Attenders

Age	Basic Population			Spontaneous Attenders
	Total	Seen	Refused	
15–	—	—	—	18
20–	66	64 (11)	2 (3.0%)	13
	81	77 (1)	4 (4.9%)	11
30–	110	102 (4)	8 (7.3%)	26
	140	128 (1)	12 (8.6%)	24
40–	143	132 (2)	11 (7.7%)	30
	114	107	7 (6.1%)	24
50–	105	96	9 (8.6%)	20
	118	105	13 (11.0%)	25
60–	128	109	19 (14.8%)	7
65+	—	—	—	20
Total	1,005	920 (19)	85 (8.5%)	218

Women outside age limits of study (20–64 years) together with those who were pregnant (shown in parentheses) omitted from χ^2 tests and all subsequent discussion. Basic population seen and spontaneous attenders: $\chi^2 = 13.28$. D.F. = 8: $0.2 > P > 0.1$.

Basic population seen and refusals: $\chi^2 = 12.46$, D.F. = 7: $0.1 > P > 0.05$.

The distributions of the basic population and the spontaneous attenders by haemoglobin level and P.C.V. are shown in Table II. There is no evidence of a significant difference (at $P < 0.05$, the criterion of significance used throughout) in the distributions of these variates in the two populations. No case of megaloblastic anaemia was detected.

There were 31 (3.4%) women in the basic population and 13 (7.2%) in the spontaneous attenders who had haemoglobin levels below 10 G. These proportions do not differ significantly. Thirty-seven of these were not already under treatment for anaemia, and agreed to referral to hospital outpatient departments for further examination and investigation. In nine cases (0.8% of all the women) further action relevant to the iron-deficiency anaemia was taken. One woman had haemorrhoids injected, six had uterine dilatation and curettage, one who could

not tolerate oral iron was admitted to hospital for blood transfusion, and one was found on routine x-ray examination to have an opacity in her chest, which was removed and found to be a carcinoid adenoma.

* Several estimations inadvertently omitted.

The 63 women in the basic population and the 13 of the spontaneous attenders who had haemoglobin levels between 10 and 12 G. were visited in their homes and questioned in a conventional clinical interview. In a very few cases symptoms were elicited that were suggestive of underlying conditions (such as haemorrhoids, etc.), but in no case in which these symptoms might have been relevant to the iron-deficiency anaemia were they thought to be severe enough to warrant the initiation of further investigations.

There were 120 women with haemoglobin levels below 12 G. These were all asked to supply three specimens of faeces for testing for occult blood, except 10 women whom it was thought injudicious to include in this part of the study, as they were already receiving iron therapy from their general practitioners. Of the other women 19 refused and 91 (83%) each supplied three specimens. These data, together with the results of Hematest examinations by two independent observers, are shown in Table III. One or more samples from 15 subjects (16% of those tested) gave a definite positive result, though only in four (4%) was there agreement between the two observers. There is no evidence of any association between the proportion of positive results with haemoglobin level. Indeed, none of the seven with levels below 8 G. who were tested had evidence of faecal occult blood. A representative sample of 69 women with haemoglobin levels above 12 G. were contacted, and the 64 (93%) who co-operated were tested in the same way. Of these, five (8%) gave a positive result, and, though this is lower than

TABLE III.—Details of Samples Tested by Hematest for Faecal Occult Blood on Three Occasions by Two Independent Observers

No. of tests in which there was agreement between the two observers shown in parentheses.

the proportion in women with haemoglobin levels below 12 G. found to be positive, it does not differ from it significantly. Each of the 20 women with a positive result was visited again, asked about rectal bleeding, and asked to supply a further three faecal specimens. Eight said they had haemorrhoids which bled occasionally, and faecal specimens from four of these gave a second positive Hematest. Other than these none of the women had a second positive test.

Almost all the women with haemoglobin levels between 8 and 12 G. were admitted to the clinical trial of the effect of iron therapy on symptoms. Detailed results will be presented elsewhere; suffice to say here that there was no evidence of a beneficial effect of eight weeks of conventional iron therapy on the symptoms of irritability, palpitations, dizziness, breathlessness, fatigue, or headache which was greater than that of identical placebo tablets which contain no iron.

There were no significant differences between the basic population and the spontaneous attenders in any attribute or variate measured, other than in weight. The spontaneous attenders were 6.8 ± 2.1 lb. (3.1 ± 0.95 kg.) heavier on average than the basic population. Apart from this difference the two groups were homogeneous with respect to age, parity, height,

TABLE IV.—Summary of Comparisons Between Spontaneous Attenders and the Basic Population

triceps skin-fold thickness, haemoglobin level, P.C.V., symptom grades, and their own estimates of the number of visits to a general practitioner during one week, one month, and one year immediately before the survey (Table IV).

Discussion

Screening for disease should be regarded as one step in the diagnostic process and not as an end in itself. Thus a general practitioner seeing his surgery attenders, or a consultant physician his outpatients, are simply forms of screening and fundamentally differ little from community screening procedures. However, a realistic evaluation of any screening procedure cannot be made without consideration of the benefit, if any, which results from the screening, and this aspect often seems to be ignored—for example, by Horne *et al.* (1967) in their report of a local health authority screening survey. Acheson (1963) lists five criteria which ideally should be fulfilled before any health-screening procedure is instituted, and similar criteria are incorporated in the discussion by Wilson (1963). These criteria include matters relating to the prevalence of the condition being sought, its importance, the sensitivity and specificity of the tests required for its diagnosis, the acceptability of this test by the subjects screened, and the acceptability and effectiveness of treatment available for those found to have the condition sought. Few diseases, if any, fully meet all the criteria outlined, but Acheson (1963) specifically mentions anaemia as probably fulfilling all the criteria except perhaps those relating to its importance in terms of morbidity and mortality.

Our study, however, appears to us to give very little encouragement for community health screening for anaemia. Though a fairly high proportion of women were detected with haemoglobin levels below commonly accepted lower limits of normal, thus being consistent with data obtained in the community surveys of Kilpatrick (1961), Elwood (1964), and others, yet the importance of "anaemia," so defined, appears to be relatively small. This assessment of importance is based both on the apparent absence of serious treatable underlying conditions in the subjects with the lowest haemoglobin levels and on the absence of unequivocal benefit in the symptoms of those treated with iron. Even in those in whom further action was taken, in only one was there evidence of serious disease, and this was almost certainly a chance finding, unrelated to the anaemia. Furthermore, the relevance to anaemia of the other conditions treated—haemorrhoids and menorrhagia—and the success of the treatment given, can strictly only be assumed, as we made no quantitative measurements of blood loss.

It might be argued that our subjects were not investigated with sufficient thoroughness to detect all serious underlying disease. In particular it could be pointed out that all the subjects whose faecal specimens were positive to Hematest were not exhaustively investigated. This criticism is valid, but one of the main aims of this survey was to evaluate the existing facilities for further investigation and not to create an unrealistic situation. So far as possible, therefore, subjects were treated at the local hospital as if they had been normally referred by local general practitioners. In any case, further detailed investigation of subjects identified in this way, most of whom had no definite gastrointestinal symptoms, is not easily justified, and can be easily misunderstood and possibly resented. However, almost all the women found in this survey to have haemoglobin levels below 12 G. are involved in further epidemiological studies and will be followed for a considerable time.

With regard to the data relating to positive Hematests, it appears that much further work would need to be done to enable a "positive" result to be defined more clearly and to evaluate positive results, in particular with regard to their relevance to low haemoglobin levels in the community. Illingworth (1965) showed that the diet must be carefully controlled to a considerable degree before a positive Hematest is accepted as firm evidence of gastrointestinal bleeding, but even with careful dietary control Ross and Gray (1964) feel that "no value can be attached to the results of any of the chemical tests" for occult blood, and they feel it is questionable whether these tests should be retained in modern medicine. It is not felt justified in the present study to attempt to control the diets of the subjects in any way, but in spite of this and the view expressed by Ross and Gray (1964) the difference in the prevalence of positive tests in the subjects with haemoglobin levels below 12 G. and in those with haemoglobin levels of 12 G. or more, all of whom were tested in exactly the same way by "blind" observers, is of interest in an epidemiological context.

It was possible to examine aspirin-taking in these women, as questions relating to this had been asked routinely in the initial survey, and there was no evidence that the women with positive Hematests took aspirin more often than the other women. In fact the difference, though not significant, suggested the reverse. Interpretation of these data as they stand is therefore difficult, though it is of interest that our estimate of 16% positive tests in the women with lower haemoglobin levels is not very different from that obtained by Illingworth (1965) in 126 "normal people eating an unrestricted diet" (21% quoted in text, 31% shown in Table). The results of this part of the study are therefore equivocal, but make it seem unlikely that serious underlying disorder is a causative factor of any magnitude in iron-deficiency anaemia in the community. The present data therefore give no support to the view that "in the adult (the

basic disease process) is all too frequently a malignant tumour of the gastrointestinal tract" (Harris, 1963).

Backett (1960) has stressed that high-risk groups should be identified for screening procedures. In an approach to the community as a whole this would be achieved to some extent if the less healthy persons more readily attended surveys such as the one described here than the rest of the community. The data presented here show that this is most unlikely to be the case in a survey for anaemia, as the persons who spontaneously attended the clinic differed from the basic population in none of the ways examined, other than in weight. It is difficult to interpret this difference in weight, but in the absence of any other significant difference it is unlikely to be of clinical importance.

Further data which bear indirectly on this aspect of health screening can be obtained by examining the trend in mean haemoglobin during the survey. If the women who attend a survey such as ours least readily are those with, on average, higher or lower haemoglobin levels, then the mean levels of successive groups of subjects, examined in the order in which they attended, should show a rise or a fall. In fact the mean level of the last 67 women, most of whom required considerable persuasion to attend the survey, was 13.9 ± 0.20 G., and though this is higher than the mean of the whole basic population (13.3 ± 0.05 G.) the difference is not significant. It appears likely, therefore, that neither the women who attend a survey most willingly nor those who attend most reluctantly differ with regard to their haemoglobin level from the population from which they come. In fact the absence of a real difference in the distributions by haemoglobin level had been predicted in view of the lack of evidence in an earlier community survey of a significant association between haemoglobin level and symptomatology (Wood and Elwood, 1966). In view of the fact that the symptoms examined in our study are not specific for iron deficiency, our data suggest that in any screening survey of the type we conducted high-risk groups are unlikely to attend selectively to any important extent.

Summary

An evaluation of a community screening survey for anaemia has been made. This is based on the proportion of women found to have a low haemoglobin level in a large survey, the proportion of these found to have a serious underlying disorder, and the symptomatic benefit in them after iron therapy. In addition, the selection of women who voluntarily attend a screening survey is examined by comparing the distributions of a wide variety of variates in a large group of women who spontaneously attended the survey with these distributions in the whole community. These studies give very little encouragement for ad hoc community screening.

Brit. med. J., 1967, 4, 718-720

During the proteolysis of fibrinogen and fibrin by the fibrinolytic enzyme plasmin several large fragments are released which are incapable of undergoing further digestion (Nussenzweig and Seligmann, 1960; Alkjaersig *et al.*, 1962). Some of these fragments, with a molecular weight of approximately 88,000, contain an antigenic determinant which is identical to the parent fibrinogen (Nussenzweig *et al.*, 1961). An accurate quantitative estimation of circulating fibrin/fibrinogen degradation products (F.D.P.) would be of considerable importance in investigations of physiological and pathological states of coagulation and fibrinolysis, for circulating F.D.P. represent a certain criterion that fibrinolysis is taking place. They play a significant part in the pathogenesis of certain bleeding disorders (Niewiarowski *et al.*, 1959; Fletcher, 1966; Jerushalmy and Zucker, 1966; Kopic *et al.*, 1966); they may be of importance in the physiological control of the microcirculation (Buluk *et al.*, 1966) and could provide valuable information in further studies on the hypothesis of a continuous dynamic equilibrium between fibrin deposition and fibrinolysis postulated to be an important aetiological factor in thrombosis and atherosclerosis (Astrup, 1956).

While prolongation of the thrombin time has been advocated as a useful screening procedure for estimating high levels of F.D.P. in pathological fibrinolysis (Sherry, 1965), the method is devoid of specificity, has poor sensitivity, and is therefore of limited value. The application of immunological techniques such as immunodiffusion and immunoelectrophoresis has greatly extended the specificity and sensitivity of F.D.P. assays. Further progress has been made with the use of a tanned red cell haemagglutination inhibition immunoassay (Murakami, 1965a; Merskey *et al.*, 1966) which has been claimed to be more sensitive and more easily adapted to accurate quantitative estimation of circulating F.D.P. than either immunodiffusion or immunoelectrophoresis. This investigation was designed to establish the normal range of serum F.D.P. values before the study of those pathological conditions believed to be associated with excessive focal or disseminated intravascular coagulation and to extend our studies of the Astrup hypothesis. This communication describes our experiences with the tanned red cell haemagglutination inhibition immunoassay in a group of apparently healthy subjects.

Methods

A total of 106 healthy volunteers (62 male and 44 female) aged 21-64 years (mean 40 ± 15) were studied. Cubital venous blood samples were obtained by clean venepuncture with the minimum venous occlusion, a plastic disposable syringe being used, after a period of 20 to 30 minutes' rest.

Five millilitres of blood was added to a non-siliconized glass test-tube containing 0.1 ml. of Trasylol (5,000 units/ml.) and placed in a water-bath at 37° C. for four hours. The serum was removed after centrifugation at 2,000 r.p.m. for 10 minutes, and one-tenth of its volume of thrombin (100 units/ml.) was

added and incubated for 30 minutes at 37° C. to remove any residual fibrinogen. F.D.P. assays were performed by the method of Merskey *et al.* (1966) on serum samples which had previously been absorbed for two hours at 4° C. with one volume of saline-washed normal sheep red cells to two volumes of serum. Rabbit anti-human fibrinogen serum supplied by Hoechst Pharmaceuticals Ltd. was used in the immunoassay. Daily controls were run with standard solutions of human

fibrinogen prepared by the Blombäck and Blombäck method and supplied by Kabi Pharmaceuticals Ltd. The quantity of clottable protein in these solutions was checked periodically by the method of Ratnoff and Menzie (1951) as modified by Alkjaersig (1960). The immunoassay was sufficiently sensitive to demonstrate fibrinogen levels of 0.6 µg./ml.

A further 9 ml. of blood was added to 1 ml. of 3.8% sodium citrate, in a previously cooled siliconized glass centrifuge tube,

and centrifuged at 4° C. for 20 minutes at 3,400 r.p.m. Euglobulin lysis time assays were performed by the method described previously (Cash, 1966), but the clot lysis end-point was recorded objectively by means of an automatic clot lysis recorder (Cash and Leask, 1967). The euglobulin lysis activity was expressed in arbitrary units derived from the formula 1300/T of Janusko and Dubinska (1964), where T was the euglobulin lysis time in minutes.

Results

Normal Resting Level of Serum F.D.P.—The mean serum F.D.P. level of 147 samples from 106 subjects was 4.9 ± 2.8 $\mu\text{g./ml.}$ The distribution of these values is shown in Fig. 1, and it can be seen that the immunoassay was able to detect F.D.P. in all but 2% of the serum samples. No significant sex difference was shown, nor was there a consistent change in serum F.D.P. throughout a menstrual cycle in the four women studied. Table I gives the individual variation in serum F.D.P. of 12 subjects from whom blood was withdrawn at weekly intervals, whereas Table II shows the variability of the assay system on aliquots of eight serum samples which were stored at -40°C. and assayed at weekly intervals.

Exercise and Adrenaline Studies.—Table III shows the serum F.D.P. levels in 26 subjects before and after an eight-minute exercise procedure on a treadmill moving at 3.4 m.p.h. (5.5 k.p.h.) at 5 degrees elevation, and in five subjects before

and two minutes after a two-minute intravenous infusion of 10 $\mu\text{g.}$ of adrenaline per minute (Parke-Davis and Co.). Statistical analysis of these results by Student's *t* test showed the resultant increases of serum F.D.P. to be significant (exercise, $t=5.922$, $P<0.001$; adrenaline, $t=3.03$, $0.005<P<0.01$).

Correlation Between Serum F.D.P. and Euglobulin Lysis Activity.—A plot of the resting serum F.D.P. values and plasma euglobulin lysis activity in 75 samples (Fig. 2) shows a significant correlation between these two criteria ($r=0.226$; $0.02<P<0.05$; $y=6.82+0.20x$).

Discussion

There are few studies on the detection of F.D.P. in the serum of normal subjects: Ferreira and Murat (1963) and Ferri and Ferreira (1963), using a "fibrin degradation flocculation test" and immunoelectrophoresis, found no evidence of circulating F.D.P. in normal subjects; Niléhn and Nilsson (1964), using comparative immunoelectrophoresis in agar gel, demonstrated F.D.P. in the serum in 5 of their 28 normal subjects; and Murakami (1965b), employing the tanned red cell haemagglutination inhibition immunoassay, observed lysis products without exception in 69 cases, including normal controls, whereas Merskey *et al.* (1966), using the same basic method, demonstrated the presence of F.D.P. in only 3 out of 33 controls.

The present investigation indicates that the tanned red cell haemagglutination inhibition immunoassay can show a serum F.D.P. content in about 95% of normal serum samples. This high incidence of detection in normal sera does not accord with the findings of Merskey *et al.* (1966) but is similar to the observations of Murakami (1965b). At the present time it is not possible to explain these different results, but the greater sensitivity of our immunoassay and small differences in technique, reagents, and sheep red cells may be relevant factors. It is also possible that there was a difference in the age and sex ratio of the normal populations studied in the three different centres.

In view of the pathophysiological significance of these findings it is important to be certain that the assay system is in fact detecting products of degradation of in-vivo fibrin by the fibrinolytic enzyme system. It is possible that the fibrinopeptides (Blombäck *et al.*, 1966) released during the clotting of the plasma fibrinogen were reacting positively in the immunoassay. However, we have shown that the supernatant, obtained after the incubation at 37° C. for 30 minutes of purified fibrinogen with thrombin in the presence of Trasylol, does not produce haemagglutination inhibition. It is also possible that residual traces of fibrinogen remained in the sera despite the addition of thrombin. We have no evidence to substantiate this view and have found no correlation between the plasma fibrinogen and level of serum F.D.P. in 20 subjects.

Previous studies have indicated that exercise and adrenaline will bring about an increase in activity of both the coagulation and fibrinolytic enzyme systems (Biggs *et al.*, 1947; Forwell and Ingram, 1957; Genton *et al.*, 1961; Iatridis and Ferguson, 1963; Burt *et al.*, 1964). The demonstration of a highly significant increase in circulating F.D.P. after these fibrinolytic stimulants would suggest that previous assumptions related to an increase in coagulation and fibrinolysis are valid and that the haemagglutination inhibition immunoassay is detecting levels of F.D.P. Further collateral evidence in favour of latter point was obtained by the observation of high level F.D.P. in a patient with severe haemorrhagic diathesis by a primary fibrinolysis associated with a hypernephroma; this patient the F.D.P. level fell precipitously and stopped after the administration of aminocaproic acid. Subsequent efforts to withdraw the aminocaproic acid resulted in a rapid rise of serum F.D.P., associated with a return of the bleeding which was again controlled by resumption of the administration of aminocaproic acid.

Though we showed a positive correlation between the resting levels of circulating F.D.P. and the plasminogen activator in normal subjects the relation was not highly significant. This indicates that the concentration of circulating F.D.P. is probably the end-result of a complex dynamic system which will include fibrin deposition and active fibrinolysis associated with fibrinolytic inhibition.

It cannot be assumed that the results of our study necessarily represent definite proof of continuous in-vivo intravascular coagulation and fibrinolysis as envisaged by Astrup, though the exercise and adrenaline studies are very suggestive. More information is required on the rate of excretion of circulating F.D.P. in physiological circumstances, for if the present concept of a half-life of approximately nine hours is substantiated (Sherry, 1965), then the resting values obtained in this study could merely represent the end-product of transient episodes of exercise or anxiety which occurred several hours before the blood was withdrawn. Furthermore, we have no proof that these F.D.P. are derived from intravascular deposits of fibrin, for it is possible that they may represent a by-product of minute damage and repair within the tissues. Further work on these problems is in progress.

Summary

From 106 apparently healthy subjects 147 serum samples were assayed for their fibrin degradation product (F.D.P.) content by the tanned red cell haemagglutination inhibition immunoassay technique. In 98% of these samples it was possible to detect a measurable quantity of F.D.P., the mean value being 4.9 ± 2.8 $\mu\text{g./ml.}$ There was no significant sex difference or a consistent change during the menstrual cycle. Further studies with the use of exercise and intravenous adrenaline were carried out in order to evaluate the significance of these findings in relation to the concept of an in-vivo dynamic equilibrium between coagulation and fibrinolysis.

We wish to thank Dr. R. A. Cumming, Director of the South-East Scotland Regional Blood Transfusion Centre, who has been responsible for the provision of our excellent laboratory facilities and has given us much encouragement and helpful advice, and Dr.

A. E. Robertson, who kindly assisted in obtaining the co-operation of many of our subjects. Finally we wish to express our sincere appreciation to Dr. Clarence Merskey, of the Albert Einstein College of Medicine, New York, U.S.A., whose helpful correspondence maintained our interest and played a significant part in the successful development of this assay. This research programme was supported by a grant from the Scottish Hospital Endowments Research Trust. One of us (P. C. D.) was in receipt of a postgraduate scholarship from the Government of East Pakistan.

Requests for reprints should be addressed to Dr. J. D. Cash, South-East Scotland Regional Blood Transfusion Research Laboratories, Royal Infirmary, Edinburgh 3.

Medical Memoranda

Malignant Tumour of Brown Fat in Patient with Turner's Syndrome

Brit. med. J., 1967, **4**, 720-721

CASE REPORT

A 24-year-old typist was first seen in January 1966, when she complained of a slowly enlarging painless swelling in the right scapular region that had been present for one year. She had no other complaints, but on systematic questioning it was noted that she had primary amenorrhoea.

On examination there was a non-tender subcutaneous swelling measuring 5 by 5 cm. below the right scapula. The tumour was not attached to skin but was attached to deep structures. There were no signs of inflammation, but there were some dilated veins over the tumour. The patient had a short stature with a total height of 54 in. (137 cm.) and an arm span of 60 in. (142 cm.). She had unusual facies with a small mandible, prominent inner canthal folds, and large low-set ears. There was no webbing of the neck or cubitus valgus, but she had a low hair-line with

syndactyly of the fingers and toes. The chest had a shield-like configuration. Breast development was present but slight. Pubic and axillary hair were scanty. Blood pressure was 135/90 mm. Hg. Hypoplastic genitalia were noted on pelvic examination, and the ovaries could not be palpated.

Investigations.—X-ray examination showed a normal sella turcica and small facial bones; the radial and ulnar epiphyses had not united, but fusion had occurred at all the epiphyses of the elbow. 17-Ketosteroids 4.3 and 5.5 mg./24 hours. 17-Hydroxycorticosteroids 12.4 and 4.4 mg./24 hours. After four days' A.C.T.H. stimulation 17-KS was 27.8 and 17-OHCS was 26 mg./24 hours. Gonadotrophins 1.8-3.6 $\mu\text{g./24 hours}$. Buccal smears showed a chromatin-negative pattern.

Five hundred neutrophils were examined and only one type A and three type B appendages were seen (normal for female is six or more). There was a predominance of type C nuclear appendages that are seen more often in the male. Blood culture gave a good growth of cells for chromosome studies. The modal number was 45. Karyotypes from several cells showed the chromosome pattern of Turner's syndrome 45/XO. However, a few cells with 46 chromosomes showed the normal number of chromosomes (16) in group C. The probable diagnosis seemed to be a mosaic with some cells containing 45/XO chromosomes and others 46/XX.

At operation a lobulated flabby vascular tumour was partially removed deep to the latissimus dorsi. Though the tumour was mainly encapsulated a radical excision was not possible, since part of it was attached to the spinous process and lamina deep to the surface of the erector spinae muscle.

The specimen consisted mainly of lobulated tumour tissue infiltrating between muscle bundles. It was more reddish brown than fat. Histologically the tumour consisted of fat cells that varied considerably. Some approached the adult type but others had a rounded outline and contained cytoplasm of fine foaming granules of fat (see Fig.). The tumour was not well encapsulated, and there was an intimate relation between the tumour elements and the muscle bundles. The tumour resembled a hibernoma, but in view of the intimate infiltration between muscle bundles it was treated as a form of liposarcoma.

Photomicrograph of tumour.

As a result the residual tumour bed was irradiated with megavoltage x rays to a dose of 4,500 rads in five weeks. The geometry of the treatment fields had to be carefully arranged to avoid irradiating the spinal cord. This hampered a radical approach.

The patient was finally discharged from hospital on a regimen of cyclical oestrogens. At follow-up clinic she remained well, and there was no evidence of tumour recurrence. In addition she had her first episode of breakthrough menstrual bleeding after four and a half months on a priming dose of ethinyloestradiol.

Case of Mumps Nephritis

Brit. med. J., 1967, 4, 721-722

An association between mumps and renal involvement has been infrequently reported. In a series of 20 cases of mumps in Servicemen, Utz *et al.* (1964) reported demonstrable transient renal impairment in all cases. There were no symptoms. In all previously reported cases of mumps in which symptoms of renal damage have been present, death has occurred.

CASE REPORT

The patient, a girl of 15 years, weighing 7 st. 3 lb. (45.8 kg.), was admitted to hospital on 15 January 1967. She gave a history of bilateral parotid mumps two weeks previously. She had been a contact. Her presenting symptoms were enlarged cervical glands, intermittent vomiting, fever, and a petechial rash on the right forearm accompanied by periorbital oedema of four to five days' duration. The latter two features developed some 24 hours after a dose of Metatone (a proprietary preparation containing vitamin-B complex, glycerophosphate, and strychnine), prescribed by her general practitioner for listlessness. No other drug history was elicited.

C

COMMENT

Since the description by Turner (1938) of seven examples of sexual infantilism, congenital web neck, and cubitus valgus in females of short stature many additional abnormalities have been described (Lemli and Smith, 1963).

Hibernoma, or brown fat lipoma, is a rare variant of simple lipoma. Only a small number of cases have been reported in the literature (Sandison and Graham, 1959). The tumour arises in brown "hibernating" fat usually found only in human embryos and hibernating animals. The brown fat lipoma has always been described as a simple tumour. So far as we know this is the first report of malignant degeneration in this tumour.

The infrascapular site of the tumour is of interest, since it is mainly in this site that brown fat is found in mammals (Dawkins and Hull, 1964). Moreover, at one time the hibernoma was called the interscapular tumour.

The unusual occurrence of a rare tumour in a patient with Turner's syndrome is of added interest, since it is recognized that chromosomal damage can lead to malignant disease. In addition, recent studies suggest that certain cancers and congenital defects occur together more often than can be attributed to chance (Miller, 1966).

We are indebted to Dr. J. E. Morison and Dr. W. R. M. Morton for the histological and chromosome investigations. We should also like to thank Dr. A. R. Lyons, Dr. D. A. D. Montgomery, and Dr. D. R. Hadden for their friendly interest and advice.

Flitting knee arthralgia was present for a period of 24 hours after admission. There was no recent cough or sore throat.

She had been admitted to hospital with abdominal pain seven months previously. Spontaneous remission occurred 24 hours later. She was allergic to sticking plaster, but no other history of allergy was obtained.

On clinical examination she was flushed, with an oral temperature of 103° F. (39.4° C.). The tongue was dry and furred. Also evident was bilateral non-tender cervical adenitis and parotid fullness. Petechial haemorrhages were present on the roof of the hard palate and right antecubital fossa—the Hess test was positive on two successive days. On admission her pulse was 110/minute and her blood pressure 110/70 (see Fig.). Clinically, there was no evidence of tonsillitis or pharyngitis. At no stage did she have pretibial oedema. Her temperature was raised for the first 24 hours only.

In spite of a poor fluid output in the first 36 hours, her fluid balance throughout remained reasonable apart from impairment of urine concentration initially. Daily ward urine analysis showed varying amounts of blood and albumin. Early morning midstream specimens produced from a few to numerous red blood cells on microscopical examination. Protein content of urine varied from 0.5 to 2 g./24 hours. Two specimens were productive of occasional granular casts. No pathogen was isolated from the urine. Blood urea and erythrocyte sedimentation rate (E.S.R.) were raised for the

first two weeks; the highest values were a blood urea of 114 mg./100 ml. and an E.S.R. of 50 mm./hour. Antistreptolysin titre (A.S.O.) estimation was 100 international units on the seventh hospital day, and 200 international units 61 days later. Mumps virus serology performed on the first and fourteenth hospital day showed a fourfold increase in titre (+1/20 to +1/80) compatible with a recent mumps infection. Hypertension developed in the first week. The highest diastolic pressure recorded was 130 mm. Hg. There was spontaneous regression without treatment. Total white blood count ranged from 10,000 to 7,000/cu. mm., with normal differentials throughout. Platelet counts on the second and seventh days of illness were 200,000 and 210,000/cu. mm. respectively. Four throat swabs and blood cultures were negative. Serum amylase was 4 units. Serum electrolytes were normal throughout. Paul-Bunnell agglutination was negative. Her management was along symptomatic lines.

Dietary protein was restricted to 35 g. daily, on a fluid load of 2.5 litres/24 hours, until improvement became evident. A course of phenethicillin and chlorpheniramine had no obvious therapeutic effect. Improvement occurred during her stay in hospital, as evidenced by the return of the blood urea and E.S.R. to normal values, the disappearance of haematuria, and the marked diminution of proteinuria.

COMMENT

Epidemiological data from Norway in the pre-insulin era suggested a connexion between waves of mumps and increased incidence of diabetes mellitus some years later (Gundersen, 1927).

It is recognized that in some children the swelling of the salivary glands in mumps is replaced by a lymphadenitis in the

Treatment and progress in case of mumps nephritis.

neck (*Lancet*, 1961). The 1961 mumps epidemic in the United Kingdom differed from previously recognized forms of the disease because of the frequency of gastrointestinal upsets. These observations suggest that medical interest in this condition should no longer be focused exclusively on the salivary glands, pancreas, and nervous system. More recently it has been pointed out that a connexion may exist between gestational

mumps and primary endocardial fibroelastosis (St. Geme *et al.*, 1966; Gersony *et al.*, 1966).

A review of the literature produced four cases of nephritis complicating mumps. They were all fatal. In none of these cases was hypertension reported as being a prominent feature (see Table).

Contrasting Features of Mumps Nephritis and Post-streptococcal Glomerulonephritis

	Mumps Nephritis (5 cases)	Post-streptococcal Glomerulonephritis
Throat infection	Nil	90%
"Latent period"	1-3 weeks	3-5 weeks
Cervical adenitis	1/5 in some children	Nil
Throat culture	Nil	Positive in 80-90%
Pyrexia of more than 101° F. (38.3° C.)		+ 90%
W.B.C. more than 10,000 cells/ cu. mm.		100%
E.S.R. more than 30 mm./hr. ..	1/5	100%
A.S.O. more than 250 i.u. ..	Nil	+ 90%

In the present case the possibility of a Metatone-induced nephritis can be excluded on clinical grounds. Previous administration had been without ill effect. The significance of a transient hypertension and its late sequelae are difficult to assess. In view of the patient's rapid improvement and subsequent complete clinical recovery, we did not consider it justifiable to submit her to the added trauma and possible complications of a renal biopsy.

"Viral infection" has been suggested as a cause of some nine cases of acute glomerulonephritis not associated with group A streptococcal infection (Bates *et al.*, 1957). More specifically, three cases (in children) of fatal nephritis developing after mumps infection in the absence of serological or cultural evidence of streptococcal infection have been reported (Hughes *et al.*, 1966).

We suggest that the present case may not be unique and that such cases may not be unusual in adults.

If this possibility of a mumps infection as a cause of acute nephritis can be accepted on the evidence presented, then the mumps virus must be added to the lengthening list of nephropathic "agents."

Current Practice

DISEASE OF THE DIGESTIVE SYSTEM

Bleeding from the Upper Gastrointestinal Tract

G. N. CHANDLER,* D.M., M.R.C.P.

Haematemesis and melaena are symptomatic of haemorrhage into the upper gastrointestinal tract. When such bleeding has occurred the patient will almost always volunteer the information that the blood, if it has been vomited, has come from the stomach. Occasionally the origin of the blood may not be immediately obvious—as when haematemesis occurs as an isolated symptom in a previously healthy person—and there may also be difficulty when the supposed blood vomit has not been kept to be seen by the doctor. Examination of the stools will resolve any such doubts. Haematemesis never occurs without some blood appearing in the stools, and even in the absence of melaena chemical examination of the faeces will show the presence of much more blood than could be accounted for by other means.

Incidence and Mortality

Haematemesis is one of the commonest medical emergencies that may threaten life, and of the complications of peptic ulcer it is the most frequently encountered. Estimates of the clinical incidence of haematemesis vary from a quarter to approximately a third of all patients with peptic ulcer. The tendency to bleed is about the same during the whole course of the disease, with the exception of the first year, in which it is somewhat greater. Most published series show a mortality rate of between 5% and 10% under conservative medical treatment. However, if only examples of massive haemorrhage are considered the death rate is higher. Massive bleeding is defined as haemorrhage that is accompanied by shock, a lowering of the red cell count to 3,000,000/cu. mm. or less, and a haemoglobin level below 50%. With these criteria of selection the mean mortality rate is about 15%, with a range of 4% to 66%.

Though the mortality from haemorrhage in chronic ulcer is considerably higher than in bleeding from acute lesions, the most important correlation is with age. Below 45 years the death rate is small, but it increases sharply after the age of 60; in most western countries haematemesis is steadily increasing both in frequency and severity as the age structure of communities alters with increasing numbers of older people.

Cause of Bleeding

Peptic ulcer is easily the most important cause of haematemesis and melaena, accounting for about 9 out of every 10 admissions, but rather more than a quarter of these patients have no demonstrable radiological abnormality when examined after bleeding has ceased. Nevertheless, gastroscopy or gastro-camera inspection performed in the early stages of illness will reveal the presence of an acute ulcer in over half of this group with negative x-ray findings. These lesions heal quickly, and

it is in this group that aspirin consumption makes its appreciable contribution to the number of hospital admissions for upper gastrointestinal bleeding.

Haematemesis and melaena are not uncommon complications of carcinoma of the stomach, but the diagnosis has usually been made before the onset of bleeding. In these cases the loss of blood is generally small, though exceptionally, as in the ulcerating type of cancer, it may be profuse. As the blood remains in the stomach for some time before it is vomited, it is generally coffee coloured and mixed with food and mucus.

Haemorrhage from oesophageal varices is not uncommon in cirrhosis of the liver, but confusion in diagnosis may occur since there is often a dyspeptic history and sometimes an associated ulcer. Bleeding from an oesophageal growth is rarely an early symptom and a diagnosis is likely to have been made already on account of dysphagia. Likewise an aortic aneurysm leaking into the oesophagus will almost certainly have given rise to other symptoms and signs to betray its presence. Oesophageal hiatus hernia, sliding or fixed in character, is a common gastro-enterological lesion, and bleeding may occur either from an associated oesophagitis or from a gastric ulcer straddling the region of constriction at the level of the diaphragm.

Certain blood dyscrasias may be associated with haematemesis and melaena, but they are infrequent causes of these symptoms. Nevertheless, when the source of bleeding is not obvious nor the history typical the possibility of an underlying haemorrhagic diathesis should always be investigated. Usually a history of bleeding elsewhere will be obtained. Anticoagulants should not be given to patients with known gastroduodenal ulceration, but nevertheless patients on anticoagulant treatment can develop acute ulceration.

Symptoms and Signs

The clinical picture in massive haemorrhage is dominated by the development of shock. The patient is pale both from blood loss and compensatory vasoconstriction. The pulse is rapid and small; there may be marked sweating. One of the first changes to be recorded is a fall in blood pressure, and repeated measurements are essential in estimating cessation of recurrence of bleeding. Restlessness may be extreme, and rapid shallow respirations are of grave import. It is usual for any ulcer pain preceding the bleeding to disappear with the onset of haemorrhage, and the persistence of pain of any severity should always suggest the possibility of concomitant perforation, a particularly lethal combination.

The management of patients with haematemesis and melaena depends to a large extent on the diagnostic probabilities, and an adequate history should be obtained either from the patient or, if he is too ill, from an informed relative. Inquiry should be made for any antecedent history suggestive of peptic ulceration, and any record of perforation or previous radiological confirmation of the existence of an ulcer is extremely valuable.

* Consultant Physician, Chapel Allerton Hospital, Leeds.

The physical examination of these patients should be undertaken with care so as not to exhaust them. The severity of the bleeding will be immediately apparent and should be confirmed by measurement of pulse rate and blood pressure. Abdominal examination must include palpation for an enlarged spleen and an epigastric mass. The existence of a collateral circulation in hepatic cirrhosis is diagnostic of this condition. Malignant disease of the stomach may suggest its presence by a palpable tumour and enlarged glands in the supraclavicular fossa. An assessment of the extent of arteriosclerotic change in older patients is important and demands examination of the superficial arteries and the fundi. Where thrombocytopenic purpura is suspected, a tourniquet test with a sphygmomanometer cuff should be carried out.

Principles of Treatment

There is no longer any controversy about the advisability of liberal feeding. Most patients tolerate bland diet extremely well, given two-hourly with sufficient fluid to correct dehydration and maintain an adequate urinary output. Confinement to bed is essential if bleeding continues and morphine 15 mg. or sodium phenobarbitone 200 mg. may be given to allay restlessness or anxiety. Pulse rate and blood pressure should be measured hourly and the details recorded, together with any further episode of bleeding, on a chart available at the bedside.

There can be no hard-and-fast rules on when blood transfusion is required. While determinations of blood volume would enable the clinician to assess the amount of blood lost accurately, such techniques are as yet unsuitable for routine use and reasonable indications for transfusion are a pulse rate of 110 or more or a systolic blood pressure of 110 mm. Hg or less. Such patients need transfusion urgently, and prompt action is particularly important in the elderly to prevent the irreversible cerebral damage that may complicate prolonged shock. If severe anaemia is allowed to develop a compensatory increase in venous pressure leads to greater cardiac filling and improved cardiac output. This hyperkinetic phase is shown by the presence of a full, bounding pulse, raised pulse pressure, and jugular venous distension. The venous pressure also rises during the initial stages of transfusion, and though it falls again as the arterial pressure rises overtransfusion carries the risk of precipitating heart failure. Ideally part of the replacement after massive bleeding should consist of packed red cells to minimize the possibility of overloading the circulation and to reduce the risk of pulmonary oedema. Usually gastroduodenal bleeding stops within 12 or 24 hours of admission, most often permanently, and during this time 1,500–3,000 ml. of blood may be given by slow drip transfusion (40 drops per minute). Occasionally there is a continuous slow loss of blood requiring intermittent transfusion, and this seems to happen most commonly in patients bleeding from acute lesions; the vessels from which an acute ulcer bleeds are mostly small and submucosal, and such bleeding lacks the dramatic quality of arterial haemorrhage from the base of a chronic ulcer. Exceptionally, chronic ulcers bleed so severely that the only hope for the patient lies in intra-arterial transfusion and immediate operation.

Transfusions of 500 ml. are unnecessary and wasteful. Large volumes of blood given rapidly carry risks of citrate intoxication and hyperkalaemia. The former may lead to defective clotting and myocardial failure and it is wise to give 10 ml. of 10% calcium gluconate intravenously after every fourth bottle of blood. Potassium intoxication carries the very real threat of cardiac arrest—particularly if bank-blood near the limit of its expiry is used—when serum potassium levels may reach 25 mEq. Warming the blood before use will encourage the return of potassium to the cells and the danger can be further diminished by the infusion of dextrose solutions. However, when such massive transfusions are in question the need for surgical arrest of haemorrhage should be urgently reviewed.

Medication other than vitamin concentrates is best avoided, though iron may be given by mouth from the start. Constipation is the rule after haematemesis and is usually well tolerated by the patient. Purgatives should not be administered, but there is no contraindication to the giving of an enema or the use of a glycerin or Dulcolax (bisacodyl) suppository.

Time in Bed

There is no reason why the patient whose course is uncomplicated should not be allowed up by the second or third day in hospital. There is no evidence that recovery after haematemesis is hastened by confinement to bed, the dangers of which are obvious, especially in older people with associated degenerative disease.

The management of bleeding from oesophageal varices consequent on cirrhosis will be considered in a separate article. Some of these patients die from haemorrhage long before the reduction of hepatic function has become a threat to life.

Though brisk continued bleeding from peptic ulcer is an indication for surgical treatment, there are a few patients in whom operation is out of the question because of severe associated disease or overwhelming senility. Nevertheless, however unpromising the prognosis may appear, neither hope nor treatment should be abandoned. Distension of the stomach with blood clot may be an important factor preventing the atonic stomach of a shocked patient from arresting the bleeding by contraction. Emptying the stomach with a Senoran's evacuator followed by lavage with ice-cold water may help to stop bleeding. The use of a topical haemostatic such as thrombin after lavage with 1:1000 adrenaline has been advocated in the treatment of bleeding acute peptic ulcer. In such cases the stomach should first be emptied through a large bore tube and then washed with 1:1000 adrenaline; finally, thrombin in a suitably viscous vehicle as methylcellulose is instilled into the stomach. Gastric cooling has not won any wide acceptance either for the treatment of bleeding peptic ulcer or for haemorrhage from oesophageal varices using an oesophageal extension of the gastric balloon.

Early Diagnosis in Haematemesis

The difficulty of treating bleeding peptic ulcer largely concerns the detection of those patients in whom the prognosis with medical measures must be considered poor and who will bleed to death unless surgery is employed. The problem, however, is not always easily solved. Acute ulceration or erosion of the stomach or duodenum is a common lesion which usually responds well to medical treatment. Unfortunately this diagnosis is not always obvious, being largely based on negative evidence and frequently confirmed only in retrospect by a negative x-ray. The vessels from which an acute ulcer bleeds are mostly small and submucosal, and operation should be undertaken only as a life-saving measure or because a chronic ulcer is suspected.

Extragastric sources of bleeding must also be excluded before patients are submitted to surgery. The history is most valuable in achieving a correct diagnosis; thus where chronic peptic ulceration is responsible for the bleeding it will be unusual to find such a patient denying previous periodic dyspepsia with relief of his pain by food and alkalis. The shorter the history of preceding dyspepsia, the more likely is the lesion to be acute and therefore susceptible to cure by medical means alone. Unfortunately the diagnosis is not always obvious and the history often misleading.

An attempt to obtain diagnostic information in the acute stages of illness can be helpful in subsequent management, for if chronic peptic ulcer can be diagnosed with confidence surgical treatment is to be recommended for patients over the age of 50 in whom bleeding continues or recurs. The success of such

a selective surgical policy has been shown by its favourable influence on overall mortality (which can be reduced to about 4%), and the prompt submission of suitable patients to operation is almost certainly an important factor in achieving the best results.

Early barium-meal examination has been adopted in some centres as a means of obtaining useful information. The procedure can be undertaken on the ward using a portable x-ray set and without manipulation or the need to move the patient from his bed. Combined with gastroscopy or the use of the fibroscope or gastro-camera it has proved possible to achieve a correct diagnosis of the cause of bleeding in about 80% of patients admitted with haemorrhage from peptic ulcer, usually within 24 or 36 hours from admission. The introduction of the fibroscope or the blind use of the gastro-camera has further

minimized the interference and discomfort suffered by the patient, for, unlike gastroscopy, the procedures can be undertaken on the ward and are far less disturbing.

The importance of reaching an early decision as to the surgical treatment of haematemesis cannot be overemphasized; nevertheless, if it is decided to operate, a little time may be allowed to improve the patient's condition by blood transfusion unless bleeding is so profuse as to permit no delay. Chronic gastric ulcer is a particularly strong indication for surgery; bleeding from this source carries a high mortality under medical treatment and its operative arrest by gastrectomy is generally easier than is the surgery of bleeding duodenal ulcer. The indications for surgical intervention in haematemesis and the treatment of bleeding oesophageal varices will be discussed in further contributions to this series.

TODAY'S DRUGS

With the help of expert contributors we publish below notes on a selection of drugs in current use.

Epsilon Aminocaproic Acid

Epsilon aminocaproic acid (E.A.C.A.), marketed by Kabi Pharmaceuticals Ltd. under the name of Epsikapron, is a potent synthetic inhibitor of fibrinolysis. It is used in the treatment of haemorrhagic states.

Chemistry and Pharmacology

E.A.C.A. is a monoamino carboxylic acid structurally related to lysine; its full inhibitory action is dependent on the epsilon position of the amino group. It does not occur naturally but is synthesized as a white crystalline substance, freely soluble in water, with a molecular weight of 131.

E.A.C.A. inhibits the activators which convert the inactive globulin plasminogen into plasmin, the enzyme which normally digests fibrin. At concentrations greater than 10^{-4} M. E.A.C.A. competes with the activators for the enzyme-binding sites of the plasminogen molecule.¹ Weak non-competitive inhibition of plasmin occurs only after a hundredfold increase of concentration, and even then no effect is apparent on blood coagulation or platelet aggregation.

Clinically significant effects are seen with a plasma E.A.C.A. concentration of 10^{-3} M.; this can be produced by a dosage of 0.1 g./kg. body weight given either orally or intravenously every four hours.²

E.A.C.A. is absorbed rapidly from the gut with peak plasma levels two hours after a single oral dose. The drug is distributed throughout the body water, freely entering the intracellular compartment. The half-life in plasma after a single intravenous injection is of the order of one to three hours; continuous infusion is therefore necessary to maintain adequate blood levels by the intravenous route. Excretion is almost entirely via the kidney, and within 12 hours of a single oral dose 60% to 90% appears unchanged in the urine.²

Clinical Indications

The use of E.A.C.A. should be considered when bleeding cannot be controlled by conventional procedures.

Coagulation Disorders, including Haemophilia.—Whenever fibrin formation is deficient, inhibition of even the normal

fibrinolytic process may preserve sufficient fibrin to permit adequate haemostasis. The use of E.A.C.A. need not therefore be confined to those cases in which an increase in fibrinolysis can be demonstrated.

In haemophilia treatment with E.A.C.A. has been shown to reduce bleeding after tooth extraction.³ Patients under treatment with anticoagulants, and patients with von Willebrand's disease, have also been successfully treated, both for tooth extractions and for menorrhagia.

These examples are concerned with bleeding to the exterior. E.A.C.A. may be just as effective in the control of internal bleeding, but great care in the evacuation of blood clot from the body cavities is necessary if residual damage due to formation of fibrous tissue is to be avoided. In cases of haematuria successful results have been claimed, but urinary obstruction is known to be a possibility, and the incidence of this complication has yet to be defined.

E.A.C.A. has also been used in double-blind trials to test its efficacy in reducing the incidence of spontaneous bleeding episodes in haemophilia.⁴ Early results are promising but not yet conclusive.

Menorrhagia.—The concentration of plasminogen activators in the endometrium is high and increases as menstruation approaches to reach a maximum on the first day of the period. Double-blind trials have shown that inhibition of fibrinolysis reduces the volume of menstrual flow.⁵ If curettage has excluded organic lesions of the uterus and endometrium treatment with E.A.C.A. may be useful for those patients who wish to preserve fertility, especially if hormone therapy has failed or is contraindicated. The drug need be started only when bleeding becomes heavy and need be continued only so long as the flow lasts.

Prostatectomy.—Several trials have shown that the blood loss after prostatectomy can be reduced by giving low doses of E.A.C.A.⁶ The incidence of thrombotic complications in the postoperative period is not affected by E.A.C.A. alone. However, a considerable reduction in pulmonary embolic complications has been achieved by the routine prophylactic administration of heparin, made possible by the simultaneous use of E.A.C.A.⁷

Hyperfibrinolysis.—Excessive amounts of plasminogen activators in the blood may provoke bleeding by the release of plasmin in amounts which overwhelm the natural antiplasmins and attack essential clotting factors, reducing their concentration and blocking fibrin formation still further by the anticoagulant effects of the split products of fibrinogen. In these

circumstances E.A.C.A. is one of the ideal treatments, but primary hyperfibrinolysis is difficult to distinguish from other causes of the defibrination syndrome. It is probably rare unless activators such as streptokinase or urokinase are being deliberately administered as a part of thrombolytic therapy.

Defibrination Syndrome.—In complicated obstetrics, major surgical operations, and disseminated cancer massive bleeding may occur suddenly after widespread intravascular clotting has depleted the available clotting factors.⁸ A common secondary phenomenon in these cases is an increase in fibrinolysis, which is likely to have a protective effect. For this reason when a low level of circulating fibrinogen is demonstrated E.A.C.A. is probably best held in reserve.

Treatment should begin with controlled replacement of fibrinogen and other missing factors, including platelets. If the stimulus to defibrination persists and bleeding continues heparin may be used as an anticoagulant; once the stimulus to clot formation has been controlled in this way E.A.C.A. may assist haemostasis by preventing the removal of fibrin.⁹

Other Uses.—The list of examples in which E.A.C.A. may be used to assist haemostasis is not exclusive. Other suggested uses include epistaxis, ulcerative colitis, and haematemesis; precise indications have yet to be defined.

An anti-allergic action has been attributed to the drug, which has been said to provide improvement in progressive systemic sclerosis and in eczema.¹⁰ Experimental results are conflicting, and the clinical impressions do not stem from organized trials.

Toxicity and Side-effects

Non-thrombotic.—One large carefully investigated series reports the administration of the drug to 774 patients without serious toxicity.¹¹ Minor side-effects include nasal congestion, conjunctival suffusion, nausea, vomiting, diarrhoea, maculopapular rashes, and transient hypotension.

Daily injection into pregnant rats has been reported to cause teratogenic effects in the embryos.¹² Although more recent work failed to confirm this finding,¹³ E.A.C.A. should not be given in the early stages of pregnancy until further studies are available. E.A.C.A. also inhibits the incorporation of lysine into the proteins of a rat diaphragm preparation,² and may slow the growth rate of rats given 100 mg. daily.¹⁴ For these reasons prolonged administration should be avoided during the active growth period of childhood.

High doses have been reported to cause subendocardial haemorrhages in dogs,¹⁰ but no such lesion has been described in man. The intravenous administration of 5 g. of E.A.C.A. per hour, a fivefold increase of the usual dose, causes a small (about 5%) decrease in systolic and diastolic blood pressure, together with a bradycardia, but without any significant change in renal blood flow or glomerular filtration rate.¹⁵ No electrocardiographic changes have been noted. One patient has been reported,¹⁶ who died 32 days after being given E.A.C.A. to control a haemorrhagic state associated with prostatic carcinoma. At necropsy scattered areas of necrosis were found in heart and liver, but their cause was not clear.

Thrombotic.—Fibrin is necessary to promote haemostasis or repair, but once its immediate purpose has been accomplished it must be removed by the fibrinolytic system, normally in dynamic equilibrium with the coagulation system. Undesirable effects may occur if the balance is disturbed by the administration of E.A.C.A., so that removal of fibrin is prevented.

Fibrin formed from blood within a body cavity may remain to become organized into fibrous tissue. In the pleural space this may form a rigid coating surrounding the lung.¹⁰ Similar persistence of clot within a joint cavity may potentiate residual damage to the joint. If clotting occurs in the urinary passages during treatment of haematuria with E.A.C.A. the indestructible

clots may cause permanent obstruction to the urinary outflow tract.⁶

Widespread intravascular fibrin formation is a feature of the defibrination syndrome and also of the later phases of shock. In most of these cases plasminogen activators are released which stimulate endogenous fibrinolysis. If this protective effect is blocked by E.A.C.A. widespread persistence of intravascular thrombi may have fatal results. Examples of such a condition have been found in experimental animals and in man.¹⁷

Presentation and Dose

For oral use there are sachets of effervescent powder, each containing 3 g. of E.A.C.A. There is also a 30% w/v syrup.

For intravenous use, or local application, a 40% w/v solution may be given diluted at least fourfold in physiological saline or glucose solution.

The usual dose, oral or intravenous, is 0.1 g./kg. body weight repeated every four hours. Intravenous administration is started by giving the calculated dose in 30 minutes, followed by a sustaining infusion. Dosage should be reduced if renal function is impaired. As the drug is concentrated in the urine, 3 g. of E.A.C.A. by mouth every eight hours is sufficient to maintain urinary activity in the adult.

There is no contraindication to the simultaneous administration of heparin or oral anticoagulants.

E.A.C.A. is available as Epsikapron. The basic N.H.S. price of 30 sachets of 3 g. is 39s. 10d., and of 250 ml. of 30% syrup is 35s.

ANY QUESTIONS?

We publish below a selection of questions and answers of general interest.

Transmission of Rays through Glass

Q.—*Is there any form of window glass which permits the passage of a large proportion of ultra-violet rays?*

A.—Almost all of the biological actions of ultra-violet radiation occur at wavelengths below 3,100 Å. Ordinary window glass transmits very little below this limit. Special glasses with better transmitting properties were developed during the 1920s. The heavy absorption of ultra-violet rays by glass is associated with the presence of small amounts of ferric oxide. Vita glass differs from common window glass mainly by the addition of a small proportion of boric oxide and the careful exclusion of iron oxide.

The manufacture of Vita glass ceased in Britain some 30 years ago, though the material is still available in the United States. No other window glass with enhanced transmission in the ultra-violet region is currently being made in Britain. The daily amount of ultra-violet rays received at most points in a normal building, even if its windows are glazed with Vita glass, is very small—seldom more than would be obtained by spending a few minutes out of doors in the middle of the day.

Transmission of Abnormalities by Homozygotes

Q.—*A marriage of first cousins produced a healthy boy and a healthy girl. Each of these has married, and the boy has two girls, one of whom has a mitral murmur and the other has syndactylia, webbing of the second and third toes of each foot, and band amputation of the terminal phalanges of all fingers. The girl has a daughter who has been diagnosed as suffering from Turner's syndrome, and has abnormal feet and hands, wide chest, and webbed neck. To what extent is the first-cousin relationship of the grandparents responsible for these congenital abnormalities?*

A.—It is unlikely that the grandparental-cousin marriage is in any way responsible for the varied congenital malformations in the grandchildren. There is at present no evidence that increased homozygosity in a parent leads to an increased risk of chromosomal or other congenital abnormalities in the children.

Effectiveness of A.T.S.

Q.—*Is the effectiveness of antitetanus serum in preventing tetanus lessened in proportion to the length of time after the injury when it is first given?*

A.—To be effective, antitetanus serum must be given in sufficient quantities to ensure that the subject at risk has a protective level of circulating antitoxin at the time tetanus spores start germinating and producing toxin. After administration of 1,500 I.U. A.T.S. the blood antitoxin titre rises to a maximum within one to three days but

then steadily falls to below protective levels within two to three weeks. A longer period of passive immunity is obtained with human tetanus immunoglobulin.

The incubation period of tetanus in man is usually 5 to 14 days but can vary from 3 days to 5 weeks. A.T.S. given within 24 hours of injury should therefore protect against all tetanus infections except those with a long incubation period. If its administration is delayed toxin may have already been formed in cases with a short incubation period. Once formed it is rapidly fixed by the tissues and cannot be neutralized by subsequent injections of antitoxin. It is for these reasons that the effectiveness of tetanus prophylaxis is related to the interval between injury and administration of serum.

Oral Poliomyelitis Vaccine

Q.—*Should a dose of oral poliomyelitis vaccine be repeated when vomiting occurs after its administration? What sort of interval from administration to vomit must elapse for it to be unnecessary to repeat the dose?*

A.—Oral poliomyelitis vaccine (O.P.V.) consists of attenuated strains of the three types of poliovirus. When taken by mouth they can infect and multiply in the alimentary canal, producing antibodies and intestinal resistance to reinfection with the same type poliovirus. A dose between 100,000 and 1 million particles of the different types is the least amount of virus required to immunize consistently, allowing for wastage and individual resistance. Since infection with one type may interfere with another, the vaccine is fed three times at intervals of at least four weeks, thus giving each type three separate opportunities to infect the intestines.

If vomiting occurs immediately after O.P.V. is given the retained amount of each type of poliovirus may be insufficient to give rise to infection and multiplication in the intestines. A supplementary dose should therefore be given at the time to compensate for the amount lost, but if a few minutes elapse before vomiting occurs there is no need to repeat the dose.

Baldness in Women

Q.—*Is punch-grafting of hair-bearing skin a feasible treatment for baldness in women? What other treatment might there be for severely thinned, greasy hair in a middle-aged woman?*

A.—Punch-grafting has been developed essentially for male-type patterned baldness, in which there is a vigorous growth of hair on the back and sides of the scalp and more or less complete baldness in the vertex and frontal region. Punch grafts are taken from the hair-bearing area and arranged along the frontal margin of the scalp so as to blend with a wig. Occasionally it may be possible for sufficient hair to be produced in this way for a wig to be unnecessary. Punch-grafting is not often likely to be satisfactory treatment

in women because the loss of hair is likely to be only partial and probably more diffuse.

Severely thin, greasy hair in a middle-aged woman may result from a wide variety of causes. First it is necessary to ascertain that the thinning of hair is not due to brittleness. When it is broken hairs can easily be seen over the scalp, and the condition may be traced to injudicious hairdressing treatments such as waving, bleaching, etc. More diffuse falling of hair may result from inflammatory conditions of the scalp, particularly seborrhoeic dermatitis. Thinning of the hair of the scalp at the time of the menopause and soon after is so common as to be virtually physiological. Treatment is ineffective.

A diffuse falling of hair may also result from iron deficiency, even in cases where there is no anaemia. It may be dietary in origin or may be the result of deficient absorption of iron. Because of this, a complaint of diffuse falling out of hair without ascertainable cause is often taken as an indication for oral iron therapy for at least a period of a few months. Various types of endocrine disorder may result in diffuse thinning of the hair, and sometimes it is the first sign of an insidious endocrine disorder. In recent years attention has particularly been directed to thyroid diseases, and even when there are no other clinical signs of hypothyroidism or hyperthyroidism laboratory tests should be carried out.

The results of various investigations will indicate treatment. At all times, however, the patient should be cautioned against over-vigorous local treatment. It is suspected that shampooing two or three times a week may in itself promote greasiness and possibly falling of hair. Energetic massage may also do more harm than good. Unless there is a clearly recognized underlying local condition any local treatment is likely to be ineffective.

Inhalation of Iron Dust

Q.—*Is there a medical indication for exhaust-extraction of dust when large cast-iron castings are being turned on a lathe? Some lathes doing this work seem to be fitted with means of extraction and others not.*

A.—It is assumed that the cast-iron castings referred to have been cleaned and that the dust which may arise during lathe-turning will be iron dust free from silica and other dusts which are known to cause fibrosis of the lungs. Though iron dust does not cause fibrosis, it is radio-opaque and will produce changes in a chest x-ray. It is desirable to prevent inhalation of any dust by applying suitable local exhaust ventilation.

Arctic Spray

Q.—*What safety precautions should plumbers take when using Arctic Spray, which consists of dichlorodifluoromethane, for freezing small-bore water pipes, bearing in mind that the majority of plumbing repairs are carried out with the operator working in a restricted space, about 2 ft. (61 cm.) below ground level?*

A.—The freons, of which dichlorodifluoromethane is an example, are chemically inert and non-toxic. Their accepted threshold limit value is 1,000 p.p.m.

NEW APPLIANCES

Peritoneal Dialysis with In-line Sterilization of Dialysate by Filtration

Dr. P. SHARPSTONE, lecturer in medicine, King's College Hospital Medical School, London S.E.5, and Dr. F. S. GOLDBY, medical registrar, King's College Hospital, London S.E.5, write: Peritoneal dialysis by means of commercially prepared solutions and disposable giving sets (Maxwell *et al.*, 1959) is a simple and effective technique, and is in general use in the management of renal failure and sometimes for the correction of overhydration. Disadvantages inherent in this system, however, include the high cost of the dialysate and the risk of introducing infection during the repeated interruption of the fluid pathway in order to change and to make additions to individual 1-litre containers of dialysate. McDonald (1965) has overcome these problems by preparation of dialysate in bulk at the time of use by diluting a concentrated solution with water and sterilizing the final solution by filtration through a 0.22-micron filter during its passage to the patient. He used an automatic peritoneal dialysis machine, but as manual methods of dialysis are more widely used at present we describe here a manually controlled system in which in-line filtration sterilization of the dialysate is used.

METHODS

Five hundred millilitres of a $\times 40$ peritoneal dialysis concentrate (Romford Laboratories Ltd.), 500 to 1,500 ml. of 50% dextrose solution, and potassium, heparin, etc., as required are placed in a 20-litre stainless steel pressure vessel (Millipore (U.K.) Ltd.), which is then filled to a 20-litre internal calibration mark with distilled water. The water is pyrogen-free but unsterilized, and is obtained from the hospital pharmacy in 25-litre polyethylene aspirator bottles. The dialysate is mixed by stirring and its concentration checked by osmometry. The vessel is pressurized by air at 15 lb./sq. in. (1.05 kg./sq. cm.) from a cylinder fitted with 0-30 lb./sq. in. (0-2.1 kg./sq. cm.) regulating valve (British Oxygen Co. Ltd.). Opening the outlet tap of the pressure vessel allows the required exchange volume of dialysate to flow through a 0.22-micron 142-mm. Millipore filter (Millipore (U.K.) Ltd.) into a modified 2-litre polypropylene measuring cylinder (Xlon Products Ltd.) suspended from a transfusion pole 5 ft. (1.5 m.) above the patient (see Diagram). Release of a tubing clamp then allows the dialysate to flow by gravity into the peritoneal cavity through a disposable warming coil (R66 blood warmer, Baxter Laboratories Ltd.) in a thermostatically controlled water bath (JB 1, Grant Instruments (Cambridge) Ltd.). With a bath temperature of 42° C. and a flow rate of 200 ml./min., the dialysate reaches the patient at a temperature of about 33° C.

Disposable vinyl tubing (Portland Plastics Ltd.) is used throughout. After use the pressure vessel and measuring cylinder are thoroughly cleaned and sterilized by autoclaving. The filter holder, after cleaning, is reassembled with a new filter membrane and pre-filter and sterilized in ethylene oxide. Before each dialysis the integrity of the filter

the hospital from a concentrate and distilled water. Sterilization of fluid in large containers is, however, difficult (Bosch *et al.*, 1966) and has led to the adoption of the present technique, which also eliminates the risk, inherent in the conventional method, of introducing infection during the conduct of the dialysis itself. The 0.22-micron filter

Diagram of apparatus for sterilization of dialysate by filtration, and the delivery of measured volumes to the patient via a heating coil.

is confirmed by demonstrating its inability, when wet, to pass air at 25 lb./sq. in. (1.76 kg./sq. cm.).

Animal tests for pyrogens were carried out on samples of dialysate taken from the patient's side of the filter at the end of every third dialysis. Each was given intravenously, in a dose of 3 ml./kg., to three rabbits whose temperatures were monitored for three hours by rectal thermocouples.

RESULTS

Thirty 20- to 40-litre dialyses have been performed with this system. After preparation of the dialysate and apparatus (by medical or specially trained nursing staff) the dialyses were conducted by nurses who required only brief instruction in the technique. Up to 40 litres of dialysate could be exchanged before blockage of the filter membrane necessitated its replacement.

The patients' oral temperatures were recorded two-hourly during dialyses and no pyrexial reactions occurred. All 10 samples of dialysate tested in rabbits were completely free of pyrogenicity.

DISCUSSION

A very considerable saving in dialysis fluid costs is achieved by its bulk preparation in

does not remove pyrogens, but with attention to the cleanliness of the apparatus and the use of pyrogen-free water the dialysate has proved free of pyrogenicity.

Additional advantages of the in-line sterilization system are that the dextrose content and exchange volume of dialysate can be adjusted to the requirements of individual patients; and that as no adjustment of potassium or dextrose content of the dialysate is made during the conduct of the dialysis this may safely be left in the hands of relatively untrained and unsupervised personnel.

We are grateful to Professor J. Anderson and Dr. V. Parsons for permission to treat patients under their care; to Professor A. C. Cunliffe and Dr. A. Dasgupta for help with the bacteriology; and to Dr. D. Gall, of the Wellcome Research Laboratories, for advice and for performing the pyrogen tests. We thank also Mr. J. G. Mulvany, of Millipore (U.K.) Ltd., and Mr. C. H. Chapman, of Grant Instruments (Cambridge) Ltd., for the loan of equipment.

Metabolic Balance Cot for the Newborn Infant

Dr. COLIN H. M. WALKER, consultant paediatrician, Dundee Royal Infirmary and the Department of Child Health, University of Dundee, writes: Techniques for the performance of metabolic balance studies in infants can be divided into two main categories—those in which diaper collection is used (Slater, 1961; Widdowson, 1965) and those in which a special cot with a catchment area is employed (Forfar and Prain, 1950; Barness *et al.*, 1957). A disadvantage of the first method is the risk of loss from a loose diaper or leakage of soft stool past a displaced plastic liner. Balances which require the application of cups (Thomson, 1944) or adhesive bags (Baldwin *et al.*, 1962) have the disadvantages of skin trauma, and constant observation by nursing staff is required to ensure adequate application of the collector. In fact it has been said that "success ultimately depends upon the persistent and personal supervision of the collections by members of the team, who must be prepared to devote a considerable part of their time solely to this aspect of the study" (Stevens *et al.*, 1962).

As medical and nursing staff become more and more difficult to obtain there is a reluctance to ask staff to take part in those metabolic balance studies which might be regarded as yielding useful information yet non-essential to immediate patient-care. For the purpose of performing total metabolic balances of fat and calcium in the newborn an alternative method of collection has therefore been designed.

METABOLIC COT

The cot consists of two main parts which can be used in conjunction with a standard folding crib currently in use in many nurseries (Fig. 1). The outer part consists of a V-shaped catchment which declines to the feet and drains into a funnel at the foot end

FIG. 1.—Metabolic cot assembled without covers.

of the cot. It is made of 0.01-in. (0.25 mm.) transparent polyvinyl chloride plastic and is electronically welded at the edges in such a way that cleaning is not difficult. The inner layer is suspended on a second pair of rods and is a sling of 0.02-in. (0.5-mm.) opaque polyvinyl chloride in which $\frac{3}{8}$ -in. (1-cm.) holes have been punched $\frac{3}{8}$ -in. (1.6-cm.) apart (Fig. 2). The holes are punched in such a way that there is slight embossing with the sharp edge pointing downwards, and though the skin is marked by the holes no injury or

the infants behave normally while nursed on the sling and are fully observable. The assembly is inexpensive, is easily cleaned, and sustains contact with detergent and chemical antiseptics and cleaners. A standard ward cot can be employed and the catchment and sling can be stored in a small space when not in use.

The disadvantages include the need for a temporary napkin collection during breastfeeding, though the advantages remain between whiles. If separate stool and urine

FIG. 2.—Diagram of metabolic cot with dimensions.

irritation occurs over the balance period. This material was selected after other pure plastics and plasticized fibres had been found unsatisfactory because of skin trauma, lack of strength, fraying, or absorption of fluid by fibres.

The cot blanket is encased in non-absorbent plastic and the infant is nursed naked on the sling. The body temperature falls no more than 1° F. (0.55° C.) in a nursery kept at an average temperature of 78° F. (25.6° C.). All excreta either run through the sling on to the catchment or can be washed through. Extra firm stools may be picked off the sling, but as the stool of a newborn infant is usually soft this is seldom necessary. Collection is made into polyethylene bottles continuously mounted below the funnel, and both cot and baby can be swabbed down with deionized water and brush nylon wipes as often as required. The infant is fed in the cot by nurse or mother. During feeding a non-absorbent bib of nylon seersucker is used to catch any regurgitation or vomitus, just as in other study methods, and any wipes used can also be kept in a separate polyethylene bottle for analysis and correction of "intake."

The advantages of this cot are that it allows total collection with minimal handling of the baby and minimal nursing care. The method is fully acceptable by mothers, and

collection is required an adhesive bag technique can be added, and should leakage occur it would probably be more readily noticed in the "open" cot than with a "closed" diaper technique. Occasionally a rather large quantity of deionized water is required for thorough cleansing at the end of the balance study. This makes the analysis more tedious but none the less efficient.

Thanks are expressed to Mr. L. A. McKenzie and Mr. W. Kay, Regional Physics Laboratory, Eastern Regional Hospital Board, Scotland, and Mr. D. M. High, of D. M. High, Waterproof Clothing Manufacturers, Dundee, for their assistance in the construction of this metabolic cot.

This project is supported by a grant from John Wyeth & Brother Ltd.

Book Reviews

Black Magic

The African Witch. With Particular Reference to Witchcraft Beliefs and Practice Among the Shona of Rhodesia. By Michael Gelfand, C.B.E., M.D., F.R.C.P., D.P.H. (Pp. 227+xvi; illustrated. 30s.) Edinburgh and London: E. & S. Livingstone. 1967.

Everyone knows that witches really do exist—especially physicians who practise in the rural areas of Africa. Many, in due course, achieve a harmonious if unofficial working relationship, each recognizing the value of the other, the one for scientific medicine and the other for faith healing. It is indeed only in the mid-nineteenth century, with its great advances in microbiology, biochemistry, and therapeutics that Western medicine has supplemented faith and the apothecary's bottle of medicine with medical science.

In Africa (where animism is prevalent) mysticism and ritual still rule the lives of the majority in the rural areas, and even in the urban areas they still persist, though to a lesser extent. Some two years ago an article appeared in a Nigerian daily newspaper reporting that a small rural retailer whose business was failing consulted a female witch-doctor and allegedly murdered his wife: to produce a brew with certain fats and herbs to boost the business. In Senegal the "marabout" or sorcerer may be both the religious leader and medicine man of his community. Fetishers also undertake dental excisions, incise abscesses, and make simple prosthetics. There are "spirits" for both good and evil. The Kisii in Kenya still trepan certain patients who are possessed of evil spirits giving rise to headaches, mental disturbance, etc., with primitive tools, making a hole to let out the evil spirit. Such is the belief in the powers of witchcraft.

In brief and general terms, many African tribes believe in an all-pervading and prevailing creator who is everywhere, but remote. Lesser spirits, however, more closely related to man's daily activities, exist for both good and evil. The good is the witch-doctor, who, using bones, stones, spells, or potions, removes spells and alleviates sickness. This is the Mganga of the Wakamba. Evil may be accomplished by two methods: either by the ancestral spirit removing his "protection," or by a witch or fetisher (the Mchawi of the Wakamba) casting spells.

The practising physician in Africa, if he is non-African, learns about the inter-relationship of witchcraft and medicine the hard way—by experience. He learns that the African does not believe in Western ideas of the aetiology and epidemiology of disease. He learns that the African consults both types of healer—the physician for the immediate cure of the disease, and the witch doctor for the eradication of the cause. He learns that these are people whose lives are bound by tribal patterns of behaviour, beliefs, and customs. The individual is an integral part of his community, whose thinking tends to be communal, and is subject to many fears and stresses due to transgression of these rules and the attempt to avoid transgression. Add to this the stresses imposed in an attempt to adopt Western concepts and modes of life, and it is little wonder that anxiety states and psychosomatic ills exist. We per-

haps underestimate these strains, the point at which breakdown occurs, and the resort to tribal healers for reassurance.

Michael Gelfand, in his capacity as a trained observer of facts and as a warm human physician with scientific curiosity, has endeavoured to investigate the interface of medicine and witchcraft. This is a book which dissects and displays the anatomy of witchcraft in relation to one particular people of Africa: the Shona of Rhodesia. He describes the people, their culture, and their spiritual beliefs. He describes the types of witches, good and evil, the means they use, the prevalence of witchcraft, and its effect on individuals and communities. He describes the types of illnesses ascribed to witchcraft, the treatment employed, and the results. He examines the place of the witch and the witch-doctor in the daily routine of life.

Perhaps this book is best described as a field-epidemiologist's analysis of witchcraft. It may not be an expert social-anthropologist's bible, but it certainly should be on the shelf of every practising rural physician in Africa. It should rank with his textbooks of tropical medicine and hygiene, to the greater understanding of the afflictions of his patients and community, not to mention the greater understanding by the physician-administrator—for example, page 68 reveals that requests to attend a funeral are not the proverbial facile excuse of the office boy but a serious matter for the African who is absent from the funeral of his relative. In reading this book physicians may begin to understand some of the reasons for the inevitable slowness of change and to remember the old adage—more haste, less speed.

N. R. E. FENDALL.

Sympathetic Amines

The Uptake and Storage of Noradrenaline in Sympathetic Nerves. By Leslie L. Iversen. (Pp. 253+xiii; illustrated. 57s. 6d.) London: Cambridge University Press, 1967.

This is a remarkable book, consisting as it does of a rewritten Ph.D. thesis, and one wishes fervently that more theses had the same potentiality. It consists essentially of two components. The first is a review of the current state of knowledge about uptake and storage of noradrenaline by sympathetic nerves. This is a most valuable review, with a balanced historical outlook, careful selection of references, and a critical approach which does not debar the author from specifying, on particular issues, on which side of the fence he prefers to sit. Possibly the account of xylocholine (parent of today's adrenergic nerve blocking agents) is a little cursory, but this is a small price to pay for such carefully chosen references in general. The second component is the author's own work, particularly his identification in the heart of two uptake mechanisms, handling the

sympathetic amines. His original papers provide a fuller, more rigorous, and indeed more enjoyable account of this work; but the present book allows him to put it into context—to bring out, for instance, the analogies between his Uptake₁ and the uptake-mechanism of the intracellular particles obtained from sympathetic nerve.

The book reflects strongly the present technology of work on the sympathetic system. Most of our best recent knowledge has come through the development of efficient spectrofluorimetry, of tritiated amines with high specific activity, of differential ultracentrifugation, and (most recently) of fluorescence methods applied to amines. As a result, chemistry and biochemistry bulk large, and there is only one record of a physiological experiment illustrated (that of miniature potentials). Those not chemically minded may find their minds clotted by the formidable chemical arrays of amines and related drugs. Yet it is a fact that, once the discovery of reserpine reawakened research on the adrenergic nervous system, it has been the biochemical pharmacologists who have been making the pace. (An awkward conse-

quence of their rate of progress is that the reader must be warned that views have now changed (for instance, about the site of Uptake₂) in a few respects.)

It is an attractive feature of the book that the author himself looks forward to the time when the various transport, binding, and release mechanisms and the subcellular structures are integrated into a functioning unity. The volume can be strongly recommended, with all praise for the care in its production and its compact, efficient index.

W. D. M. PATON.

First Aid

New Essential First Aid. By A. Ward Gardner, M.D., D.I.H., and Peter J. Roylance, M.B., Ch.B. (Pp. 174; illustrated. 3s. 6d.) London: Pan Books. 1967.

This small paperback is the best book on first aid I have read. It is written expressly for the ignorant amateur and throughout emphasizes that the sole function of first aid is to provide the minimum essential treatment to

keep the patient alive and to get him to a doctor or hospital in the best possible condition. In making this point the authors sacrifice a good deal of the minute detail of bandaging, splinting, etc., which is found in most first-aid manuals, but since this book will be bought and used by those who have no particular interest in the subject—for example, road users and householders—nothing is lost thereby.

After a general introduction there is a most important chapter on priorities in first aid. This is a most difficult problem for the layman when, faced with a number of more or less seriously injured people, he has to decide in what order to treat them. In each individual patient, too, it is important to recognize which conditions need urgent treatment and which may be safely left. Obviously each situation must be treated on its merits, but the authors lay down basic principles which any one with average common sense should be able to apply.

Excellent chapters are devoted to mouth-to-nose artificial respiration and unconsciousness. These are followed by sections dealing with bleeding, burns, fractures and dislocations, head injuries, poisoning, and bandaging. A small section on accidental hypothermia is included and there is a very welcome chapter on organizing the first aid at an accident. Most of what the authors say about this is no more than common sense, but this is so often lacking in those trying to help at an incident.

This book should be in every household and in every car. I can recommend it unreservedly.

E. J. CLEGG.

Neuroradiology

Pneumoencephalography. By E. Graeme Robertson, M.D.(Melb.), F.R.C.P., F.R.A.C.P., F.C.R.A.(Hon.). (Pp. 808 + xxiii; illustrated. \$30.50.) Springfield, Illinois: Charles C. Thomas. 1967.

Nearly 30 years ago Graeme Robertson developed the method of controlled fractional encephalography. Gradually his technique has been taken up by neuroradiologists all over the world. Ten years have passed since the first edition of his *Pneumoencephalography* was published; almost immediately it became the bible for workers in this field. With 10 years of added experience, and with his excellent system of documentation, a much-welcome second edition has appeared. The new text is nearly twice the size of the old, and the number of illustrations has been more than doubled. The list of references has lengthened and has been brought up to date.

The author has left most of the old text more or less intact, but many of the chapters have been considerably amplified covering new work. This applies particularly to injuries of the head, developmental anomalies, and encephalography in childhood. Much of the work in the last of these chapters has been facilitated by the use of a special encephalographic paediatric chair developed by his neurosurgeon colleague Mr. R. S. Hooper. From the photographs it looks good and inexpensive.

The most important addition to the work is the long chapter entitled "Comparative Assessment of Pneumoencephalography in

the Investigation of Neoplasms With and Without Increased Pressure." This has been a very vexed question for many years, and it is salutary to see such an authoritative opinion in print. Graeme Robertson is not only a distinguished neurologist but also a neuroradiologist by partial adoption, and his opinion and judgement on this question cannot be lightly dismissed. All medical men concerned with patients suspected of harbouring intracranial tumours will find this chapter of particular interest.

Generally speaking, the reproductions of radiographs are of a high standard, but the publishers might note that some of the pulls from the old blocks are not as good as in the first edition, and one (Fig. 43b) has been reproduced upside down in the new edition (correctly in the first edition). Taking the text as a whole one can find no major faults. The book has become a classic—one can say no more except to look forward to a third edition in another decade.

J. W. D. BULL.

Old People in Our Social Structure

The Social Needs of the Over-80's. The Stockport Survey. By Fraser Brockington, M.A., M.D., B.Chir.(Cantab.), D.P.H., M.R.C.P.(Lond.), M.Sc.(Manch.), and Susanne M. Lempert, M.B., Ch.B., D.P.H. (Pp. 147 + vi. 35s.) Manchester: Manchester University Press. 1966.

The Social Needs of the Over-80's is the report of a survey of all people over 80 years of age in the County Borough of Stockport. When preparing the survey, great difficulty was experienced in identifying the old people. Inquiry from general practitioners, for example, produced only 801 names, whereas it was finally estimated that there were 2,516 persons over 80 years of age in the county borough. This difficulty in finding the aged until their health has completely broken down runs like a thread through the whole book, which becomes an implicit and sometimes explicit plea for preventive care of the aged.

The general characteristics of the aged and the way they fit into the social structure is investigated and analysed under the following headings: sociability, diet, housing, incapacities and illness, mobility, and survival.

To those who have worked with the aged the book brings no surprises, but many impressions are confirmed by factual evidence documented in great detail. This is a healthy exercise because impressions without factual correction often imperceptibly become fantasies and, on occasion, hobby horses. The authors find that the domiciliary services fall short in many aspects in meeting the needs of the over 80s, partly because many old people were unaware of the help available, and partly because the services themselves were sometimes inadequate. They report that prevention as a primary object hardly exists even at such special danger points as leaving hospital or bereavement, and that this failure results in unnecessary admission to institutions.

They conclude that the best hope of improvement lies in a real integration of the existing social and medical services, quoting the authority of the W.H.O. for this, while

accepting the great difficulties which will have to be overcome.

E. WOODFORD-WILLIAMS.

Approaches to Anatomy

An Introduction to Functional Anatomy. 3rd edition. By David Sinclair, M.A., M.D., D.Sc., F.R.C.S.Ed. (Pp. 466; illustrated. 52s. 6d.) Oxford: Blackwell. 1966.

Clinical Anatomy. A Revision and Applied Anatomy for Clinical Students. 3rd edition. By Harold Ellis, M.A., M.Ch., D.M., F.R.C.S. (Pp. 381 + xvi; illustrated. 40s.) Oxford: Blackwell. 1966.

These two books have a different approach to anatomy. Both have now reached their third edition and undoubtedly serve a useful purpose.

Professor Sinclair's book is aimed at the medical ancillary staff who require a basic knowledge not only of anatomical structure but also of elementary physiology of the human body. This new edition has been improved by the addition of much new material, and the chapters on joints and the genitourinary system have been completely rewritten and brought up to date. It gives a concise account of the various tissues and systems of the body and discusses the functional topography of the various organ systems. These different aspects are combined in a very readable and interesting way. The text is well set out and there is a full glossary at the end of the book.

Professor Ellis's book, on the other hand, is essentially a book for medical students and sets out to give the clinical approach to anatomy and highlights those features of anatomy which are of importance in medicine, midwifery, and surgery. The text is particularly suitable for the revision of anatomy during the clinical course and for preparation for final examinations. Although unsuitable as a replacement for the larger textbooks necessary for a student during his initial study of human anatomy, it can serve as a very useful supplement to stimulate the student's interest and to demonstrate the relevance of the subject to clinical practice. The diagrams are simple, numerous, and readily reproducible. The entire text has been revised and many of the illustrations replaced or supplemented.

Both books are more than adequate for the purpose for which they are written and can be recommended without reservation.

W. J. HAMILTON.

"Classic" of Pathology

Recent Advances in Pathology. 8th edition. Edited by C. V. Harrison, M.D. (Pp. 414 + x; illustrated. 70s.) London: J. & A. Churchill. 1966.

This book first appeared in 1932 and since then the appearance of every subsequent edition has been awaited with eagerness. It has always been a great favourite with medical students who had become especially interested in pathology, and some of the chapters of previous editions have become classics. *Recent Advances in Pathology* has always seemed to have a double orientation.

It was directed towards a relatively junior audience, at least as far as pathology was concerned, and was based on a structural or morbid anatomical standpoint. The eighth and latest edition, under the able editorship of Professor C. V. Harrison seems to have retained both these traditions.

The book opens with an outstandingly good account of chromosomal abnormalities in man, by Professor B. Lennox, that will be widely appreciated by students and their teachers. Dr. R. H. Heptinstall's chapter on renal disease rather disappointingly avoids discussion of current views on the pathogenesis of glomerulonephritis, although he does mention Goodpasture's syndrome (apparently inappropriately named, like most eponymous conditions), which now occupies a central position in the controversy on the role of immune complexes in renal pathology. Dr. J. G. Azzopardi contributes a very full account of the systemic effects of neoplasia that is extremely useful, but here again a greater digression into pathogenetic mechanisms would have been appreciated. As might be expected, Professor K. Weinbre's chapter on liver disease is of a high standard and topical. Indeed, the same is true of Professor Harrison's own contributions on lymphoid tissue and arterial disease, and of the chapters by Professor K. A. Porter on tissue transplantation, by Dr. D. Hourihane on malabsorption, and Dr. B. E. Heard on lung disease. There is no doubt the eighth edition of this famous book maintains the tradition of providing an up-to-date account of the structural basis of pathological problems of topical interest.

In view of the book's avowed object it may be unfair to ask for more discussion of pathogenetic mechanisms and inclusion of more material from other disciplines (Professor Porter is a notable exception here) or even ultrastructural data. Much if not most of this experimental material may not stand the test of time. Nevertheless, to paraphrase Sir Thomas Lewis, "it may be exciting, even if untrue," and education and intellectual excitement are inseparable.

W. G. SPECTOR.

Paediatric Cardiology

Heart Disease in Infancy and Childhood. 2nd edition. By John D. Keith, M.D., Richard D. Rowe, M.B.(N.Z.), F.R.C.P. (Edin.), and Peter Vlad, M.D. (Pp. 1239 + xvii; illustrated. £15.) London: Collier-Macmillan. 1967.

The appearance of the second edition of this well-known textbook of paediatric cardiology will be welcomed by all those who are interested in the field. Dr. Keith and his colleagues have substantially revised the first edition and added a number of new chapters. In the preface the authors comment on the continuing need for accurate data on the natural history of heart disorders, despite the fact that surgery has altered the prognosis in so many cardiac lesions.

The book opens with a chapter on the incidence of congenital and rheumatic heart disease, and continues with chapters on heart sounds and murmurs, blood pressure, electrocardiography, oximetry, cardiac catheterization, and angiocardiology. In the chapter on cardiac catheterization special attention is devoted to the risks of the procedure, which are shown to be remarkably small with modern techniques. A chapter on the embryology of congenital heart disease has been contributed by J. W. A. Duckworth, and on the familial occurrence of congenital heart disease by I. Uchida. Chapters then follow on specific lesions, starting with patent ductus arteriosus and working through all congenital anomalies and including important chapters on complete transposition of the great arteries, the dextrocardias, single ventricle, and chamber localization by R. Van Praagh.

The second half of the book is devoted to, in the main, cardiac disorders not of a congenital origin, such as rheumatic heart disease, cardiac involvement in the collagen diseases, bacterial endocarditis, pericarditis, congestive heart failure, the arrhythmias, pulmonary heart disease, atherosclerosis, glycogen storage disease, and other topics. Electrolyte imbalance and the electrocardiogram, and the heart in thyroid disorders and in neuromuscular dystrophies, also receive attention. There is a useful chapter on heart disease

associated with chromosomal abnormalities and on Marfan's syndrome. The final chapters include cardiac tumours, sudden death in infancy and childhood, the heart in anaemia, and cardiac involvement in gargoylism.

In each chapter the subject matter is dealt with exhaustively, the incidence, pathology, physiology, aetiology, diagnosis, treatment, and prognosis being clearly set out. The text is authoritative and detailed without being over-dogmatic, and the very extensive experience of the authors, and in particular of Dr. Keith, is evident from the clarity and decisiveness of the writing. The illustrations are excellent, and there is a good bibliography at the end of each chapter, with a comprehensive index at the end of the book. Every chapter is designed especially to throw light on recent advances—technical, physiological, medical, and surgical.

The book concludes with five appendices on diagnostic problems in angiocardiology, and in cardiac catheterization, clinical problems in congenital heart disease, and, perhaps the most valuable of all, drugs and dosages useful in heart disease in infancy and childhood. Finally, the *tour de force* of the book, Appendix 5, is a tightly condensed summary of all the important features of congenital heart disease arranged as a table.

There is little to criticize in this notable textbook, and it is difficult to pick out any particular part as being better than another. Of special interest to many readers will be the results of the researches of Dr. Keith's associates on the natural history of ventricular septal defect, the incidence of spontaneous closure, and the behaviour of the pulmonary vascular system. Essentially it is a reference book which will inevitably be part of the library of cardiologists and cardiac surgeons, as well as of many general physicians, paediatricians, and research workers in other fields. Withal it is an extremely readable book, owing to the excellence of the writing and the presentation of important data. The authors are to be heartily congratulated on their second edition, which will undoubtedly have a wide appeal and create an extensive demand.

J. F. GOODWIN.

Books Received

Review is not precluded by notice here of books recently received.

Symposium: Thyroid Disease and Calcium Metabolism. Royal College of Physicians of Edinburgh. (Pp. 159; illustrated. 25s.) Edinburgh: R.C.P. 1967.

MEDICAL HISTORY

Queen Elizabeth Hospital for Children, London: Centenary of "The Queen's," 1867-1967

VALENTINE A. J. SWAIN,* F.R.C.S.

Brit. med. J., 1967, 4, 733-735

One hundred years ago the Queen Elizabeth Hospital for Children was established in Bethnal Green by the Misses Mary Elizabeth and Ellen Phillips. Their social conscience was stirred by the terrible scourge of Asiatic cholera in 1866 which spread rapidly through the east of London. This epidemic threw a pitiful light on the way children of the poor lived. In the squalor and overcrowding the sick, ill-clothed, and ill-fed children drew attention to the urgent need for a special hospital. The population of Bethnal Green and Shoreditch was nearly a quarter of a million. In the hospitals' annual report of that time we read: "In the great city of London, which till a few years ago possessed no hospital for children, out of every 100 children 24 die annually during the first 2 years of life, and during the next 8 years 11 die out of the remaining 76. These children perish, not because there is in them (in most cases) any dangerous sickness but for want of sanitary and medical knowledge in respect of their tender lives."

Early Days

In the first part of the nineteenth century the establishment of special hospitals met with opposition, especially in the case of children's hospitals, for many thought that it was essential for the mothers to care for their own children. Florence Nightingale in 1860 wrote that "the causes of the enormous

child mortality are perfectly well known, they are chiefly want of cleanliness, want of ventilation, and want of whitewash: in one word, defective household hygiene."

On 12 July 1867 the Misses Phillips rented a house in Virginia Row, Bethnal Green, and set up the "Dispensary for Women and Children." As the patients so thronged the building, it was decided that children only would be treated. The next year the work was transferred to 125 Hackney Road, near to Shoreditch Church, where in addition 12 cots were provided. Soon this building too became inadequate, and in 1870, with the financial help raised by a bazaar at Cannon Street Hotel, the freehold of 327 Hackney Road (part of the present site of the hospital in Goldsmith Row) was purchased. From this humble beginning the hospital enlarged to its present size. In the early days annual subscribers had the privilege of recommending a number of children as outpatients and/or inpatients in proportion to the amount subscribed. Otherwise the charge of two-pence was made for an outpatient attendance and inpatients paid 2s. 6d. per week. This payment had a salutary effect, permitting genuine cases to be seen, and "upheld the self-respect of people, so that they would not be regarded as paupers." The children had to be brought in the arms of their parents, but when too ill to be so transported nurses visited their homes. In 1898, owing to the large number of the more prosperous parents seeking treatment, an inquiry officer was appointed to check the abuse, and in 1903, with the appointment of Miss Miller Jones, this post became that of lady almoner.

* Senior Surgeon, Queen Elizabeth Hospital for Children, London E.2.

Miss Mary Elizabeth Phillips.

The North-Eastern Hospital for Children, Hackney Road.

Mrs. Alex Fox (née Ellen Phillips).

Raising of Funds

The Phillips sisters were members of the Society of Friends, and likewise the Foundation Committee under the Presidency of Joseph Gurney Barclay consisted of prominent members of that fraternity—William Beck, John D. Fry, J. Lister Godlee, Edmund Pace, and Nathaniel Tregelles. Thus from the beginning the hospital benefited by the benevolent philanthropy, wisdom, and business initiative of this pioneer committee. At first, in 1868, there was only a handful of generous benefactors, but gradually funds were sought for expansion. Bazaars, concerts, and dinners were organized to meet the cost of new buildings. Soon Royal Patrons, Queen Victoria and the Royal Princesses, and civic and ecclesiastical dignitaries graced these efforts. Voluntary subscriptions and funds increased to pay for future projects. City companies, merchants, bankers, and also friends of the hospital contributed, and individual gifts were numerous. In 1877 the Children's Association was established "to promote an interest among children of the upper classes in the welfare of children of the poor, to provide funds for the maintenance of the hospital and to encourage the use of the talents and leisure time of children to benefit the hospital and its patients." Later such funds as the "Stamp Collectors' Fund" started by Mr. Glenton Kerr, the secretary, and the "Little Folk's Fund" did much to spread the name of the hospital abroad. In 1893, through the generous gift of £10,000 by Mr. John Horniman, the building fund was set up. In 1897 a three-day bazaar was held at Queen's Hall to raise funds for the additional building. The Duchess of Connaught, the Duchess of Marlborough, and the Duchess of Newcastle performed the opening ceremonies. Many other distinguished personages and friends took an active interest in the hospital. At the turn of the century H.R.H. Princess Louise opened the new building and 134 beds became available.

Medical and Nursing Staffs

From the beginning the hospital was equally fortunate in having a distinguished medical staff. In 1867 (Sir) Jonathan Hutchinson and (Sir) Morell Mackenzie became the first consulting surgeon and physician respectively, and (Sir) Wilson Fox's name was later added as consulting physician. He was a fellow student of Joseph Lister, and, like Hutchinson, was also a Quaker. These great clinicians introduced promising colleagues to serve on the staff, such as the erudite Dr. William B. Woodham, Dr. A. E. Sansom, and Dr. W. Cayley as physicians. The last two actively served the hospital for 15 years.

The surgeon, Mr. Waren Tay, was appointed in 1868, as a friend and collaborator with Hutchinson; both contributed much to general surgery and ophthalmology. Also the two eponymous diseases, Tay-Sachs disease and Hutchinson's triad, reflect a small part of their wide interest as writers, teachers, and clinicians. They had the distinction in 1871 of being the first to successfully operate on an infant suffering from intussusception. During Waren Tay's 21 years on the staff (Sir) Rickman J. Godlee in 1881 became the second surgeon for the next seven years and consulting surgeon till his death in 1925. Godlee, Joseph Lister's nephew and assistant, "did much to enhance the reputation of the hospital." All these physicians and surgeons were also on the staff of teaching hospitals—the London, University College, or Middlesex. These set the pattern for future years.

The nursing staff was also of high standard. Miss Anne Elizabeth Horne, trained at St. Thomas's Hospital, was the first Lady Superintendent and Matron in 1870. She had "general charge and management of the hospital" and looked after the housekeeping and household accounts and held "the position of mistress of the family." The nurses had to be "able to read as well as write with facility, and each nurse should attend to the children with care and kindness and use every endeavour to make them happy." "The Matron's and Servants' wages" amounted to £117 16s. 8d. a year. On her marriage to Yardley Warner in 1877 Miss Horne went to America to undertake philanthropic work. She was succeeded by Miss E. W. Curno (1877–1902) and Miss Ann Bushby (1902–27). Miss Bushby was trained at the East London Hospital for Children and King's College Hospital; her outstanding interest in children's nursing led to her election to the General Nursing Council, and she was Vice-President of the British College of Nursing. Many of the nurses trained at the hospital became matrons at other children's hospitals and many served overseas.

Specialties

Gradually during the century general medicine and surgery made way for special disciplines, and the hospital kept abreast of medical progress. Though anaesthesia and antiseptic methods were adopted in the hospital in the early days, the scope of surgery was limited at first to opening abscesses, removing necrotic bone, treating injuries and deformities, and an occasional tracheostomy and lithotomy operation. The first "chloroformist," Dr. John Poland, was appointed in 1880; before this the residents were instructed in anaesthesia, and in fact Dr. Sansom, who was a friend of John Snow, in 1865 wrote his book, *Chloroform: Its Action and Administration*. In some hospitals an extra salary was paid to the anaesthetist, but it was not until 1870–80 that the specialist posts were established. Later other specialists followed, for in 1895 Mr. Sydney Stephenson became the first ophthalmologist, and two years later Mr. John W. Pare started a pioneer special dental clinic for children.

In 1898 electric lighting was installed throughout the hospital, and the 7th Duke of Newcastle, who was a Life Governor and later a member of the Management Committee, in the same year presented the gift of the "complete and very powerful Roentgen Rays apparatus." It was to be supervised and examined at the cost of two guineas annually. By this gift the hospital was the first children's hospital to possess such an apparatus. This event was celebrated by a soirée—"plants for decoration, an extra porter, and a band were engaged" for the ceremony.

In 1910, the ear, nose, and throat and the skin departments were started by Mr. W. G. Howarth and Dr. H. G. Adamson. Other specialties followed, so that now most of the special branches of paediatrics are represented.

Before the first world war in 1914 women became eligible for two of the resident medical appointments, and the late Dr.

NEW HOSPITAL FOR CHILDREN AT SHOREDITCH

This morning a fancy bazaar is held at the Cannon-street Hotel, concerning which it may be useful to give a few heads of information. Under the special patronage of their Royal Highnesses the Prince and Princess Christian, the Prince and Princess of Teck, and the Princess Louise, it is to be opened by the latter in person, who, in a certain sense, is acting for the Queen; for her Majesty has taken the deepest interest in the labour in hand, and has contributed personally to the stalls, while the Princess of Wales, the Crown Princess of Prussia, and other members of the Royal Family have sent goods worked by their own hands, or collected by themselves, in the hope of increasing materially the fund on behalf of which the bazaar is held. It is desired to increase the scope of a Children's Hospital, now working in Shoreditch, and her Majesty and family who, as is well known, send annual presents of toys, and in other substantial modes, testify their interest in the excellent establishment in Great Ormond-street, are earnest in their wish to aid the project for which to-day's bazaar is held, in the most direct and unmistakable way. We have just visited the modest little establishment now open, have endeavoured to master the principle upon which it is carried on, and have come away profoundly satisfied that those who show themselves of the Queen's way of thinking by supporting the bazaar to-day will further an institution which is admirable in its

was necessary to limit it to children only. In April, 1868, the present house was taken in 11 Hackney-road, the services of a second medical officer and of a qualified dispenser were procured, and a dispensary opened four days in the week. Before this, it must be understood, a lively interest had been roused in the neighbourhood, and the appointment of an influential committee, and the receipt of handsome donations and subscriptions gradually followed. The good things grew and prospered. The benevolent impulse and constant care of its far founder met with their reward, and in February last year two small wards, containing two beds, were provided, in addition to the out-patients' department, and the new hospital for children was established. It has not yet been able to exceed the limit named, though the little beds are arranged so near to each other as to be almost in contact with sanitary conditions, and though most pitiable cases are pleading for admission within its doors. Up the narrow stairs, and down a light and cheerful bottom on the first floor, where a stout and motherly-looking nurse reigns over her little charges with a loving hand, and where toys and picture-books are being played with and turned over by wee little fellows, who turn a wistful eye to the new comer while such of them as are strong enough ask questions as to their condition and treatment of a grateful smile. They are eminently well behaved. The refining influence of all health is embodied what is coarse and elevated what is tender in their little faces, until no visitor could suppose them to be of other than gentle nurture and blood. We shall again avoid the description of their complaints. Why distress

Excerpt from the *Daily News*, 16 May 1870.

Helen Mackay (paediatrician 1916–59) recalled that the hospital served both “as general practitioner as well as consultant for children miles around.” In the neighbourhood there was still much poverty and undernourishment. Rickets was very common and so also were anaemia and dental caries. Gastro-enteritis then had a death rate of about 50%. “No treatment, other than skilful nursing, was available for very many of the patients in the medical wards.” Between 1920 and 1930 there was a “grim period of unemployment,” after which the living standard gradually rose, and because of better feeding and care the health of children improved. About that time paediatrics became a specialty, and some 25 years later paediatric surgery was established as an entity. In the 1930s additional buildings were completed—Princess Elizabeth Ward (1930) to accommodate infants and nursing mothers; an enlarged dental department, massage and light department (1934); a new outpatient department (1938); and new casualty, pathology, and x-ray departments and observation ward (1939)—thus 160 beds were available in London and 44 beds at Bexhill.

At the outbreak of the second world war the Queen's was designated as a hospital for civilian casualties only, on the assumption that there would be a mass evacuation of all children from London; but gradually the child evacuees returned to East London, and so the children's outpatient and casualty department were reopened. In the Battle of Britain period of 1940 large-scale evacuation of children returned. The sick children of the Queen's Hospital with those from Princess Elizabeth of York, Shadwell, were accommodated at an improvised hospital at Ashendene in Hertfordshire and at Bayford. Both of the main hospitals received their share of the air raids and bombs that fell heavily on East London, but the buildings survived without major damage.

When in 1868 the hospital first moved to Hackney Road it was named the “North-Eastern Hospital for Children,” becoming “The Queen's” in 1908. With the amalgamation in 1942 of the “Princess Elizabeth of York Hospital for Children” (formerly the East London Hospital for Children, Shadwell), the new title the “Queen Elizabeth Hospital for Children” was acquired under the patronage of H.M. the King and H.M. the Queen and H.R.H. Princess Elizabeth. Other branches of the

hospital are the Little Folk's Home at Bexhill (1930) and the country hospital at Banstead, Surrey—a gift from Mr. Stanley Garton—completed in 1948. In 1948, with the National Health Service Act, the hospital became part of the N.E. Metropolitan Regional Hospital Board. In 1963 the Shadwell branch was closed for economic reasons. That hospital, formerly the “East London Hospital for Children,” had a parallel beginning with the Hackney Road branch, but its history is another story. Since 1946 regular postgraduate teaching has been undertaken in association with the Institute of Child Health, and more recently undergraduate students attend for paediatric training.

The Hospital Today

The Queen Elizabeth Hospital today is a busy general children's hospital for acute cases, and with its 270 beds serves the neighbourhood, and by reason of its special interests young patients also come from all parts of the country and overseas. Through the close links with maternity units, many newborn babies are admitted, and their congenital disorders and malformations are a special study in the hospital. The changing pattern of disease in children today shows a large increase in the work among the youngest age groups. The special investigations, techniques, and modern treatment call for increased space and staff. The present and future generation of nurses, doctors, and patients will find encouragement in the very generous support given by the Hayward Foundation to the hospital's Research Appeal Fund for the building of a new diagnostic unit and research laboratories. These new additions will help to keep the hospital in the van of medical progress. Funds are still needed to endow these enterprises. Furthermore, it is hoped that a new operating-theatre suite with an intensive care unit and a new nurses' home, to replace the old residence, will be built, and that perhaps additional wards will be planned by the next decade.

The fulfilment of these plans would be a legacy worthy of those members of the Society of Friends who founded the hospital 100 years ago.

MEDICAL EDUCATION

Training of Nephrologists

Two recent publications^{1,2} have recently appeared dealing with the training of nephrologists. A memorandum¹ by the Renal Association defines nephrology as “the study of renal structure and function in health and disease, including the prevention and treatment of diseases involving the kidney and urinary tract at all ages.” The memorandum envisages two types of renal unit—*major units*, which would serve a population of about 2 million and would usually be situated at teaching or major district hospitals; and *subsidiary units*, which would serve a population of about 200,000, and would preferably be associated with a major unit. The major unit would contain 60 beds, including 10 for intermittent haemodialysis. It would undertake the full management of all types of renal disease, including renal trans-

plantation; the training of nephrologists and urologists; research; and the co-ordination of the subsidiary units in the area. The subsidiary units would be mainly concerned with intermittent haemodialysis.

The staffing envisaged in the memorandum comprises two or three consultant nephrologists; two or three urologists; two or three whole-time senior registrars (one surgical); and six medical registrars/senior house-officers (divided between medicine and surgery). Staff to provide a 24-hour specialist ancillary service would also be necessary.

The report of the Royal College of Physicians' Committee on Nephrology² recommends that nephrology should be recognized as a specialty of medicine. It considers that it will be necessary to provide special training for both nephrologists—that is, consul-

tant physicians almost wholly engaged in the specialty—and general physicians with a special interest in nephrology. The committee suggests that after the pre-registration year nephrologists should spend a year in gaining further experience in a hospital post, or in a laboratory or research post. Thereafter two years should be spent in general clinical medicine at registrar (or equivalent) level, and four years at senior registrar (or equivalent) level, with at least six months' experience in dialysis at some stage of training.

CONFERENCES AND MEETINGS

Exploration of Teaching in General Practice: Conference at R.C.G.P.

[FROM A SPECIAL CORRESPONDENT]

A one-and-a-half-day conference on the exploration of teaching in general practice was held at the Royal College of General Practitioners in London on 8 and 9 December.

Dr. D. L. CROMBIE (general practitioner and Director of the College Records and Statistical Unit, Birmingham), speaking on "The Problems of Teaching in General Practice," said the general practitioner's function was primary assessment of undifferentiated clinical material. A personal doctor practising continuing care, he relied on the assessment of probabilities. Classical teaching of medical students, based on diagnostic procedures suitable for selected hospital cases, was unsuitable for this material, and young general practitioners had to learn appropriate methods when they got into practice. A rational medical education should teach both methods of diagnosis, but would do so only when general practitioners themselves became teachers. The discipline of general practice could become reproducible and transmissible only after research into general practitioners' methods, which should be initiated by academic departments.

Dr. KEITH HODGKIN (general practitioner, Redcar), on "Factual Observations," demonstrated that the clinical material in general practice differed in both quality and quantity from that seen in hospital. Teaching based on hospital material gave a false bias. A survey into acute appendicitis in Newcastle had shown that 49% of children had perforated appendices on admission to hospital because of delay in diagnosis by parents and general practitioners. He showed from figures in his practice that this delay was due to confusion with gastroenteritis: a general practitioner saw about 150 cases per annum, of which one or two had appendicitis. Improvement in diagnosis would come by recognition of this confusion. It could be taught only in general practice because gastroenteritis is not a hospital disease.

View of the Medical School

Professor Sir BRIAN WINDEYER (Dean of the Middlesex Hospital Medical School, London), speaking on "As the Medical School sees the Problem," gave the consensus of opinion in one school, though he said that each school must evolve in its own way. Undergraduate education no longer hoped to produce a complete doctor, but to teach basic knowledge of causation, manifestations, and history of disease, as well as the effects of the behaviour of individuals. In the past the school had concentrated on sick people in hospital and did not teach students enough about the common illnesses dealt with by personal family doctors. These illnesses could be taught in a teaching general practice which was part of a department of social medicine. He questioned the assumption that if students knew more about general practice they would be attracted to it: ultimate careers depended on circumstance, though personalities among

teachers could motivate students towards their particular branch of medicine.

Dr. IAN McWHINNEY (general practitioner, Stratford-on-Avon) said that general practice dealt with clinical decisions about individuals, and social medicine with epidemiology and the medical care of communities. The general practitioner must know about epidemiology and sociology, but his discipline lay between social and clinical medicine. It should be taught in a department which was separate from, though closely linked with, a department of social medicine.

The chairman, Professor Sir MAX ROSENHEIM, P.R.C.P., summing up the morning session, said that undergraduate education gave students a good basic training and a critical attitude to innovation. The conference should, in his opinion, concentrate on vocational training, for which Dr. Hodgkin's paper seemed to him an impassioned plea.

Present Teaching in General Practice

With Dr. John Hunt, President of the Royal College of General Practitioners, in the chair at the afternoon session, Dr. ANDREW SMITH (general practitioner and clinical tutor in family medicine at Newcastle upon Tyne University) discussed "Present Teaching in General Practice." He described the family and community medicine course at Newcastle, which involved all students in their first clinical year for five weeks, half of which was spent in general practice with one of 12 clinical tutors (general practitioners working in partnership or group practice) and half in community medicine with district nurses, health visitors, and other community workers. The content of the course evolved at regular meetings of the teaching group, which included six senior consultants as well as the general practitioners and public health doctors. The teaching general practices were organized so that the tutor could devote time to teaching undistracted by routine work. The course had been conspicuously successful in that students are matured by their experience in general practice and had asked for and been given an extra week of it. Another test of success, an increase in the number of students who wanted to enter general practice, had yet to be faced.

Professor RICHARD SCOTT (professor of general practice at the University of Edinburgh) said that general practice was an integral part of a community health service in that it offered everyone direct and continuing access to a doctor. Its major activity was application of existing knowledge, and everything in the undergraduate curriculum was relevant to it. It should be taught by involving students in delegated clinical responsibility at the patient's home or the general practitioner's consulting-room. Some of the resources of general practice might contribute to a division of community medicine in a medical school, and he cited

as an example how a medical student could become involved in obstetrics by questioning the expectant mother about her own and her family's emotional attitude to her pregnancy and listening to her replies.

Clinical Content

Dr. P. S. BYRNE (general practitioner and lecturer in general practice at Manchester University) discussed "The Clinical Content of General Practice." The need for definition became apparent when the National Health Service divorced general practice from hospital medicine and medical knowledge advanced so rapidly. General practice had become a discipline in its own right and research was needed to discover both its present content and its projection into the future. The general practitioner was a generalist and his skills were sharpest in conditions which did not need hospital techniques.

Dr. Byrne saw the general practitioner as the general physician of the future who would practise in groups and develop a medical hobby. Academic departments of general practice were needed to define clinical content, and to teach the continuing advances which had changed many diseases from hospital to domiciliary ones.

Professor J. C. VAN ES (professor of general practice at the University of Utrecht, Holland) described the new curriculum at his medical school, now in its third year. General practice was taught to all third-year students. There were lectures on topics such as the doctor-patient relationship and the morbidity patterns in general practice. Each student was attached to a general practitioner, when he studied in detail the non-clinical impact of illness on specific families. Clinical aspects were demonstrated in the final year, when students accompanied general practitioners on urgent visits. Specific training for the expected 70-80 would-be general practitioners was planned after graduation and was expected to take one year, though experience might show that a longer period was necessary.

Professor JOHN ANDERSON (professor of medicine, King's College Hospital, London) spoke on the "Role of the Universities in General Practice." In his view, though the universities aimed to teach students the importance of flexibility and change, they were themselves bound by the traditions of the Middle Ages. The whole medical curriculum ought to be changed. Medicine was dominated by science to the exclusion of psychology and sociology; dissecting animals was irrelevant to understanding human behaviour, and anatomical diagnosis to solving problems. Old rituals needed to be discarded in favour of new attitudes based on the doctor's role in society. Medicine was the most conservative profession, and nowhere more so than in the University of London, where Oxbridge amateurism and dilettantism obstructed reform.

Application of Teaching Methods

On 9 December, with Professor H. W. ROBSON (Vice Chancellor, Sheffield University) in the chair, Mr. A. E. TUBBS (Department of Education, University of Birmingham) spoke on "The Application of Teaching Methods." The general practitioner's work, he said, differed from that of other doctors in that he was concerned with patients—the detection of departures from normal, long-term management, and emotional problems—rather than with disease. Learning should include discrimination and explaining situations, as well as acquiring skills and retaining originality. It was likely to occur best in small groups in which the learners played an active part and there was an adequate system of feed-back. Objectives of teaching must be clear and feed-back must occur quickly enough to allow modification of teaching methods.

Dr. J. R. ELLIS (honorary secretary of the Association for the Study of Medical Education) spoke about "Future Teaching of General Practice." There would, he said, be enormous changes in general practice in the next decade. The increasing gap between demand and supply would force general practitioners into groups, where delegation of work was easier. He would need 10 years' training, half of which would be under-

graduate and half vocational. Vocational training would be done more efficiently in hospital than in general practice itself because human behaviour, of the relatives as well as the patients themselves, was concentrated there. The general practitioner was mistaken in thinking he knew the community: he dealt with only a selected section of it.

Dr. J. R. REVANS (senior administrative medical officer, Wessex Regional Hospital Board) dealt with "General Practice and the Hospitals." He said that general practitioners needed continuing postgraduate education, and described the Wessex facilities, which included a postgraduate dean, a medical centre, and a library. He thought that cottage hospitals should be converted into health centres with preconvalescent beds and facilities for minor surgery. General practitioners must play a part in the whole of medical care, perhaps through general-practitioner beds in district hospitals as well as clinical assistantships.

Dr. W. KERR HENDERSON (senior medical officer, Department of Health for Scotland) said that teaching health centres could achieve some of the objectives outlined. They could provide material for the teaching of community medicine which was suitable for both undergraduates and postgraduates and would be the natural location for a department of community medicine. They

should be closely associated with the teaching hospital.

Dr. GEORGE SWIFT (Chairman of Council of the Royal College of General Practitioners and general practitioner, Winchester) spoke about vocational training, of which he thought a general practitioner needed a minimum of three years—two in hospital and one in general practice. He estimated that 940 new entrants to general practice were needed each year, and suggested that some should be married women at present employed as assistant county medical officers, who would need vocational training. Recruitment to vocational training was at present exceptionally poor because untrained young doctors could earn twice as much in general practice. A national policy was needed in which vocational training would be an essential prerequisite to becoming a principal in general practice, and the General Medical Council and the Ministry of Health should initiate it.

Summing up the conference, Professor H. N. ROBSON said that nobody was satisfied with the present education of doctors. It must be improved by the inclusion of the body of knowledge of the undifferentiated mass of human discomfort and illness in the community. In his opinion this should be taught in a department of general medicine, headed by a generalist with a background of general practice and community medicine.

Mathematics in Medicine: B.M.A. Symposium

A symposium on the application of mathematical and computer methods to problems in medicine was held under the joint auspices of the British Medical Association and the Institute of Mathematics at B.M.A. House on 6 December.

The chairman for the morning session, Dr. RONALD GIBSON (Chairman of the B.M.A. Council), introduced Dr. BRIAN THWAITES (President of the Institute of Mathematics and Principal of Westfield College). Dr. Thwaites spoke of the difficulties involved in the analysis of data, taking aortic blood flow as an example. The medical profession was prone to force data to fit into some kind of linear relationship, commonly by using logarithms. Nevertheless, the restriction and categorization of data often allowed more useful relationships to be shown than those resulting from indeterminate selection. Finally, he drew attention to the difficulty of mathematical predictions in a biological system owing to the enormous number of variations that could be introduced.

Dr. PERCY CLIFFE (Westminster Hospital, London) expressed concern with the lack of mathematical knowledge among doctors. He illustrated the value of mathematical models with some examples of varying complexity. The measurement of the coronary blood flow by an infusion technique was compared to a simple inflow-outflow system, and he also described the predictions obtained from a model of the control of schistosomiasis, which were accurate even in assessing the lack of control during the second world war.

Biological Wave Forms

Dr. H. R. A. TOWNSEND (Western General Hospital, Edinburgh) spoke on wave forms of biological origin. The simplest observations were those made on unit potentials where a series of events could be observed during the course of a base-line tracing. The number and sequence were analysed, grouped, and an attempt was made to determine their relation to other phenomena. Data were presented graphically, and it was often necessary to transform them in order to obtain linear relationships. In the electrocardiogram the waveform was evidently related to the underlying physiology of the heart, and quantitative measurements could be derived from it. In the electroencephalogram, on the other hand, irregular waves were produced, and the unaided human eye could pick out only outstanding features—for example, the specific changes associated with epilepsy. Mathematical transformation into more regular waveforms would enable further understanding and prediction of future events in the electroencephalogram.

Mr. J. E. HAILSTONE (Atlas Computers) gave a warning of the difficult task of analysing waveforms. A clearly defined account could not be made even by mathematicians.

With Dr. Thwaites in the chair, at the afternoon session Professor J. ANDERSON (King's College Hospital, London) opened by pointing out that the new vocabulary facing the medical student fresh from strictly

scientific disciplines had not sufficiently interested the medical teacher. Not only did they have to learn a new terminology but also the process of reorientation. Clearly the process was without end. Already the number of articles published had outstripped the capacity of the individual doctor even to select the worth-while topics for study. Nevertheless, the use of a computer as the store and devices such as "key words" in articles would enable an adequate survey of the world literature to be carried out. A source of confusion was that the many syndromes and synonyms might cause "noise," but this could be remedied by careful selection of headings and careful definition of terms. There was a special need for doctors' thoughts and opinions to be speedily transferred into a permanent record.

In the discussion one speaker emphasized that a computer only recodified thoughts from one language to another. Problems arose from the alternative meanings which were prevalent in medicine. Dr. Townsend produced a list of 300 words used in electroencephalographic terminology, but considered that another 700 would cover most situations.

Use in Diagnosis

Professor PAUL HALL (Karolinska Hospital, Stockholm, Sweden) began with a warning, saying that he considered "automated medical diagnosis" to be a misnomer. On the one hand, the diagnosis proper corre-

sponded to the definition of disease. On the other hand, the computer gave rise to a statistician's probability diagnosis. At his hospital they had obtained 10 years' experience. The computer system allowed for a central library which contained all records. This had solved the difficulty of inadequate and slow retrieval of information. Search was made for cases with similar symptoms, signs, and progress; thus the diagnosis, therapy, and prognosis could be used as a guide for new cases. In 1962 they had introduced a standardized questionnaire to be completed by patients, and they had also been greatly helped by a new type of aide, who was both a secretary and a computer operator. Professor Hall emphasized that they had avoided making doctors into computer technicians. Once the questionnaire was completed a summary was prepared; the doctor then obtained

any other details required and proceeded to physical examination and the relevant ancillary investigations. It had been found that effective action could be taken as a result of the questionnaire alone in up to 85% of the cases. The essential role of the computer was to store information and to allow its rapid retrieval. The cost of the new system was twice as much as with the conventional methods, but the saving in time was about 60 times.

Professor G. A. BARNARD (University of Essex) spoke of an impressive questionnaire he had seen used in an allergy clinic in Wisconsin. The patients sat in front of the computer and answered a series of questions by pressing the appropriate buttons on the machine. The output of the machine was presented in the form of an abbreviated medical history. This had led to speeding

up of the diagnostic service. Professor W. J. H. BUTTERFIELD (Guy's Hospital, London) said that he was worried that this extreme form of mechanization would not be comprehensible to the less intelligent patients.

Discussing the problems of storage and data retrieval of information, Dr. J. HOWLETT (Science Research Council's Atlas Computer Laboratory) said that the retrieval of literature was aided by the use of "key words" in articles. There was no real need to learn computer language, for an understanding of the process was sufficient. Problems were more likely to arise in insufficiently restricting the computer, with the possible result of a deluge of unwanted data. He demonstrated the use of a computer in producing a 10-foot roll of references to the work of an author and the author himself.

Current Trends in Epilepsy

[FROM A SPECIAL CORRESPONDENT]

Opening the British Epilepsy Association's symposium on current trends, held in Manchester on 25 November, the chairman, LORD COHEN OF BIRKENHEAD, introduced the first speaker, Dr. JOHN HUNT (London), whom he congratulated upon his recent election as President of the Royal College of General Practitioners.

Dr. Hunt spoke from the viewpoint of the family doctor and emphasized the widely differing forms taken by epileptic attacks. One type of special interest was the convulsive epileptiform fit sometimes seen during vasovagal fainting attacks. Such fits were due to cerebral ischaemia and used to be regarded as unmasking an epileptic tendency, but many people now thought that cerebral ischaemia was just one of a number of factors able to induce epileptiform convulsions in normal subjects. If full investigation revealed no evidence of idiopathic epilepsy, such patients could lead a normal life avoiding known precipitating factors.

Continuing, Dr. Hunt pointed out that practitioners seldom witnessed single fits, but their presence was often vital in serial attacks or status epilepticus, when maintenance of an airway, assisted respiration when necessary, and intramuscular injection of an anti-convulsant could be life-saving. Between attacks treatment had to be scrupulously regular, and the practitioner's task was to exert a stabilizing, common-sense influence and ensure that his patients received the best possible education and employment. Restrictions should be kept to a minimum, for everyone had to be prepared to accept some degree of calculated risk. Patients with epilepsy who wished to marry should always reveal their true condition before becoming engaged, but there was only a slight possibility that children would be affected.

Temporal Lobe Epilepsy

Speaking on temporal lobe epilepsy, Dr. MAURICE PARSONAGE (Leeds) outlined earlier studies of its natural history and gave preliminary results of a follow-up study being carried out in Leeds. Among 103

patients with temporal lobe epilepsy—the commonest single variety seen in clinical practice—the aetiology was uncertain in 60; 12 had cerebrovascular disease, 10 tumours, and six a history of trauma. Other less common causes were degenerative disease, post-infective or infantile brain damage, and neurosyphilis. Fourteen patients had remissions, probably unrelated to treatment, lasting for periods ranging from three to 25 years. In general, the results of therapy were disappointing; drug treatment, mainly with phenytoin, controlled fits in only 45%, while elective lobectomy reduced rather than abolished attacks in three out of the four patients submitted to the operation.

About two-thirds of the patients in Dr. Parsonage's series had personality changes—depression in 42 of the 103 studied, neurotic behaviour in 17, and psychosis or aggression in nine each; four patients were inadequate personalities and two persistently criminal.

Discussing the treatment of temporal lobe epilepsy, Dr. CHRISTOPHER OUNSTEAD (Oxford) emphasized the importance of prevention. Better management of birth injury or other trauma, encephalitis, meningitis, and status epilepticus might have prevented the development of temporal lobe epilepsy in 50% or more of one series of children with the condition. Some children appeared to have an inherited predisposition to status epilepticus in early childhood. Often precipitated by fever, these attacks differed from the more familiar febrile convulsions, damaged the temporal lobe, and caused subsequent temporal lobe epilepsy.

Another problem, mentioned by Dr. Ounstead in the subsequent discussion, was the management of hyperkinetic children, who made up 8.2% of all those with any sort of convulsive disorder in childhood. Of these 80% were boys; they usually slept well, but were hyperactive by day with euphoria and a brief attention span. They did badly at school, and their treatment required special care since phenobarbitone made them even more lively and amphetamine produced a retarded depression. As they grew up, hyperkinetic children usually became slow and stolid.

Childhood Epilepsy

Childhood epilepsy was subdivided into three age groups by Dr. BRIAN BOWER (Oxford). Attacks in the neonatal period seldom took the form of fits, and ranged from limb or face twitching to tonic episodes with cyanosis. They were most commonly due to birth injury, including anoxia (now a commoner cause than trauma) and hypoglycaemia; while hypocalcaemic convulsions occurred at the end of the first week of life, often after changing from breast milk to cow's milk. Infants with the hypoglycaemia of dysmaturity, on the other hand, showed the features of intrauterine starvation, being underweight and deficient in subcutaneous fat with papery, scaly skin. In about half there was a history of maternal pre-eclamptic toxæmia, and convulsions usually took place on the second day when the blood sugar fell below 20 mg./100 ml. Even vigorous treatment at this stage could not prevent a high incidence of permanent brain damage.

Fits were common between the ages of 1 month and 3 years, about 2.5% of children having one or more at this age. It had also recently been shown that pertussis antigen could cause brain damage. While most children with febrile convulsions did not have epilepsy later, those with fits following pertussis immunization fell into a much graver prognostic group, in which the aetiology was frequently unknown and 85% became moderately or grossly subnormal.

The administration of corticosteroids suppressed the fits and might be able to prevent brain damage if started within a day or two of the first spasm.

Concluding, Dr. Bower said that fits in children of 3 years and over took the form of grand or petit mal or temporal lobe epilepsy, the last being particularly difficult to diagnose and treat.

Behaviour Disorders

Mr. CHRISTOPHER BAGLEY (London) described a recent study of behaviour disorders—mainly aggression, anxiety, or

"mixed"—in 118 epileptic children referred for neurological investigation. Disturbance of a severity comparable to that seen in non-epileptic children referred to child guidance clinics was found in 43%. Brain damage and minor motor fits were significantly associated with aggression, while stressful environmental factors—poverty, overcrowding, and disturbed parental behaviour—were related to aggressive and mixed disorders. On the whole, a high intelligence quotient was associated with normal or anxious behaviour, and a low one with hyperactivity or aggression. The study had included an excess of children from the upper social classes, which suggested that those from lower classes who lived away from a teaching hospital did not receive adequate investigation of their epilepsy. This point was taken up later by Lord Cohen, who pointed out that the 1956 Committee under his chairmanship had for this very reason proposed the setting up of special diagnostic centres for epilepsy. Unfortunately, hardly any were yet in existence.

Legal problems associated with epilepsy were covered by Dr. NORTHAGE MATHER (Manchester), who spoke on epilepsy and

crime, and Dr. L. A. LIVERSEDGE (Manchester) on driving. The latter claimed that Britain was at the bottom of the international league for liberality to epileptics; the present yardstick—it was not a regulation—demanded that a patient should have been free from attacks for five years, and without medication for the last two of them, before he could receive a licence. This situation forced epileptic patients to concealment, and it had been estimated that over 80,000 were on the road. It would be safer for them to drive *on treatment* than to stop drugs in order to get a licence, and Dr. Liversedge proposed a three-year period without an attack and regular medication under supervision, as conditions for a driving licence.

Importance of Accurate Diagnosis

Referring to epilepsy as a symptom not a disease, Dr. P. M. JEAVONS (Birmingham) emphasized the importance of accurate diagnosis and outlined the drugs at present in use for each type of fit. The aim of treatment was to enable the patient to lead a normal life. Statistics on employment, accidents, heredity, and other factors showed

that the attitude of society, and even of doctors, towards epilepsy was not justified by the facts. Each patient had to be considered as an individual; it was important to avoid saying "No."

Lord Cohen summed up the proceedings and reminded participants that epilepsy was a symptom of an underlying lesion, which should always be sought; failure to find one was due to our ignorance. Every nerve cell, whether in the brain or elsewhere, had its own level of stability, and trigeminal neuralgia might be regarded as epilepsy of the Gasserian ganglion, for instance. Lord Cohen concluded by discussing the ethical problems posed by epilepsy. There was no code of ethics laid down by the General Medical Council governing medical practice in England. The doctor had duties to his professional brethren, to society, and to mankind in general, as well as to the individual patient. Information about patients was already divulged every day for the good of the community. The doctor should reveal that a patient suffered from epilepsy when it was necessary for the public safety to do so. And the public should be educated to eliminate prejudice about epilepsy.

Pharmacists and the Sainsbury Report

[FROM A SPECIAL CORRESPONDENT]

On 10 November the School of Pharmacy of the University of London organized a meeting to bring together different viewpoints on the Sainsbury Report on the relation of the drug industry to the National Health Service.

Welcoming the report, Dr. F. HARTLEY (Dean of the School of Pharmacy) mentioned everyone's feeling of relief that full-scale nationalization was not proposed. Although approving the proposals to ensure some measure of price supervision by the Ministry of Health, he wondered just how expensive these new measures would be. He pointed out that British drug firms were, with their exports, responsible for over £30m. to the good in our balance of payments. Hence it would be short-sighted to try to limit the legitimate profits made by British firms, especially those who introduced new drugs. On the other hand, the very large foreign drug firms in this country, principally American and Swiss, were responsible for a small deficit in our balance of payments.

Development of New Drugs

Continuing, Dr. Hartley emphasized that the industry depended for its prosperity on the development of new drugs, and that in future the worth-while research groups would probably be found in as few as five or six large firms. He felt that there should not be much support for the firms producing imitation, or "me too," drugs, nor for those producing polypharmaceuticals, often in the guise of new drugs. These firms tended to be the smaller firms, and with the encouragement of the true innovators in the industry he felt that it was inevitable that the smaller

firms would not prosper in the next few years.

Mr. J. A. BAKER (chief pharmacist, Westminster Hospital, London S.W.1) spoke of our dependence on the drug industry for safe and cheap medicines. The incentives of the industry should not be removed. He welcomed the proposed Medicines Commission as inevitable, and likely to receive strong support from hospital pharmacists. He felt strongly that the Commission should be truly impartial and independent. More especially the Commission should not be responsible to the Minister of Health.

Mr. Baker thought that some firms were able to make what he considered to be excessive profits because the present periods of patent protection were too long. While protection was very necessary, a shorter period of protection might, he thought, lead to a greater incentive to firms to produce new drugs. He himself was very happy to see the adoption of one name for a drug with the abolition of brand names. From the nursing staff's point of view the proliferation of names made it very easy for nurses to prescribe the wrong drug, and for this reason it was found necessary for the hospital pharmacist to check every prescription in the hospital to make sure that it was clear.

Brand Names

While he agreed that the abolition of brand names had much to recommend it from the point of view of the hospital pharmacist, Dr. CHARLES STEVENS (with a background of international law and his work as an industrial pharmacist with Imperial Chemical Industries) felt that the Medicines Commission should have a certain amount of indepen-

dence, though it would not work well if it was responsible to no one at all. The best practical solution, he thought, was responsibility to the Minister, who in turn was responsible to Parliament. In Britain Ministers always had to answer Parliamentary questions which brought their departments' work into the light of day.

So far as brand names were concerned, Dr. Stevens pointed out that while these might seem unnecessary in Britain they were essential for a drug firm's overseas sales. A product could be patented in Britain, but generally abroad it was the process that was patented and not the final product. Once a new drug was released it was not long before a clever chemist had found a new route to the final product.

Discussing brand names, Dr. HARTLEY brought up the question of drug formulation—that is, presentation of drugs so far as particle size was concerned. The latter could have a profound effect on the biological availability of a drug, and this was a field in which there was much useful work to be done.

Dr. G. R. FRYERS (Bayer Products Ltd.) emphasized that the Sainsbury Report concerned itself with the *innovating* pharmaceutical industry. Competitive research teams were the basis of the industry, and large firms in the international market were needed to find new drugs—and these firms in turn depended on the sale of drugs internationally. Firms would succeed only if they did so internationally; unless changes in the regulation of the British drug firms now contemplated made for the prosperity of British firms in the United Kingdom they would fail internationally.

Christmas Quiz

(Answers at p. 755)

- What is ?
(a) Pigeon fancier's disease. (b) Pigeon crammer's disease.
- Who are ?
(a) the Amish, (b) the Jumpers of Maine, (c) the clay-eaters of North Carolina, (a) the orange people ?

A

B

C

D

E

- Name the following whose anniversaries were remembered in 1967:

- The founder of a famous teaching hospital and of a specialist hospital in London.
 - A man whose father was a famous neurologist and who gave up medicine for polar exploration.
 - The originator of a staining method for histological and parasitic preparations.
 - The winner of two Nobel Prizes for physics and chemistry, whose contributions to medicine are still being exploited.
- And the following, the centenary of whose discoveries was celebrated:

- The originator of the antiseptic principle.
- The discoverer of amyl nitrite as a treatment for angina.

- See the illustrations:

(A) and (B) Both these buildings were opened in 1967. What are they, and where are they situated ?

(C) Whom does this relief commemorate, and where is it situated ?

(D) Whom does this statue commemorate, and what famous saying is associated with him ?

(E) What has happened to this document ?

- What are the following ?

(a) Straight back syndrome. (b) Stiff man syndrome. (c) Pickwickian syndrome. (d) Heart failure of the hunchback.

- What do the following children suffer from ?

(a) The happy puppet. (b) The bobble-head doll. (c) The Pekinese child. (d) Collodion babies. (e) Stinking infants.

- Who are patron saints of the following ?

(a) Spas. (b) Sufferers from toothache. (c) Nurses. (d) Sufferers from gout. (e) Doctors. (f) Epileptics. (g) Medicine.

- What are the dangers of:

Sniffing puff balls, gathering mushrooms, sawing maple logs, and collecting hay ?

- What do the following abbreviations stand for ?

(a) "Bilge." (b) R.D.S. (c) S.T.P. (d) E.C.F. or E.F.E. (e) D.D.D. (not an insecticide).

- In what literary works do the following characters appear ?

(a) Dr. Slop. (b) Dr. Gideon Gray and Dr. Adam Hartley. (c) "Doctor" Sganarelle. (d) Edwin Ingleby. (e) Dr. Andrew Manson.

- What diseases were:

(a) First described by the sufferer, (b) first described in the writer's son, (c) named after the original patients ?

Correspondence.

Letters to the Editor should not exceed 500 words.

Renal Glucose Threshold

SIR,—The paper by Professor W. J. H. Butterfield and his coworkers (2 December, p. 505) showing that the diagnosis of diabetes mellitus can be made in the absence of glycosuria is of especial importance in the field of geriatrics. I now have records of about 20 elderly patients presenting with neurological symptoms and signs where the diagnosis of diabetes mellitus has been previously dismissed because of the absence of glycosuria. Subsequent glucose tolerance tests have established the true aetiology, and appropriate treatment invariably results in satisfactory improvement.

One of my patients, a woman of 72 years, had increasing difficulty in rising from a sitting position and going up steps. She had been seen by a consultant physician and neurologist and, after extensive investigations, diagnosed as suffering from "thrombosis of the anterior spinal artery." The urine was sugar-free. The disability grew progressively worse and she became depressed. As a last resort her general practitioner referred her to the geriatric department, where weakness and wasting of the pelvic girdle muscles with depressed leg reflexes were found. A glucose tolerance test revealed a diabetic curve with aglycosuria, and treatment with tolbutamide resulted in full recovery.

A man of 78 being treated for osteoarthritis of the lumbar vertebrae developed progressive difficulty in walking, with signs of pyramidal tract disease, followed by severe bilateral wrist drop. There was no sugar in the urine, but the glucose tolerance curve was typical of diabetes mellitus. He quickly recovered with appropriate treatment. The radiological appearance of the lumbar vertebrae was consistent with Charcot's disease of the spine.

Another elderly patient was referred recently as suffering from "senile wrist-drop," and the diabetic origin of this was dismissed by her doctor because of the absence of sugar in the urine.

Professor Butterfield's recommendation that the idea of diabetes mellitus always being associated with glycosuria be abandoned is timely. The increasing numbers of elderly patients in our population and the easy acceptance of "senility" as the aetiological factor for many of their symptoms and signs, especially those involving the neurological and cardiovascular systems, should make us beware of overlooking the presence of diabetes mellitus even in the absence of sugar in the urine.—I am, etc.,

LEONARD ROSENTHAL.

St. James's Hospital,
Leeds 9.

SIR,—I have read with interest and appreciation the article on renal glucose threshold variations (2 December, p. 505) by Professor W. J. H. Butterfield and his team from Guy's. They have proved what I suggested in *The Diabetic Life* (15th edition) that the sugar threshold rises as age increases. My own

threshold (age 75, insulin for 45 years) has been proved by simultaneous blood-sugar and urine tests to have risen and is the first thing that has convinced me that, if not quite senile, I am getting on.

There is one point they do not mention which I wish they would investigate—the variability of the threshold. From my experience with many glucose tolerance tests the threshold is higher when the curve is rising than when it is coming down. I wonder if the rise after carbohydrate food or the fall after insulin affects the threshold in the same way? Of course, it's up to the investigators to practise and overcome the difficulties of getting small quantities of urine at the times required.

An old experiment years ago (unpublished) has a bearing on threshold discovery. A normal aglycosuric student volunteered to have a catheter passed into his bladder, and I filled it with 5% of glucose and let it out immediately. The next urine he could pass contained 0.3% of glucose by a titration method.—I am, etc.,

Transfusion Malaria

SIR,—Dr. Angela E. Vartan's description (25 November, p. 466) of a case of *Plasmodium malariae* infection following blood transfusion was of much interest, as the high incidence of such accidentally induced cases of quartan malaria has created some concern, especially in countries where malaria eradication has been achieved or is in its final stage. In addition to the data from Yugoslavia published by Lepeš¹ and quoted in Dr. Vartan's article there are more recent reports from Romania and from the U.S.S.R. which indicate the extent of the problem. Thus in Romania during the period 1959–65 there were no fewer than 112 cases of *P. malariae* infections subsequent to blood transfusion.² In 86% of these cases the donor's blood was conserved at 4°–6° C. for one to five days, but in three cases of induced malaria infection the blood had been kept for 12 days.

In the U.S.S.R. Sergiev and his colleagues³ reported that during the period 1963–5 out of 47 cases of *P. malariae* infections 33 were due to blood transfusion or to "haemotherapy." The latter procedure, quite common in Eastern Europe, consists of intramuscular injection of 10–20 ml. of blood taken from another person, usually the mother, for protection of children against measles. Six cases of *P. malariae* in children were due to such an occurrence.

The detection of the latent or asymptomatic infection with *P. malariae* is very difficult, though the fluorescent antibody test may be of value in this respect and should be more

widely used for the exclusion of some potentially infective blood donors.

Parasites of *P. malariae* can remain dormant for many years, and the presence in Britain of an immigrant population coming from countries where quartan malaria is not uncommon makes Dr. Vartan's paper particularly timely and important.—I am, etc.,

Viruses in Diarrhoeal Disease

SIR,—Despite a widespread impression to the contrary, there is little evidence to incriminate enteric viruses detectable by current diagnostic techniques as significant causes of diarrhoeal disease. In order to illustrate the unrewarding results of testing routine faecal specimens from patients with uncomplicated diarrhoea or gastroenteritis, we have analysed the results of testing 748 such specimens, mostly from children, during the past seven years.

Viruses were isolated from 93 (12%) in monkey kidney or human amnion tissue cultures, the percentage positive in different years ranging from 7% in 1966 to 18% in 1962. At least 25 different virus types were represented: 8 polioviruses, 11 Coxsackie viruses, 51 E.C.H.O. viruses, 13 unidentified enteroviruses, and 7 typed and 3 untyped adenoviruses. The largest groups of typed viruses were E.C.H.O. 14 (11 cases), E.C.H.O. 11 (9 cases), and E.C.H.O. 8 (8 cases). Most of the E.C.H.O. 14 isolations were made in 1962, when the same virus was also isolated from cases of neurological disease.¹ The E.C.H.O. 11 isolations were scattered over five different years, and no clearcut association of this or other types of enterovirus emerged from an analysis of all isolations of enteroviruses in 1960–4.² No viruses were isolated from various outbreaks affecting children or adults in nurseries, schools, colleges, and factories. Although an earlier study from this laboratory³ suggested a special association of E.C.H.O. virus 7 with diarrhoea, we have not found this again. In a comparison of closely matched children with respiratory or diarrhoeal disease in this hospital, similar viruses were isolated from the stools of both groups.⁴ Type 3 adenovirus was associated with gastrointestinal and respiratory symptoms in a small outbreak investigated in 1960,⁵ but we have encountered no similar episode in later years.

Chance coincidence of an outbreak of diarrhoea with a period of high prevalence of an enterovirus may explain some of the reported associations of enteroviruses with diarrhoea.^{6–8} No evidence of the importance of enteroviruses or adenoviruses

emerged from large studies in Texas⁶ and South Africa.¹⁰⁻¹² Altogether it seems unlikely that enteroviruses or adenoviruses are significant causes of uncomplicated diarrhoeal disease. Routine virological investigation by present techniques of stools from diarrhoeal patients is an unrewarding diversion of effort. Perhaps when the technical trick of demonstrating hepatitis virus has been discovered a new group of agents may be found responsible for that large majority of diarrhoeal illnesses in which neither virological nor bacteriological tests are currently successful.—We are, etc.,

Withdrawal of Heroin

SIR,—The biochemical mechanisms of physical dependence on drugs remain obscure. We wish to record a phenomenon in which marked manifestations of withdrawal followed a change from intravenous to intramuscular administration of a fixed dose of heroin in a long-standing addict, with recovery on returning to the intravenous route.

A 52-year-old woman was admitted to St. Stephen's Hospital, Chelsea, on 11 December 1966 with bronchial asthma. She had become addicted to morphine given for postoperative pain following accidental ligation of the right ureter at ovariectomy in 1936. She changed to heroin several years later, and at the time of admission was receiving 2 gr. (120 mg.) of heroin with 12.5 mg. cocaine intravenously five times daily.

She was treated with tetracycline, bronchodilators, and later A.C.T.H., with marked improvement in her bronchospasm.

Her general condition, nevertheless, did not improve, and though her chest was no longer troublesome she became confused, restless, and agitated. She became increasingly disorientated and developed a coarse tremor of the upper and lower limbs. During her asthmatic attack she had been experiencing difficulty in "fixing" herself, and had been receiving her heroin and cocaine intramuscularly. It was felt, therefore, that though she was in fact having her normal dosage she was suffering from withdrawal symptoms due to a change in the method of administration. At this time her condition was critical, and though heart action, lungs, and blood

pressure appeared to be normal she was moribund. A Gordh's needle was therefore inserted and intravenous administration of heroin and cocaine begun at the same dosage. She improved rapidly and was soon able to resume her own intravenous injections.

The practical problems of opiate addiction appear to be related mainly to the psyche of the addict; withdrawal, if desired, is usually easy in the early stages at least, but relapse is very frequent. Experience in prison suggests that withdrawal symptoms may be of psychic origin. Nellans and Masee¹ reported from the Atlanta State Penitentiary in 1929 that complete withdrawal could be accomplished with only minor symptoms, and suggested that the most powerful therapeutic agent was the absolute certainty that no further drug would be given. On the other hand, withdrawal can be reproduced in animals, and, though differences in route of administration do not influence effectiveness, monkeys given morphine for two months become moribund following withdrawal, and recover when the drug is given.²

It is striking that death from withdrawal does not seem to be a hazard for the present-day addict, though he is at risk for many other reasons. Helpers and Rho³ reported 1,561 deaths in addicts, none related to withdrawal. It is said that "exhaustion" may occur; treatment, with insulin for instance, may contribute.⁴ We felt that our patient would have died from withdrawal symptoms if she had not been returned to intravenous from intramuscular therapy. This, however, remains speculative.

This case emphasizes the physical aspect of withdrawal. If drugs of dependence become essential to some metabolic process, it may be that a certain concentration is required which would explain the effectiveness of intravenous heroin. This may have therapeutic implications, though such a severe reaction to withdrawal appears to be very rare.—We are, etc.,

Carcinogenic Properties of Ortho-dianisidine

SIR,—In his letter (21 October, p. 172) Dr. D. G. Illingworth states that Occultest and Hematest reagent tablets (Ames) contain ortho-tolidine, but doubts whether, if used according to the manufacturer's instructions, any risk is incurred in their use. The manufacturer's leaflets which accompany the tablets confirm that both preparations contain ortho-tolidine. In view of the fact that they state "hands, droppers, and working area must be clean and free from any traces of blood," it is clear that a technique which involves the tablets coming in contact with the skin is envisaged.

Ortho-tolidine (dimethylbenzidine) is listed in the *Prescribed Industrial Diseases Regulations No. 39*¹ as a carcinogen in man, and is

also listed in the *Carcinogenic Substances Regulations*, which become law on 9 December.² It is known that the aromatic amines as a class can be absorbed through the skin.³ These tablets may be handled occasionally (for example, by doctors) or up to several times each working day (for example, by certain nurses or laboratory technicians).

According to the *British Medical Journal* (22 July, p. 189), "although it is not possible to say that there is a level of exposure to the carcinogenic aromatic amines below which there is no risk, the hazard to trained laboratory workers must be small." It may be that all that is necessary to obviate the risk is that a no-touch technique be employed. If so, clear instructions to this effect are necessary on the leaflet. Those interested are referred to *Precautions for Laboratory Workers who Handle Carcinogenic Aromatic Amines* published by the Chester Beatty Research Institute. However, the moral argument seems irrefutable that the persons concerned should have an opportunity of knowing that the tablets may contain a carcinogen (for example, by means of a label on the container), so that they may choose whether or not to use them.

The analogy which Dr. Illingworth makes with cigarette-smoking is a poor one. There may or may not be merits in having their carcinogenic action marked on the packet as he suggests. But employees are rarely instructed by employers to smoke as part of their duties, and in any case this hazard is already public knowledge.—I am, etc.,

DONALD ACHESON.

Streptomycin, I.N.H., and Thiacetazone

SIR,—We have read with interest the letter by Dr. S. N. Dutta and colleagues (7 October, p. 55) on streptomycin, I.N.H., and thiacetazone. We are concerned lest this should deter others from using thiacetazone in the treatment of tuberculosis in developing countries. The cheapness of the drug has made it possible for people to have effective treatment, whereas before the expense of streptomycin and P.A.S. often led to inadequate courses of treatment. We are convinced of the value of thiacetazone and isonicotinic acid hydrazide (I.N.H.) alone in the majority of cases.

In 1965-6 we conducted a trial on 90 patients in order to investigate the development of drug resistance in the treatment of pulmonary tuberculosis with thiacetazone and I.N.H. During this trial there were six patients who had a rash, one having exfoliative dermatitis. One patient had jaundice, thought to be due to the drugs.¹ The rash was mostly of the maculopapular type; it left behind a black pigmented area which persisted for many months. The case of exfoliative dermatitis was of a very severe type. The rash appeared usually about the end of the third week. It did not regress quickly with the cessation of the drug. There was some relief of severe skin irritation when treated with antihistamine drugs and corticosteroids. It is now thought advisable to stop the drug immediately

on the appearance of any type of rash. Most of the patients who developed the rash were later treated with streptomycin and I.N.H., and still later with I.N.H. and P.A.S. without recurrence of the rash.

Provided a watch is kept for these complications, there is no reason why I.N.H. and thiacetazone should not form the basis of treatment for most cases, but we would recommend a smaller dose than that used by Dr. Dutta and his colleagues (that is, thiacetazone 225 mg. and I.N.H. 450 mg./day). The commonly accepted dose for an adult is thiacetazone 150 mg. and I.N.H. 300 mg./day. This has been found to produce a satisfactory clinical response; and this dose of thiacetazone is as effective as P.A.S. 10 g./day in preventing the emergence of resistance to I.N.H.²⁻⁵ The dosage of 150 mg. thiacetazone and 300 mg. I.N.H. for an adult is thought to be critical, and lower doses seem less effective.⁶ A higher dosage of thiacetazone (200 mg.) was found to be toxic in the early 1957 East African/B.M.R.C. trial,³ and also by Bunn.⁷ Leprosy workers also have recommended not exceeding the 150-mg. daily dose.⁸⁻¹¹

If it is possible to determine drug resistance it is better to avoid the combination of thiacetazone and I.N.H. if primary I.N.H. resistance is present or develops early in the course of treatment. Thiacetazone resistance is less important and often only temporary.—We are, etc.,

Sarcoid Myopathy

SIR,—The bald statement in the medical memorandum by Dr. P. S. Talbot that "The skin lesions of sarcoidosis were first described by Boeck (1899) . . ." (25 November, p. 465) is incorrect. It is surprising that the Editor of the *British Medical Journal*—of all editors—does not challenge such a remark, for the skin lesions of sarcoidosis were first described by a predecessor of his in that office.^{1,2}

Even more pitiful is the fact that a miliary granuloma, extracted by blind biopsy of an anonymous muscle, should be magnified, with no other evidence, into the multisystem disease sarcoidosis. This is reckless devaluation of a noble disorder.—I am, etc.,

Pseudomonas Infection in Hospital

SIR,—In their description of sterilizing the Engström ventilator your correspondents from the Karolinska Hospital (2 December, p. 548) said that they use ultrasonically nebulized 70% ethyl alcohol. We should like to draw your attention to a hazard in this technique, because the method, while bacteriologically effective in killing all bacteria except spores, will give a remarkable explosion if the alcohol mist is sparked in an oxygen-enriched atmosphere. This alcohol mist is also inflammable in air. None of the ultrasonic nebulizers we have examined can be considered flame-proof, and therefore this method of sterilizing ventilators cannot be recommended.

For these reasons we are currently investigating methods of sterilizing such ventilators using ultrasonically nebulized, non-toxic, liquid halogenated hydrocarbons, and hope to publish our results shortly.—We are, etc.,

Achilles Tendon Reflex Time

SIR,—Dr. M. Zachmann (2 December, p. 528) suggests that the shortening of the Achilles reflex time that occurs during insulin hypoglycaemia may be due to adrenaline release. We have confirmed Fejér and Kun's observation¹ that adrenaline does reduce Achilles reflex time. The intravenous infusion of adrenaline (10 µg./min.) reduces the time to half-relaxation of the human calf twitch by some 15%, whether elicited by an ankle tap or by stimulation of the medial popliteal nerve. This effect is abolished by prior β-adrenergic blockade; which also significantly prolongs the duration of the Achilles reflex in thyrotoxicosis. The results of these studies are to be published elsewhere.^{2,3}—We are, etc.,

Resuscitation Appliance

SIR,—When using the Brook airway or the Ambu bag for resuscitation certain problems arise. With the Brook airway considerable energy is required to blow down it for any length of time, and the problem is magnified if external cardiac massage is being performed at the same time. The Ambu bag is commonly used in conjunction with a face-mask, and it can be difficult to place the mask over the patient's face with an airtight seal and at the same time ensure elevation of the chin and backward tilt of the head.

We have devised an apparatus to overcome these problems. It consists of an adaptor to allow the use of an Ambu bag attached to the mouthpiece of a Brook airway, keeping

the advantages of both instruments and avoiding some of the disadvantages. At present we are using a brass adaptor which is both airtight and easily removable. It is hoped to produce a plastic one incorporating a small side-arm extension to allow catheter suction through the airway, without the need for temporary disconnection of the apparatus.

With this apparatus it is easy to produce an airtight fit round the patient's mouth. The tongue can be kept well out of the way. There is less risk of airway obstruction therefore, and should it occur it may be easily recognized by feeling the resistance in the compression of the bag. The device is simple to operate, and the bag can be disconnected easily from the airway to allow catheter suction through the airway.

It is safe for paediatric use. Over-inflation of the infant's lungs is a well-recognized risk of expired air resuscitation. Using an Ambu bag with a smaller Brook airway, the maximum pressure reached when the bag is squeezed with one hand is 35 cm. of water. This is generally recognized as being safe for infants.

Oxygen may be administered by the Ambu bag, allowing an enrichment of air with up to 50% oxygen, compared with ordinary expired air respiration which contains 14% to 18% oxygen. The small risk of infection with expired air resuscitation is eliminated.—We are, etc.,

Body Building on Drugs

SIR,—My attention has recently been drawn to your leading article on this subject (11 November, p. 310) and also to the letter from Dr. D. E. Pearsons (same issue, p. 353) and the letter of Dr. J. R. Owen (25 November, p. 484). This is becoming a very real problem among those closely associated with strength athletes of all kinds.

Unfortunately, my experience in weight-lifting and body-building circles suggests that these drugs do in fact tend to augment muscle bulk in men who are concomitantly engaged in a strength or body-building

regimen of heavy exercise and at the same time are on a high food intake with protein supplements. I write "unfortunately" because the success of these athletes in increasing their muscle size by these means is being copied by more and more young men in the hope of finding an easy pathway to massive muscle size and strength. The tendency often is to rely more on the drugs than increased exercise.

The amateur organizations with which I am associated have heard of many cases of young weight-lifters and body builders being prescribed anabolic steroids more or less on request from their general practitioners. There certainly does seem to exist a "black market" of these drugs, particularly in the U.S.A., according to athletes I have spoken to when I have been serving as international judge at contests of amateur athletic physique. We are very concerned indeed about this trend, and many articles have been written in the official journals of the organizations to which I am medical adviser deploring the use of drugs and pointing out their dangers. As far as the strength and physique contests held by these organizations are concerned, we now make it a rule that no athlete on these drugs is allowed to enter. However, it is very difficult, if not impossible, to determine which athletes are using drugs, and so our ban is rather an empty threat and not much of a deterrent.

I would like to use the medium of your columns to urge that all doctors approached to prescribe anabolic steroids for this purpose refuse to do so. Wide publicity of the very positive dangers of using these drugs, particularly when taken by mouth, would also be welcomed.—I am, etc.,

I. J. MACQUEEN,

Medical Adviser to the Society of
Amateur Weight Lifters and the
National Amateur Body-Builders'
Association.

Croydon, Surrey.

Why Sternal Marrow?

SIR,—Dr. M. W. P. Carney (2 December, p. 512) in his interesting article on serum folate values in psychiatric patients mentions the uncomfortable and frightening procedure of sternal marrow puncture.

I wonder why the iliac crest is not more widely regarded as the site of choice for this procedure. It is certainly less disturbing for the patient and can be performed with safety even in the absence of complete co-operation and in the presence of severe osteoporosis.

It is particularly simple to perform where musculature is lax and subcutaneous tissue scanty, as in the case of the majority of geriatric patients.—I am, etc.,

Perth Royal Infirmary,
Perth.

MARY SHAW.

Investigating Hypertension

SIR,—Having written to you (26 August, p. 557) about a paper on the investigation of hypertension (29 July, p. 306), I was pleased to see your sensible leading article on that subject (9 December, p. 569) based on the reported experience of the Royal Postgraduate Medical School.

Our experience has been similar, and from the beginning we have had no enthusiasm for the more complex forms of investigation

except in those patients in whom some relevant abnormality was likely to be found and which might lead to special treatment. The disappointing results of surgical treatment in most patients are well known. We have also been impressed with the efficacy of antihypertensive drugs properly given to patients with renal hypertension who are not suitable for surgery. Adequate control of the blood pressure can usually be obtained by paying sufficient attention to detail in the individual patient, and often by giving appropriate combinations of antihypertensive drugs.

I agree that all that is required in the majority of patients are serial recordings of the blood pressure, examination of the retinae with fully dilated pupils, a 12-lead electrocardiogram; examination of the urine for protein, abnormal constituents on microscopy, and culture; a specimen of blood for estimation of the blood urea, the erythrocyte sedimentation rate, electrolytes; and a good intravenous pyelogram. In the well-recognized small group of patients in whom renal arteriography is indicated the need for this can be assessed by an isotope renogram, for which the patient can always if necessary be referred to a special centre.

Most of the above tests can, of course, be carried out on an outpatient basis, but if it seems probable that some underlying disease is present or that treatment is indicated the patient should be admitted to hospital for the necessary investigations and the assessment of renal function. If treatment is indicated the institution of an appropriate regimen with antihypertensive drugs can be established, and then be continued by the general practitioner with occasional reassessment at hospital by an interested and experienced physician.—I am, etc.,

Primigravida or Primipara?

SIR,—I feel it is at times at least misleading when the words "primigravida" and "primipara" are used as though they were synonymous. Surely a primigravida only becomes a primipara when she gives birth, and prior to labour is nulliparous.—I am, etc.,

Port Talbot,
Glam.

R. S. SAXTON.

Obstetric Forceps or Vacuum Extractor?

SIR,—I had hoped to avoid taking any further part in this correspondence, but I feel that I cannot let the letter of Mr. A. F. Clift (2 December, p. 553) go unanswered.

I use the vacuum extractor to deliver the child in cases of either maternal or foetal distress when this arises before full dilatation of the cervix, provided the cervix is half or more dilated. I do not "drag the baby through an undilated cervix" and I do not admit that the procedure carries with it "the serious risks of brain damage, uterine rupture, and ruined uterine supports with subsequent prolapse." If I thought these risks were present I should certainly abandon the use of the instrument in the first stage. I believe that the *modus operandi* of the vacuum

extractor applied before full dilatation of the cervix is to stimulate better co-ordinated uterine contractions by bringing the presenting part into improved contact with the cervix and so to promote rapid dilatation of the cervix in an almost physiological manner. The results obtained in our series of over 1,000 deliveries in Worcester, as well as those from many other centres, show that this can be achieved with a minimum of risk to the child, and in a follow-up study of mothers delivered during the first stage of labour the incidence of cervical trauma and of relaxation of the uterine supports was no greater than in a similar series of spontaneous deliveries. Furthermore, we have seen no case of cervical incompetence in any of our cases delivered by vacuum extraction in the first stage. These results have been obtained not only by "a busy registrar or an active consultant" (Mr. D. B. Brown (25 November, p. 487)) but by some 45 different operators, including house-surgeons and postgraduate students with little or no experience of operative obstetrics. J. Chassar Moir in *Kerr's Operative Obstetrics* suggests that much of the opposition to the vacuum extractor comes from those who have no experience of its use, and I am confident that this opposition would be much less if senior obstetricians would put it to the test.

The most recent major study of this question comes from Helsinki, where Sjostedt,² in a series of approximately 800 forceps deliveries compared with the same number of vacuum extractions, found the perinatal mortality three times as great in the former group. It is not surprising, therefore, that the vacuum extractor has very largely displaced the forceps throughout the Scandinavian countries and Germany, as well as in many parts of the British Isles.—I am, etc.,

J. A. CHALMERS.

β -Adrenergic Blockade and Cardiac Arrhythmias

SIR,—Dr. G. Sloman and Dr. Mary Stannard's paper (2 December, p. 508) lists among the treated arrhythmias only two examples of atrial flutter. Previous reports on the use of pronethalol¹ and propranolol¹ have suggested that atrial flutter is less responsive to β -adrenergic blockade than are other supraventricular arrhythmias. Sloman and Stannard's Case 13, further, cannot be held to be typical of atrial flutter in general, since the underlying disease was thyrotoxicosis. Since thyroxine is known to sensitize the heart to sympathetic stimulation, it would be expected that atrial flutter due to thyrotoxicosis might be more responsive to sympathetic blockade than would flutter due to other causes. Of particular interest, therefore, is the other case (Case 17) of atrial flutter, whose response is described thus: "... the ventricular rate slowed initially, and later there was reversion to sinus rhythm."

I have recently had occasion to treat three patients admitted to hospital with "tachycardia" which subsequently proved to be due to atrial

flutter with 2 to 1 block. Full digitalization regimens failed to control the ventricular rate. In each case, and subsequently propranolol was given intravenously in a dose of 3 mg. over a period of 10 minutes with continuous electrocardiographic monitoring. In all three patients the immediate effect was to increase sensitivity to vagal stimulation by carotid sinus massage, which produced a much greater degree of ventricular slowing than before propranolol; slowing which persisted for some seconds after cessation of massage. Oral propranolol was then given in a dose of 10 mg. every four hours. By the next day the degree of atrioventricular block in all had become 3 to 1 or even 4 to 1, without any alteration in the flutter rate. However, at some stage between 48 and 72 hours after beginning propranolol sinus rhythm was found to have returned, and no further flutter episodes occurred. In two patients the underlying cause was chronic myocardial ischaemia, and the third had rheumatic mitral valve disease with recurrence of acute rheumatism.

At first it seemed that the restoration of sinus rhythm in a possibly paroxysmal atrial flutter might be spontaneous and unrelated to therapy. However, the similar pattern in these three cases, and in Drs. Sloman and Stannard's case, suggests that propranolol does in fact have a dual mode of action in atrial flutter, the first being the depression of ventricular excitability or of atrioventricular conduction, so that there is an increase in the degree of A-V block, without any fall in atrial rate. At a later stage, presumably following a cumulative increase in drug effect, the abnormal atrial discharge is suppressed, and sinus rhythm is restored.

It is apparent that propranolol may well be a worth-while addition to the list of drugs for the treatment of atrial flutter.—I am, etc.,

Postgastrectomy Problems

SIR,—In his most helpful article on post-gastrectomy problems (18 November, p. 403) Mr. J. A. Williams states that "the treatment of gall-bladder disease presents few problems" when it is found to be the "cause" of recurrent dyspepsia after gastrectomy. It is a common experience that in patients with gall-bladder disease alone cholecystectomy fails to relieve dyspepsia in a large proportion of cases, and the treatment of this symptom is anything but free of problems. I wonder if Mr. Williams has had a different experience with postgastrectomy patients. If so, may this not be a significant observation?—I am, etc.,

ALAN G. JOHNSON.

London W.6.

Coxsackie B5 Virus

SIR,—It was stated in the leading article "Outbreaks of Coxsackie B Infection" (9 December, p. 570) that no Coxsackie B5 virus infections were reported from Northern Ireland during 1965. In fact, eight Coxsackie B5 infections occurring during 1965 were reported to the Central Public Health

Laboratory at Colindale and were published in the weekly summaries of the Public Health Laboratory Service. The details of these patients were as follows:

Patient	Age	Sex	Illness	Month of Illness
1	5	M	Healthy excreter	August
2	34	F	Aseptic meningitis	September
3	4	F	Aseptic meningitis	October
4	3	M	Aseptic meningitis	November
5	29	F	Aseptic meningitis	November
6	39	F	Pericarditis	November
7	60	F	Bornholm disease	November
8	25	M	Aseptic meningitis	December

Coxsackie B5 virus was isolated from faeces of the first seven patients, while in Patient 5 virus was also isolated from the cerebrospinal fluid. Patient 8 was diagnosed by finding a rising titre of Coxsackie B5 virus antibody.—I am, etc.,

Congenital Dislocation of the Hip

SIR,—I read Dr. C. O. Carter's letter (9 December, p. 618) with considerable interest. With an incidence of abnormally lax hips as high as 1 in 40 at birth in certain parts of Britain, it obviously must happen fairly frequently that two or more children with congenital dislocation of the hip are born into one family, either in the same generation or spanning the generations. The suggestion that such children merit specially careful examination is not right. There are no first- and second-class citizens in congenital dislocation of the hip. Every baby at birth is entitled to the most careful examination available to it.—I am, etc.,

Hope Hospital,
Salford 6.

T. G. BARLOW.

Which Stethoscope?

SIR,—Dr. B. J. Peck (9 December, p. 620) describes a transistorized stethoscope which would no doubt cost very little to make from parts of an old hearing-aid. But surely anyone but the most penurious practitioner would be better advised to invest in a cheap electronic stethoscope such as I myself have been using almost exclusively for the last two years.

My own hearing has deteriorated only marginally, but nobody could hope to hear as well with an ordinary stethoscope as one can with the neat little instrument I carry round in my pocket. Its general shape and size are similar to the old-fashioned instrument, but with it one can hear heart sounds beautifully even through layers of an old lady's clothing that it would take much time and grumbling to remove. A foetal heart can be heard in circumstances where no old instrument could pick it up. Amplification is variable and there is a choice of high and low tone chest-pieces, though I find the latter generally useful. To me it is quite amazing that neither

Dr. Peck nor the article to which he refers makes any mention of the modern transistorized stethoscope. On the other hand, it is fair to say that in this day and age of hearing-aids and all sorts of sound-reproducing appliances in patients' homes I have yet to meet a colleague who has anything better than two old "speaking tubes" joined to a little funnel to enable him pick up various sounds from the human body.—I am, etc.,

Eye, Suffolk.

SHACKLETON BAILEY.

"Mediflash"

SIR,—Those of us who deal with emergencies, especially road accidents, should be grateful to Dr. R. Snook (2 December, p. 556) for having made it possible for us to carry a warning/protective device on our cars.

Our own chief constable welcomed its introduction and would favour an even brighter light which could be seen more clearly in daylight, fog, or storm. If we are circumspect in the use of this lamp it will be respected by police and public alike. I and my colleagues have already proved its efficacy during the recent spate of accidents from ice and fog. May I add two comments on Dr. Snook's excellent letter?

In Britain emergencies are an everyday occurrence, a thousandfold so. Emergency work is dangerous and those undertaking it deserve co-operation. Dr. Snook and the B.M.A. officials must not be thwarted in their endeavours to further the humanitarian services of our profession, nor be discouraged by the apparent lack of comprehension of others.—I am, etc.,

KENNETH C. EASTON.

Catterick Village,
Richmond, Yorks.

Megaloblastic Anaemia and Ascorbic Acid

SIR,—We have read with interest the claim by Dr. P. Asquith and his colleagues (18 November, p. 402) that the megaloblastic anaemia in a scorbutic patient responded to ascorbic acid alone. The diet of this patient before admission was obviously low in folate as well as ascorbic acid. He had a low serum folate activity associated with megaloblastic erythropoiesis, and it is difficult to avoid the conclusion that his anaemia was, in part at least, the result of folate deficiency. The authors state that he returned to haematological normality when given ascorbic acid 500 mg. daily and "a folate-deficient diet composed of tea, bread, jam, eggs, fish, chicken, minced meat, and potato." The last five items in this diet contain significant amounts of folate; without details of a cooking process designed to reduce the folate content and assays of the food as eaten, this diet cannot be described accurately as folate-deficient.

We have assayed various foods using *Lactobacillus casei* as the test organism, and have found eggs to contain up to 50 µg. per yolk and potatoes 6.8 µg. per 100 g. The *Agricultural Handbook* of the U.S.A. gives the following folate concentrations¹:

Bread (white)	...	13.8 µg./100 g.
Fish (raw)	...	164 " "
Chicken	...	3.1 " "
Minced meat	...	4.3 " "

The observation that the fasting serum folate activity remained low does not disprove that the haematological response was the result of folate in the diet after admission, as it is possible to treat megaloblastic anaemia without replenishing body folate stores.³

Any relationship between folate metabolism and ascorbic acid remains obscure, but it has been shown that patients with only slight evidence of folate deficiency may become frankly megaloblastic when treated with ascorbic acid alone and a folic acid-free diet.^{4,5} The contradictory reports of ascorbic acid converting megaloblastic erythropoiesis to normoblastic and normoblastic erythropoiesis to megaloblastic are probably explained by the former studies not being conducted on folate-free diets, and by an increased utilization and low intake of folate in the latter.

As a patient who has scurvy is likely to be folate-deficient, it seems sensible to give folic acid to all scorbutic patients and also to ensure that they are not deficient of vitamin B₁₂ and iron.—We are, etc.,

Hypercalcaemia and Malignant Tumours

SIR,—The spirited reply (11 November, p. 355) to my earlier letter (23 September, p. 799) does not increase the likelihood that the bronchial carcinoma described by Dr. W. E. Medd and his colleagues (2 September, p. 590) was producing a parathyrotropic substance. In stating that hyperplastic parathyroid glands have not been found in patients with hypercalcaemia and non-parathyroid malignant tumours I was quoting from the authoritative paper by Sherwood and his coworkers.¹ Roth² in 1964 reviewed the literature and considered that the case was not proved for the existence of a parathyrotropic substance in any of the papers where this had been suggested as the indirect cause for the hypercalcaemia. He thought that primary chief-cell hyperplasia of the parathyroids³ was the cause for the hypercalcaemia in each of the patients (who had an incidental tumour in another organ).

The two papers that Dr. Medd quotes in support of a mechanism mediated via the parathyroids causing the hypercalcaemia are extremely wispy struts when examined more carefully. In the first,⁴ the patient had primary chief-cell hyperplasia of the parathyroids. Dr. Castleman examined the glands and suggested that there was no need to implicate bronchogenic carcinoma at all in the pathogenesis of the hypercalcaemia, and that it could be considered as a coexisting independent pathologic process. In the

second,⁵ a case-record, two small parathyroids only were found at necropsy, and the evidence for mild hyperplasia was based on the absence of fat in the glands, and this was in a patient cachectic from loss of body fat. The glands, on description, were unlikely to have been of sufficient size to have produced a plasma calcium level in excess of 17 mg./100 ml. More undermining of Dr. Medd's support, however, is the fact that Dr. A. H. Tashjian, jun., made an immunoassay of the primary tumour and found parathormone-like activity in it. These two papers are hardly good evidence when placed alongside the many published reports where no parathyroid hyperplasia was discovered to explain the hypercalcaemia.

If Dr. Medd will get in touch with me I shall be happy to try to arrange that the tumour from his patient be assayed for any parathormone-like activity.—I am, etc.,

Medical Science: Master or Servant?

SIR,—In his reply to Lord Platt's Harveian Oration (25 November, p. 439) Professor W. S. Peart (9 December, p. 616) calls for the provision in university medical departments of more and more sophisticated workers to carry out ever smaller and more refined measurements. With diffidence I suggest that he thus seems to confirm the validity of Lord Platt's contention while attempting to refute it.

For years many of us, remembering the time when doctors were still able to talk to their patients, have been waiting for just such a lead as Lord Platt has now given. We feel that only by restoring a proper balance between the art and science of medicine shall we find true satisfaction for ourselves and our patients.—I am, etc.,

Ringwood,
Hants.

R. VAUGHAN FACEY.

Institutional Care of the Mentally Subnormal

SIR,—Dr. G. B. Simon (2 December, p. 549) takes us (2 September, p. 573) to task (a) for not considering children on waiting-lists and (b) for underestimating the proportion of children requiring "medical investigation or treatment of a kind necessitating hospital admission." Assessment of the needs of children on waiting-lists was not essential to the aims of our inquiry, which Dr. Simon ignores; nevertheless account was taken of them in estimating the number of children needing hospital care (Fig. 2 in our paper). The estimate of patients' requirements was made, not by us, but by the staffs of the hospitals, including Lea Castle. On the same point Dr. Simon seems to confuse the number

of patients (7) said to need hospital care for medical investigation and treatment with the total number (1,007) considered to need hospital care for any reason, mainly for mental and basic nursing.

Nevertheless we agree that Pilkington's estimate¹ (10%) of the proportion of patients who require "detailed specialist day-to-day diagnosis care and treatment" is a more acceptable indication of future needs, and like Dr. Simon we should be sorry to see the lower Birmingham figure misused.—We are, etc.,

Patient or Ailment?

SIR,—One gets the impression (*Supplement*, 9 December, p. 71) that the Private Practice Committee have failed to condemn a very curious attitude to general practice. From your report it seems that a general practitioner undertook the care of a patient for a "particular ailment," and that he and the patient conspired to keep this secret from her "N.H.S. doctor"—in other words from her regular general practitioner. May one ask whether a general practitioner can undertake the care of a particular ailment, not of the whole patient? It was evidently not a trivial matter, since she was admitted to hospital, apparently as an emergency. Given the chance, this sort of patient may end up by seeing Dr. Smith for her rapid heart, Dr. Jones for her goitre, and Dr. Brown for her exophthalmos!

And what of the ethical position? Should not the private general practitioner have insisted that if this patient had such little trust in her regular doctor as to deceive him deliberately, she should take steps to remove her name from his list altogether? She could then have truthfully told the hospital that she had no N.H.S. doctor. I would like to make it clear that I am by no means opposed to true private general practice. But for patients to remain on the list of one general practitioner (N.H.S.) and then to have secret consultations with a second general practitioner privately seems to me such an obvious cause of friction and confusion as to be worthy of strong discouragement.—I am, etc.,

Maidstone, Kent.

JOHN B. GLASS.

Hospital Management

SIR,—Once again professions of economy and efficiency (25 November, p. 482) are on the lips of public men. May I make three practical suggestions which would be simple to implement.

Hospital management committees still consist predominantly of laymen innocent of any real knowledge of the highly technical problems of a modern hospital. Admittedly things have improved, but the elderly seeking escape from boredom are still conspicuously

with us. Conversely the senior officers of the hospital on whom efficiency depends are hardly ever consulted. In theory there are advisory committees at which senior staff and hospital management committee members consult. In one case records show that over two years the attendance of the lay members of the hospital management committee was under 25%. At times the hospital staff found themselves without any hospital management committee representative with whom to consult. Is it not time hospitals were run by professionals with sufficient lay representation to prevent abuse? Few of us would care to invest our money in companies run by amateurs.

The medical superintendent is still with us, although in emasculated form. This system of imposing a doctor on others, usually without consulting them, is surely undemocratic and obsolete. Under it only chance decides whether this man can command the loyalty and respect of his colleagues. In the not infrequent cases where he cannot disharmony and frustration result. The elected officers of the senior medical staff committee should replace him.

Staff in efficient hospitals receive the same salaries as those in inefficient hospitals. Some financial incentive needs to be devised, and in this the advice of business consultants and efficiency experts should be taken.—I am, etc.,

Littlemore Hospital,
Littlemore, Oxford.

J. E. DUFFIELD.

Forging Prescriptions

SIR,—We would like to bring to your attention the fact that recently on two separate occasions patients have produced photo copies of their prescriptions given on previous occasions by the doctor. This is obviously helpful to the patients who require only a repeat prescription of their drug, and they could thus tell any strange doctor exactly what medicines they are on. However, the obvious problem arises that this photo copy has an exact signature of the doctor, and recently one of us (G. B. S.) had a quantity of prescription-pads stolen after breaking into his car. Of course the prescriptions were made use of and appeared at chemists with signatures vastly different from the signature of the doctor concerned, but as soon as the doctor's signature can be so easily found and forged then it may be difficult for the chemist to tell that the doctor has not himself prescribed the forged prescription.

Needless to say nearly all of the prescriptions returned by chemists were for drugs of the purple-heart variety. Perhaps it is necessary, as well as having a dangerous drugs register, to have an addicted drugs register.—We are, etc.,

B. D. LASCELLES.
G. B. STURROCK.

London E.1.

Mileage Allowances

SIR,—I am sure we are all grateful to the Negotiating Subcommittee of the Central Committee for Hospital Medical Services for obtaining an increase in the mileage allowances. I am indebted to Dr. N. L. Rowe (11 November, p. 361) for his lucid explana-

tion of the change of basis for calculating the new allowances which came into effect on 1 July 1967. No one can quarrel with the change from horsepower to cubic capacity in determining the class in which a car is to be assessed. I note that the circular announcing the change was issued by the Ministry of Health in July, although I suspect the Scottish Home and Health Department issued the circular later than July. The intimation of the increase in the allowances was published in the *Supplement* on 19 August (p. 121). It would therefore appear that the application of the "no detriment" clause was made retrospective to a date before the announcement, and, if so, I think this was unjustifiable and unfair.

My point is that it was a breach of contract to make the date on which the change became effective earlier than the announcement of the change. Did the Negotiating Subcommittee agree to this, and, if so, why, or did the Health Departments make this decree on their own?—I am, etc.,

Penicuik,
Midlothian.

JOHN G. MCWHIRTER.

Sickness Benefits

SIR,—There must be many general practitioners who believe, as I did, that the new regulations regarding sickness benefits meant that we should be refunded locum fees during sickness up to a maximum of £32 per week.

This is not so. I was recently unfit to work for eight days, and locums were employed for six surgeries at a cost of £18 18s. After completing a number of forms I was told that £7 6s. 3d. would be allowed. This was calculated on the following formula:

$$\frac{12}{60} \times \frac{8}{7} \times 32 = £7 \text{ 6s. 3d.}$$

12 = number of hours worked by locums.
60 = "normal working hours."
 $\frac{8}{7}$ = number of weeks sick.

It will be seen that the amount paid does not enter into the calculation. Presumably a full-time locum working at least 60 hours will attract the full £32. But of sheer necessity most of us can have only part-time help, as there are very few full-time locums available. Incidentally, it is interesting to note that our "normal working hours" are reckoned to be 60 per week.

I was completely deceived, and it is likely that others will have been misled too. I wonder if our negotiators realized the truth? If so, it is a pity that it was not publicized, because, once again, as in the whittling down of the 70% for ancillary help, this is likely to cause irritation and frustration. Finally, it is of great importance that those considering insuring against sickness, or possibly reviewing their present policies on the assumption that they will receive £32 per week, should realize the facts.—I am, etc.,

Harrogate, Yorks.

D. C. WILLIAMS.

Terms of Service—1805

SIR,—In the register of Wigtoft Parish Church in the county of Lincolnshire I found several references to the medical profession. One is reproduced below, and it reads as follows:

Vestry, Wigtoft, 30 April 1808.

The Churchwardens and Overseers of the Poor, were desired to contract with Messrs. Bishop and

fifteen Shillings for the Year, instead of twelve Pounds twelve Shillings.

In another, dated April 1807, it is stipulated "he is not to attend more than three women in childbirth, if he does, that he be allowed for such attendance one guinea each. That venereal cases be excluded. That he attend the poor at Kirton Holme belonging to

Page, of Kirton, Surgeons, Apothecaries, and Men-Midwives, for attending the Poor of the Parish of Wigtoft, and finding them Medicines, on the same terms as with Mr. John Pawson last Year, except that they are to have fifteen Pounds

the said Parish. But that his journeys do not exceed more than three miles from the town of Wigtoft.—I am, etc.,

Boston, Lincs.

G. R. USMAR.

Obituary Notices

Sir ADOLPHE ABRAHAMS, O.B.E. M.A., M.D., F.R.C.P.

Sir Adolphe Abrahams, consulting physician to Westminster Hospital and Hampstead General Hospital, London, died on 11 December after a long illness. He was 84.

[Walter Stoneman]

Adolphe Abrahams, son of Isaac Abrahams, of London, was born at Capé Town on 6 February 1883. He received his education at Bedford Modern School, where he was Exhibitioner, and at Emmanuel College, Cambridge, where he was Foundation Scholar and Prizeman. He took first class honours in the Natural Sciences Tripos in 1906, and went to St. Bartholomew's Hospital for his clinical studies, qualifying with the Conjoint diploma in 1909 and graduating M.B., B.Chir. two years later. He undertook further post-graduate study in Vienna, and proceeded M.D. in 1914. His first appointment was as house-surgeon at St. Bartholomew's Hospital, where also he edited the *St. Bartholomew's Hospital Journal*. From 1915 to 1920 he saw war service and was in charge of the medical division of the Connaught Hospital, Aldershot, and district consulting physician, Aldershot Command. He held the rank of major, R.A.M.C. and was mentioned in dispatches.

After demobilization Abrahams was appointed to the staff of Westminster Hospital in 1920, where he remained for the rest of his career. He retired in 1948, when he became honorary consulting physician to the hospital. At Westminster his influence was deeply felt in the medical school. He was in turn lecturer, tutor, and administrator in medicine, and dean from 1934 to 1940. He was also physician to the Royal Chest Hospital, and consulting physician to the Hampstead General Hospital, the Chislehurst, Orpington and Cray Valley Hospital, and the L.C.C. hospitals before these latter were taken over by the regional boards. He was examiner in medicine to the Universities of Cambridge and Liverpool, and examiner in medicine and applied pharmacology and therapeutics to the University of London. The Royal College of Physicians, of which he became a Fellow in 1930, appointed him censor. In 1951 he delivered the Lumleian Lecture to the College. He was a prominent member of the Association of Physicians of Great Britain and Ireland, and he had been president of the British Association of Gastro-Enterologists. With Sir Arthur Porritt he took a leading part in founding the British Association of Sport and Medicine.

Both medicine and athletics have lost a long-familiar figure by the death of Sir Adolphe Abrahams. The three brothers

Abrahams were renowned in the world of athletics. Adolphe Abrahams, the eldest of them, linked athletics with medicine in a life-long study. He acted as medical officer in charge of the British Olympic team at the various Games from 1912 in Stockholm to 1936 in Berlin, and after that at the European championships in Paris in 1938, and was also honorary medical adviser to the International Athletic Board. His interest in physical fitness was unbounded, and he once described it as "the provision of antidotes to the consequences of modern existence." He had some unorthodox ideas on the subject which he voiced particularly in his Arris and Gale Lectures to the Royal College of Surgeons in 1928 on the physiology of violent exercises. Among other things, he deprecated women entrants in big athletic contests. Physical vigour, in his view, might be purchased at an exorbitant price, at the sacrifice of certain moral qualities and advantages. He declared that all forms of violent exercise, especially when accompanied by the nervous tension of competition, tended to aggressiveness and to the disappearance of that softness which was identified with the charm of women. But for men he insisted on the value of athletic performance, even down to old age. He was one among several septuagenarians who were capable of running 100 yards in 12 seconds. He scoffed at golf for young men; it was an exercise, he said, for the middle-aged and elderly, especially for those mentally overworked and predisposed to introspection and melancholy. His own recreations included riding and motoring.

Alike in the stadium and in the hospital or classroom Adolphe Abrahams was a man to catch the eye. His spare figure, even when approaching old age, had something of the poise and grace of the Greek athlete. His physical endowments were matched by his intellectual qualities. His lectures and even his impromptu speeches in medical assemblies were models of what such things should be—examples of clear thinking, careful and often picturesque phrasing, and pleasant delivery. He was a master of the cogent simile and the faintly sardonic comment.

Abrahams wrote a good deal on general medical subjects, and was for some time editor of the *Postgraduate Medical Journal*. An early work of his, with the late Dr. G. Henschell, was on *Chronic Colitis*. He also produced, with Mr. A. Clifford Morson in 1921, a *Manual of Urinary Diseases*. Among other volumes were *Diseases and Disorders of Digestion* in 1931, *Training for Health and Athletics*, with H. M. Abrahams, in 1936, *The Human Machine* in 1955, *Disabilities and Injuries of Athletics and Sport* in 1960, and *Duodenal Ulcer and Other Alimentary Canal Disorders*, in 1961.

He was appointed O.B.E. in 1919, and was knighted in 1939. He married in 1922 Miss Adrienne Walsh, daughter of John Walsh of County Wicklow, and they had a son and daughter.

S. C. writes: My first recollection of Adolphe Abrahams is as an R.A.M.C. major applying for the vacancy of assistant physician to Westminster Hospital in 1920. His appointment coincided with that of two other Bart's men—Stanley Woodwork and Arnold Stott—all three destined to achieve distinction in the medical scene of London between the two wars.

Much has been said about Adolphe Abrahams as an athlete, and to this I may add two small points which may have escaped notice. When he was past middle age he had a portion of his radial artery excised, sent it to Sharpey-Schafer, and was delighted to get a report that the artery was that of a healthy young man. It was his practice up till the age of 70 and over to run round Regent's Park on Saturday afternoons, regardless of the weather, and it is reported that it was his habit to take his temperature during this exercise and that his performance improved as his temperature rose.

As a general physician he was most interested in fitness and health, and was somewhat cynical as regards ill-health. Both as a colleague, when called in consultation, and as a teacher this cynicism was obvious and was based chiefly on his philosophy that as we knew little enough about normal psychological problems we cannot "throw our weight about" as regards pathological states. He was an accomplished after-dinner speaker, a shrewd critic of the too readily accepted fads in medical practice, and somewhat inclined to rely on the *vis medicatrix naturae*.

The last few years of his life he put up with the physical disabilities of age, and referred to his bodily frame as "an antiquated Rolls-Royce—but still a Rolls-Royce." He was part of the medical scene of London, between the two world wars, and in many ways remarkable, liked by most, and respected by all who knew him.

W. E. L. writes: I remember Adolphe Abrahams's outpatient clinics with their large number of patients. Dr. Abrahams was conscientious in his attendance and never left the clinic, no matter how late the hour, until the last patient had been seen. He was an excellent clinician, and although his manner, from the patients' point of view, might appear rather detached, he took the greatest interest in their welfare. His chief interest was in diseases of the digestive tract, on which subject he wrote extensively, and he had a splendid command of the English language. Students will recall with pleasure his clinical teaching in his outpatient clinics, and later on his ward rounds when he became a senior physician. In fact Adolphe was always interested in students' activities, and often wrote in their journal. It was a great pleasure for him to witness the great strides which the Westminster Medical School had made from his early association with the hospital, and part of this success was due to himself as he was dean of the Medical School from 1934 to 1940.

At Cambridge he was a fine athlete, and throughout his long life he was a great advocate of adequate physical exercise. He did much to foster athletics in this and other countries, and he was medical officer to the British Olympic team on many occasions. In 1951 he delivered the Lumleian Lecture at the Royal College of Physicians, his subject being "Physical Exercise; its Clinical Associations."

Even when greatly advanced in years his boyish athletic figure, always most elegantly dressed, was the envy of his colleagues, and he will be remembered with affection.

G. MACDONALD, C.M.G., M.D.
F.R.C.P., D.P.H., D.T.M.

Professor G. Macdonald, professor of tropical hygiene in the University of London and director of the Ross Institute at the London School of Hygiene and Tropical Medicine, died on 10 December, at the age of 64.

George Macdonald, son of the late John Smyth Macdonald, F.R.S., was born on 22 June 1903. He was educated at the King Edward VII School, Sheffield, and entered the University of Liverpool, where after a distinguished undergraduate career he graduated M.B.,

Ch.B. in 1924 and took the D.T.M. the same year. From the early stage of his career Macdonald was attracted to tropical medicine. From 1925 to 1929 he was research assistant at the Sir Alfred Lewis Jones Laboratories in Freetown, Sierra Leone. He then spent two years

as a research officer for the Malaria Survey of India before returning to England in 1931. A year later he proceeded M.D. and shortly after took the D.P.H. After this he worked for five years as a medical officer for the Mariani Medical Association in Assam before his appointment as assistant director at the Ross Institute in 1937, where in 1945 he succeeded Sir Malcolm Watson as director. He had a distinguished service during the second world war when he was in turn commanding officer of No. 1, No. 2, and No. 3 Malaria Field Laboratories, and then consultant malariologist to the Middle East Forces and to the Central Mediterranean Forces.

After demobilization in 1945 with the rank of brigadier he resumed his work at the Ross Institute, and in the same year was also appointed professor of tropical hygiene at the University of London. He took the M.R.C.P. in 1948. He was appointed C.M.G. in 1953, and in 1954 received from the World Health Assembly the Darling Foundation Award for his studies on epidemiology of malaria. In 1955 he was elected F.R.C.P.

He was honorary consultant malariologist to the War Office, member of the World Health Organization Expert Advisory Panel on malaria and on environmental hygiene,

and leader of the 1952 W.H.O. mission to Korea. From 1953 to 1961 he was a member of the Colonial Medical Research Committee. He was chairman of the malaria committee of the Medical Research Council and a member of the Council's Tropical Medicine Research Board from 1961 to 1964, member of the managing committee of the Bureau of Hygiene and Tropical Diseases, and from 1965 to 1967 president of the Royal Society of Tropical Medicine and Hygiene.

The death of George Macdonald is a grievous loss to tropical preventive medicine generally and to malariology in particular. There are few people among the rapidly diminishing group of senior malaria experts whose impact on the strategy of control and eradication of malaria has been as great. There are even fewer whose scientific concepts of malaria epidemiology have been equally important, and among them no one can match George Macdonald's interest, enthusiasm, and experience in applying modern computer techniques to preventive medicine.

The mathematical models presented in a series of papers during the period 1952 to 1957, and in his 1957 book *Epidemiology and Control of Malaria*, gained immediate acceptance, because they provided a satisfying explanation of one aspect of malaria—namely, the variation of its epidemiological equilibrium. This equilibrium, very sensitive to changes in the mosquitoes' feeding pattern and longevity, has now been fully quantified and adapted to computer calculation, and is now being used for both the design and assessment of control programmes. The theory of malaria control was originally built up on a general basis, but found its confirmation and practical application in the course of field programmes assisted by the World Health Organization. From the very beginning of the global malaria eradication programme Professor Macdonald was closely associated with its planning. He participated in nearly every session of the W.H.O. Expert Committee on malaria, and the impact of his experience and personality are obvious in most of the relevant records. George Macdonald's recent work on assessment of the rate of reduction of the parasite reservoir indicates the possibility of forecasting the interruption of malaria transmission, and has been incorporated into the latest reports of the W.H.O. Expert Committee on malaria for field use.

His method of mathematical analysis has been extended to bilharziasis and a wonderful model devised, several characteristics of the snail vector being treated as parameters. The results of this study run on a computer showed such a striking similarity to the experience gained in the field that it could well be used as guide for various forms of control of bilharziasis.

Until a few weeks before his death George Macdonald worked on other mathematical models that could be applied to many insect-borne infections, and to immunization programmes for control of all types of communicable disease. About a year ago he knew that from then on he lived on borrowed time, but this did not greatly affect his decision to live as normally as possible, and to carry on with his research and teaching. To all those who were close to him during that time this lonely fight against an inexorable fate was a dramatic experience and an inspiring

example. He was a man of many talents and had a tremendous personality that commanded an immediate respect and admiration. A formidable opponent in a scientific discussion, he always listened carefully and weighed fully the argument that challenged his views. His manner could be aloof when he was preoccupied, but whoever worked with him or needed his help appreciated his quiet humour, his ability to understand others, and his infinite kindness. He was loved by his staff, who were intensely loyal to him and proud of his and their joint achievements. In international circles, where he was immensely respected, he represented the best tradition of British science and its applications to problems of tropical public health.

He is survived by his wife, whose affection and understanding helped him so much during all their married life, and by his son and two daughters, one of whom is a practising physician. We offer them our deep sympathy in their bereavement.—L. J. B.-C.

BÉLA SCHICK, M.D.

Dr. Béla Schick, the well-known paediatrician, died in New York on 6 December, aged 90. His name is inseparably connected with the test he devised in 1913 for estimating susceptibility to diphtheria; and among immunologists he will be remembered for the fundamental work he carried out with von Pirquet, in Vienna, in the early years of the century on the subject of allergy.

Béla Schick was born as a premature infant at Boglár, in Hungary, on 16 July 1877. He received his medical training at Graz, in Austria, where he graduated M.D. in 1894. He remained at the university till 1900, and then, after approximately a two-year period of military service in the medical division of the Austrian army, proceeded, like his great fellow-countryman Semmelweis before him, to the larger world of Vienna. There in the university and the children's clinic he worked in collaboration with Clemens von Pirquet and Theodor Escherich. In 1918 he was made professor of paediatrics. He retained this position till 1923, when he emigrated to the United States to take up a post that had been offered him at the Mount Sinai Hospital in New York. The rest of his life was spent in his adopted country, where he was naturalized in 1929. He practised as a consulting paediatrician in New York City. In this capacity he was attached among others to the Mount Sinai Hospital, the Sea View Hospital, and the Willard Parker Hospital; and later, from 1938 to 1942, was appointed clinical professor and lecturer in diseases of children at Columbia University. After his retirement in 1942 at the age of 65 he continued his paediatric work at the Bethel Hospital, in Brooklyn, and the Albert Einstein College of Medicine, where he acted as visiting professor.

Schick married in 1925 Catharine C. Fries, a doctor of jurisprudence. Though denied children of his own, he was intensely fond of children, and his ways with them are commemorated in a book *Béla Schick and the World of Children*, by Antoni Gronowicz, published in 1954. Every year, partly in response to a nostalgic home call, Schick spent two or three months in Europe attending paediatric congresses and renewing

acquaintances with friends and colleagues. For this purpose he kept an old open Ford car in permanent storage, which he picked up when he came over. He was fond of travelling, and it was on a South American cruise last month that he contracted pleurisy, from which he died shortly after his enforced return to New York.

Honours were showered upon him too numerous to name. Among them, however, was the Addingham gold medal awarded him at Leeds in 1938, and the Semmelweis medal of the American Hungarian Medical Society in 1955. To celebrate his 80th birthday papers by authors from different parts of the world were published in four successive numbers of the *International Archives of Allergy and Applied Immunology*, and later published in collected form as a Festschrift entitled *Current Problems in Allergy and Immunology*, edited by William Kaufman (S. Karger, Basel, 1959).

Schick came into prominence in 1905 when, with von Pirquet, at Vienna, he described the phenomenon of serum sickness. As has so often happened in similar circumstances, von Pirquet and Schick were not the first to recognize the disease. This had been done already in Lublinski in 1894, but it was they who coined the term "serum sickness." Schick's association with von Pirquet was most beneficial. They worked together in harmony and laid much of the foundations of our knowledge of allergy. Von Pirquet, in 1907, introduced his tuberculin scratch test; and, working along the same lines, Schick in 1913 introduced the skin test that bears his name. Though both tests are carried out on the skin, they are quite different in principle. The one is a test for delayed hypersensitivity to the tubercle bacillus, and when positive indicates the existence of infection. The other is a test for the presence or absence of serum antitoxin; it does not depend on allergy, and when positive indicates susceptibility to the diphtheria bacillus. The Schick test was taken up by Park and Zingher in New York, in 1925, as the basis of the city's programme to eliminate diphtheria. Thousands of children were tested, and much valuable information was obtained about the epidemiology of the disease. The original purpose of the test was to find out whether a child in contact with diphtheria needed to be passively protected by an injection of diphtheria antitoxin. Later, when neutralized toxin and toxoid preparations became available for active immunization, it was used to find out which children required immunizing. Now, with routine immunization of infants, all of whom after the disappearance of maternal antibody can be regarded as susceptible, the Schick test is no longer needed. Apart from epidemiological survey work and the testing of the antigenic potency of various prophylactic agents, its only use is to serve as a detector of hypersensitivity of older persons to foreign proteins in the toxin preparation—a purpose quite different from that for which it was originally intended.

In addition to allergy, Schick was interested in a variety of subjects mainly relating to infectious diseases of children. While at Vienna he wrote a book in 1912 on scarlet fever with his colleague Theodor Escherich—of *Escherichia coli* fame—and during his long life he wrote on tuberculosis, diphtheria, child care, and the nutritional problems of

children. He realized the danger of cross-infection to an infant admitted to the general ward of a hospital, and insisted on all infants under 1 year being nursed in isolation in special cubicles from which even the residents were barred. He put the welfare of his child patients before everything else, and their clinical care and treatment before research investigations. He will be remembered with affection and respect by medical and scientific workers throughout the world, and particularly by those who had the privilege of sitting under him as a teacher. —G. S. W.

A. R. S. VICKERS, C.M.G., O.B.E.
M.B., CH.M.

Dr. A. R. S. Vickers, medical superintendent of the Royal Flying Doctor Service of Australia, Queensland Section, died at Cape Town, South Africa, on his way back to Australia from England at the end of October. He was 66.

Allan Robert Stanley Vickers was born on 3 June 1901, and received his medical education at the University of Sydney, graduating M.B., Ch.M. in 1926. He was appointed resident medical officer at Albury Hospital in 1927, and in 1931 was recruited as medical officer to the Flying Doctor Service by its founder, the Rev. John Flynn, of the Australian Inland Mission. He served with the Flying Doctor Service in many parts of Australia, becoming in 1935 the medical superintendent and controller of bases at the Queensland Section. During the second world war he served with the Australian Army Medical Corps as officer commanding the 110th Australian Military Hospital. For much of this period he was vice-president of the West Australia Section of the Flying Doctor Service. After being discharged in 1943 with the rank of lieutenant-colonel he returned to his duties with the Flying Doctor Service in Queensland, where he opened a new base at Charleville, remaining there until 1954. In addition, he was appointed senior medical officer of the Queensland Section, and was closely associated with the establishment and supervision of new bases. In recognition of his services he was appointed O.B.E. in 1951 and C.M.G. in 1955. In 1955 the Flying Doctor Service was granted permission to use the prefix "Royal."

Dr. Vickers, who came to Britain in 1954 under the auspices of the Nuffield Foundation to undertake postgraduate study and to stimulate interest in the flying doctor services in the Commonwealth countries, again visited Britain in 1967, this time in a private capacity to attend the wedding of his son—also in the medical profession. It was on the return journey by sea to Australia that his death occurred.

In 1934 he married Lillias Whitman, and they had two sons.

N. A. D. writes: From the early thirties until his death Dr. Allan Vickers had been for most Australians the epitome of the "Flying Doctor." In the years of drought and depression he voluntarily cut his salary while refusing to allow the Flying Doctor Service to be curtailed, and then was sent by the founder, "Flynn of the Inland," on a lecture tour of the Australian cities that put the service back on its feet. It was in London

during 1954 that I met Allan, and his enthusiasm took me to Queensland as a flying doctor. His support and encouragement helped to see a Flying Doctor Service started in Nigeria, and at the time of his death he was helping initiate a service in Ethiopia. His death is a loss both personal and to the Services in Australia and Africa.

BESSIE M. PLAYFAIR, M.D., D.P.H.

Dr. Bessie M. Playfair (née Davidson), formerly medical officer in charge of the V.D. department at the Royal Free Hospital, London, died in Dundee Royal Infirmary on 21 November. She was 70.

Bessie Morrison Davidson was born on 13 December 1896, and received her medical education at St. Andrews University, graduating M.B., Ch.B. in 1920 and proceeding M.D. three years later. She took the D.P.H. in 1930. After holding several appointments in Scotland, including that of medical officer to the public health department at Dundee, she came to London in the late 1930s to take up an appointment in the venereal diseases department of the Royal Free Hospital, becoming medical officer in charge of the department in 1957. She was also part-time medical officer to the public health department, Deptford, and to the women's welfare centres in North Kensington and Goswell Road, London. In addition, she was medical officer in charge of the special clinic at the Mothers' Hospital in Clapton, which was run by the Salvation Army. She retired in 1960.

M. R. writes: Dr. Playfair came to London from Dundee, where she had been doing antenatal and V.D. work, to be second assistant of the V.D. department at the Royal Free Hospital, and eventually became director of the department. She did valuable work there, being a keen, hard-working Scots-woman, devoted to her work and to her patients. On retirement she went to Plympton, Devon, to be near her son—also in the medical profession—and her grandchildren.

J. S. writes: I first knew Dr. Playfair in 1945 when she was senior assistant in the department of venereology at the Royal Free Hospital. She was also in charge of the special clinic at the Salvation Army's Mothers' Hospital at Clapton and visiting venereologist at Avalon approved school. In 1957 she became the medical officer in charge of the clinic at the Royal Free Hospital, retiring in October 1960. She was an excellent venereologist, and much beloved by her patients, however difficult they might be. Her delightful sense of humour was never at a loss in dealing with difficult situations. For many years she lectured in her special subject to pupil midwives at the Royal College of Midwives.

A. CAMPBELL HILL, M.A., M.B., CH.B.

Dr. A. Campbell Hill, for many years a general practitioner in Kensington, died at his home in Hove on 15 November after a long illness. He was 72.

Alexander Campbell Hill was born in Aberdeen on 17 October 1895. He was educated at Gordon's College and Aberdeen

University, graduating M.A. in 1914. His medical studies were interrupted during the first world war by service with the Gordon Highlanders in France, where he was wounded and sent home. He completed his medical course, graduating M.B., Ch.B. in 1918, and immediately joined the R.A.M.C. and was sent out to Mesopotamia.

After demobilization with the rank of captain he started in general practice in Tottenham, at the same time working at the Prince of Wales' Hospital and the Chelsea Hospital for Women. He obtained a diploma in ophthalmology, a subject in which he was particularly interested, and he worked at the Western Ophthalmic Hospital. In 1931 he moved to Kensington, where he remained until he retired in October 1964.

Campbell Hill belonged to that school of family doctors who, by unremitting devotion to their professional work, earn the whole-hearted trust and affection of their patients. He was an excellent practitioner, and always kept himself fully up to date with medical progress. He was more than usually self-sufficient, taking his own x-rays, doing his own clinical side-room work, and maintaining an exceptional expertise in ophthalmic work. He had a quiet and unassuming manner, appearing never to hurry; but no one was more alert and observant, or quick in an emergency. He had few interests outside his work and his family life. He read widely, and had a well-stocked and orderly mind. Very much a Scot, with the gentle enunciation of his northern origins, he did not seek companionship; but those of us who had the privilege of knowing him and enjoying his kindly friendship are grieved that he did not live longer to enjoy his well-earned retirement.

He married in 1924, and is survived by his wife and one son, who joined him in his practice.—J. D. W. P.

T. E. S. LLOYD, M.A., M.B., B.CHIR.

Dr. T. E. S. Lloyd, one of the senior medical practitioners in Luton, died suddenly at his home on 5 December. He was 59.

Thomas Edmund Seymour ("Tom") Lloyd was born in Luton on 11 October 1908, and was educated at Uppingham and Queens' College, Cambridge. His clinical years were spent at St. George's Hospital, London, where he qualified with the Conjoint diploma in 1932, and held early resident appointments. He proceeded to M.A. in 1934, and graduated M.B., B.Chir. in 1937. He joined his father's practice in Luton in 1935, and remained in general practice until his early retirement in 1966. For more than 30 years he was a popular, kind, diligent, and highly esteemed family doctor. His patients found in him not only a medical adviser but a friend and counsellor. Respected by his medical colleagues he played a leading role in many medical activities. He was chairman of the South Bedfordshire Division of the British Medical Association in 1953, and for many years was a member of the social committee, devoting much of his spare time to B.M.A. affairs. His fondness for children and experience in paediatrics led to his appointment to the children's annexe of the Luton and Dunstable Hospital as assistant physician, and later as clinical assistant.

In addition to his dedication to medicine, Dr. Lloyd had wide interests in many other spheres. He was a most talented musician, and not only did he compose and produce the exceedingly popular cabarets for the annual B.M.A. dinner but also, in a more serious vein, composed church music, one of his compositions being recently played as a hymn in the Luton Parish Church. He was an enthusiastic supporter of local government affairs and served on the Bedfordshire County Council, of which he later became an alderman, for a period of 12 years. One of his lesser known hobbies was collecting wild flowers, and he was most knowledgeable on this subject. His reticence about his own abilities was in keeping with his modest demeanour. During the last five years he had bravely faced two serious illnesses, and it is sad and ironic that shortly before his untimely death he had apparently regained his former health and vigour. It is hard to think of medical practice in Luton without Dr. Lloyd in our midst, and to his widow and five children we extend our very deepest sympathy.—T. P.

K. M. FOSTER, M.R.C.S., L.R.C.P.

Dr. K. M. Foster, formerly in general practice at Ancaster, near Grantham, Lincolnshire, died at his home on 28 October. He was 65.

Kenneth Macdonald Foster, the son of a doctor, was born on 6 February 1902, and was educated at Oundle and Birmingham University, qualifying with the Conjoint diploma in 1927. He set up in practice at Worcester, where he became honorary anaesthetist at the Royal Infirmary. He was a founder member of the Worcester Rugby Football Club and a member of the cricket club. He worked undirigly, often operating late in the evening after a long day in his practice. In 1937 he moved to Ancaster. During the second world war he joined the R.A.M.C., and was medical officer in charge of two hospital ships in the Middle East, and was twice torpedoed. After demobilization with the rank of lieutenant-colonel he returned to his practice at Ancaster, and threw himself into his work and into the life of the village so energetically that by 1947 he had received the first warnings of the heart trouble that was to dog him for the rest of his life.

Kenneth Foster was a born committee man, and at various times served on the Grantham Hospital Management Committee, was secretary of the local medical committee, and vice-chairman of the National Health Service executive council. He was a founder member of the (now Royal) College of General Practitioners, and became at one time chairman of its council, having been a member of council since its inception. In 1959 he paid a visit to Australia as representative of the College, a trip which he found completely fascinating. The College was always one of his most cherished objects. He was provost of the North Midlands faculty of the College, and a member of the selection board of Sheffield University. He was largely responsible for starting the Ancaster branch of the British Legion in 1946, and was founder president, remaining in this office until his partial retirement about eleven years ago. A member of the British Medical Association, he was a

representative at the Annual Representative Meetings in 1930 and 1932, and again in 1951.

Kenneth enjoyed a number of hobbies. He kept a motor-cruiser on the Norfolk Broads; a caravan, in which he toured his beloved Highlands; and a market garden which he ran for some years in Ancaster. He loved shooting, but had to give this up because of his health. He will be missed by many as a kind and understanding personal physician, and by his colleagues, as well as his patients, for his wise and prudent counsel in many crises of their lives.

He leaves a widow and a son and daughter.—F. C. C.

J. W. LINNELL, M.C., M.D., F.R.C.P.

T. A. W. writes: Jack Linnell (obituary, 16 December, p. 686) and his brother Rob were second- and third-year men when I went up to St. John's, Cambridge, in 1902. Jack distinguished himself by getting a first in both the first and second parts of the Natural Science Tripos. When the first world war started he already had his foot firmly planted on the consultant ladder at the London Hospital. On the day after the outbreak of the war, however, he walked into the War Office and offered his services. He was accepted immediately, and was in France within a very short time. He was involved in all the major battles, choosing front-line duties in preference to consultant base duties for which he was well qualified. His bravery was recognized by the award of the Military Cross. For many years after the war he had a flourishing consultant practice in London, and made a special study of thyroid diseases, being a co-founder of the Thyroid Society.

His father was rector of Pavenham, Bedfordshire, and Jack read the lesson in his father's church from his undergraduate days until shortly before his death. He had a beautiful voice, and his reading was so much appreciated that one of his admirers made a recording of one lesson reading. Among his many distinguished friends were authors, including Francis Brett Young, and men in many different walks of life. He took great delight in entertaining them in his home.

B. W. P. writes: When he left his London consultant practice to spend week-ends in his lovely country home at Pavenham—so aptly named the Retreat—Dr. Jack (as he was affectionately called by the villagers) did not always leave his work behind. Local general practitioners were glad to call him in for consultation in their difficult cases, and Dr. Linnell would always give of his best. The time he spent with these patients would reveal to him not only their personal problems but many of their personal problems too. Few went away unhelped, and so he added to his already wide circle of friends. An avid reader, a wise countryman, an inspiring talker, and an even better listener, his Sunday teas gathered in a fascinating cross-section of people who were his friends. Those who are left will sadly miss his radiant personality and his true Christian charity, as well as regret the end of a long line of Linnells in North Bedfordshire.

News and Notes

MEDICO-LEGAL

Blood Tests and Paternity

[FROM OUR LEGAL CORRESPONDENT]

The Court of Appeal has affirmed the order of Mr. Justice Ormrod¹ directing the Official Solicitor to arrange for a child to be blood-grouped to assist in determining the child's paternity (*The Times*, 15 November). Both the child's mother, the mother's former husband, and another possible father had themselves consented to submit to a blood test.

The trial judge in making the order claimed to rely on the jurisdiction of the Court as custodian of the child. He held that that jurisdiction was unaffected by an earlier decision of the Court of Appeal that the Court had no power to order the parties to a suit to undergo blood tests.

The judges of the Court of Appeal were divided about the reasoning employed to support Mr. Justice Ormrod's decision. Lord Denning held that the Court had the power to direct that a blood test be done on a child

in custody proceedings, in a paternity suit, or in a divorce action based on the ground of adultery. But Lord Justice Willmer and Lord Justice Davies, while supporting the judges' decision on the particular facts of the case, held that the jurisdiction existed only in proceedings concerning custody of a child, and not in paternity or divorce suits.

Strong views are held on this subject. While some favour the use of all available forms of evidence, even if compulsion is necessary, others see blood tests as an invasion of personal liberty and a significant step along the road to totalitarianism. But fears that the courts will not know where to draw the line show a distressing lack of confidence. It is perhaps not insignificant that the trial judge in this case is medically qualified.

Dangerous Patients

[FROM OUR LEGAL CORRESPONDENT]

Once again concern has been expressed from the Bench at the release from a mental hospital of a man who subsequently committed a crime.

On 31 October at Lincolnshire Assizes a man aged 25 pleaded guilty to manslaughter on the grounds of diminished responsibility in respect of a 65-year-old woman. The woman was stabbed to death two months after the man had discharged himself from a mental hospital.

Replying to an inquiry from the Assize Judge, a prison medical officer said that he understood that the man, who had suffered from mental illness for some time and had been treated at Rampton Hospital, had been considered to have improved sufficiently to be transferred from strict supervision to another hospital, where he had been treated as an informal patient.

An order was made committing the man to Rampton Hospital indefinitely.

EPIDEMIOLOGY

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending 2 December (No. 48) and corresponding week 1966.

Figures of cases are for the countries shown and for Greater London. Figures of deaths and births are for the whole of England and Wales (London included), Greater London, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

PARLIAMENT

Questions in the Commons

[FROM OUR PARLIAMENTARY CORRESPONDENT]

Devaluation and Government
Expenditure

Mr. M. MACMILLAN (Farnham, Con.) asked the Minister of Health on 11 December what additional funds were to be made available to maintain the hospital building programme in view of rising costs as a result of devaluation.

Mr. ROBINSON said that the effect of devaluation on Government expenditure was still under consideration and it was too early to make a statement.

Mr. P. DEAN (Somerset, North, Con.) drew the Minister's attention to the fact that there had already been a cut—last year—of £3m. on local authority capital programmes. Unless more money was made available, he said, the Minister's plans for local authority services would fall even further behind his original plans.

Mr. ROBINSON: "It is not expected that devaluation will result in costs of the local authorities' capital programmes rising by all that much, or, indeed, very rapidly."

Mr. P. HOLLAND (Carlton, Con.) asked for a categorical assurance that rising costs would not cause any delay in the establishment of the university hospital in Nottingham.

Mr. ROBINSON said he was unable to give a categorical assurance while the matter was under consideration.

Dr. J. DUNWOODY (Falmouth and Camborne, Lab.) asked whether, in view of suggestions that there might be cuts in expenditure on the Health Service, the Minister would assure the House that he would resist any efforts to reduce expenditure not only on the hospital building programme but on the Health Service as a whole.

Mr. ROBINSON replied that he would take note of what had been said.

Treatment Centres for Drug Addicts

Mr. J. TILNEY (Wavertree, Con.) asked the Minister of Health what he was doing to expedite the setting up of treatment centres for drug addicts and whether special funds would be granted to regional hospital boards for the purpose.

Mr. ROBINSON informed him that additional facilities for the treatment of heroin addiction were being set up as quickly as possible, mainly in the London area. His department, he said, was in close touch with the hospital authorities. The cost was not expected to be very large in relation to the funds available to regional hospital boards. Consideration was given to any case of difficulty.

He added, in answer to another question, that outside London there was no evidence that current demand for treatment was not being met. This was very largely a London problem.

Mr. M. LIPTON (Brixton, Lab.) asked the Minister if he was aware that facilities in the London area for the treatment of drug addicts were "woefully inadequate." Could the Minister say what they were likely to be within the next few weeks?

Mr. ROBINSON said that he did not accept that they were woefully inadequate. "We have not yet completed the total of facilities which we want to be available for the time when the new arrangements come into operation." At the end of October, he said, there were about 70 patients receiving inpatient treatment and 180 receiving outpatient treatment for heroin addiction in some 40 hospitals.

Mr. W. DEEDES (Ashford, Con.) asked the Home Secretary when he expected to publish the necessary regulations under the Dangerous Drugs Act, 1967.

Mr. J. CALLAGHAN said in a written answer on 11 December that he aimed to make the regulations about notification early in the new year and those about prescribing in the spring. "I hope to consult the medical profession on these regulations shortly."

Doctors Returning from N. America

Mr. A. DAVIDSON (Accrington, Lab.) asked the Minister of Health if he had received the report of the board which recently visited the United States and Canada to interview British doctors who had expressed interest in returning to National Health Service practice.

Mr. ROBINSON: "Yes, and I am considering the best way of making these comments available for publication. The board found a substantial number of British doctors now working in North America anxious to return to this country. Arrangements for the return of some 50 doctors are well advanced and the number ultimately returning is likely to be higher. In the light of the report I shall consider further action to diminish the loss of British doctors through emigration."

Industrial Deafness

Dr. M. P. WINSTANLEY (Cheadle, Lib.) asked the Minister of Social Security on 4 December if she would add industrial deafness to the list of conditions qualifying for benefit under the industrial injuries scheme.

Mr. C. LOUGHLIN, Parliamentary Secretary: Before industrial deafness can be prescribed for industrial injuries benefit purposes the requirements of Section 56 (2) of the National Insurance (Industrial Injuries) Act, 1965, have to be satisfied. The large-scale Government research project into the effects of industrial noise, which is aimed at resolving the issues involved, should be completed in July 1968. Until its results become available the Minister cannot come to any conclusions on the question of prescription.

Pay-bed Revenue

Mr. PAUL DEAN (North Somerset, Con.) asked the Minister of Health on 5 December what was the total revenue from Section 5 beds and Section 4 beds, respectively, in the latest year for which figures were available.

Mr. K. ROBINSON: For the year ended 31 March 1967 the totals for England and Wales were: Section 5, £6,100,375; Section 4, £342,482.

Sale of Quinine

Mr. E. LUARD (Oxford, Lab.) asked the Home Secretary on 12 December whether he had yet taken a decision on the recommendations of the Poisons Board concerning the sale of quinine.

Mr. J. CALLAGHAN, in a written reply, stated: "The Poisons Board has considered representations against its earlier recommendations concerning quinine, and is reporting to me shortly. Further consultations may be necessary, but I wish to bring this matter to a conclusion as soon as possible."

Centralization of Operations

Mr. P. WOLRIGE-GORDON (Aberdeen, East, Con.) asked the Minister of Health on 13 December whether he was satisfied that the increasing centralization of operations, including minor operations, in large hospitals was still in the interests of the rural population.

Mr. ROBINSON: "There is no doubt that the most effective service can be given in large hospitals based on large catchment areas and able to offer a wide range of facilities. My policy is therefore, as stated in Cmnd. 3000, to provide a network of district general hospitals of this type. Planning will, however, take into account the communications problem in scattered rural areas."

Heroin and Cocaine Prescribing

Sir MYER GALPERN (Glasgow, Shettleston, Lab.) asked the Minister of Health on 13 December what inquiries were made by his department before doctors were authorized to prescribe heroin and cocaine to drug addicts; and what was the number authorized to do so.

Mr. ROBINSON: "Pending new regulations under Section 1 of the Dangerous Drugs Act, 1967, all doctors may prescribe heroin and cocaine unless their authority to supply and administer these drugs has been withdrawn by the Home Secretary following conviction for an offence against the Dangerous Drugs Act, 1965, or certain sections of the Customs and Excise Act, 1952. The question of preliminary inquiries therefore does not at present arise."

Pay-beds in Scotland

Mr. W. BAKER (Banff, Con.) asked the Secretary of State for Scotland on 13 December how many pay-beds were currently available in each of the regional hospital board areas of Scotland; and how many were available in 1964 and 1951.

Mr. W. ROSS, Secretary of State, gave the following figures in a written answer:

Region	Available Private Pay-beds in Scotland		
	1951	1964	1967
Northern ...	15	14	14
North-eastern ...	141	67	64
Eastern ...	196	115	116
South-eastern ...	140	50	50
Western ...	435	369	327
Scotland ...	929	615	571

Questions in the Lords

Breathalyser Tests

LORD NUGENT OF GUILDFORD (Con.) asked the Government on 11 December how many drivers had been required to submit to a breath test in connexion with the new drink and driving laws and the reasons why, indicating how many had been involved in accidents; how many were alleged to have committed traffic offences; and how many were suspected of having alcohol in the body.

LORD STONHAM, Minister of State, Home Office, said that during the period 9 to 31 October the police in England and Wales required breath tests under Section 2 of the Road Safety Act, 1967, in 2,724 cases. In 811 cases the person concerned was suspected of having been driving or attempting to drive at the time the vehicle was involved in an accident; in 1,049 cases of having committed a traffic offence while the vehicle was in motion; and in 864 of having alcohol in his body. These categories were not mutually exclusive, however. Chief officers of police believed that nearly all the drivers recorded as having been required to take the test because of a moving traffic offence were also suspected of having been drinking.

LORD NUGENT OF GUILDFORD also asked for the numbers of drivers who had been required to go to a police station for a blood or urine test; and the numbers of such cases in which it had subsequently been discovered that the blood alcohol level was not in excess of the prescribed limit.

LORD STONHAM said that in 927 of the 2,724 cases the driver was required to provide a blood or urine specimen for a laboratory test. Of 729 blood specimens analysed the forensic science laboratories reported 157 as being below the prescribed limit; of 96 urine specimens analysed 11 were reported as being below the equivalent level.

LORD NUGENT OF GUILDFORD asked whether Lord Stonham thought that 157 out of 927 was a "rather high proportion" of breathalyser tests which showed a positive reaction yet on blood or urine tests showed that the accused person was innocent.

LORD STONHAM said he did not agree. "There always must be a time lag," he said, "between a person's taking a breath test which shows a content above the level and his then going to a police station, taking a second breath test, having a doctor summoned, and having a blood test sample taken. During the passage of an hour there can be a fall of from 10 to 20 mg. of alcohol content per

100 ml. of the blood. Then, when the samples of capillary blood are taken there is the chance of some evaporation. Containers may not be firmly fixed down, and there may be some further evaporation. And finally, with the extremely accurate tests taken at the laboratory—several are taken and the results averaged—in cases where the blood content is less than 100 mg. per 100 ml., 6 mg. are deducted, which is three times the normal margin of error, and where it is over 100 mg. per 100 ml. 6% is deducted. So there is a great bias in favour of the person who is being tested. Indeed, after the second test, when it still shows evidence of being above the equivalent level, there is in many cases no prosecution by the police."

Points from Parliament

► The number of staffed beds in the hospital service on 30 June 1967 was 467,907. In 1964 it was 471,961. The number of patients on waiting-lists at inpatient departments was 540,876 on 30 June 1967. In 1964 it was 491,488. (Minister of Health, 4 December.)

MEDICAL NEWS

M.R.C. Appoints New Secretary

Dr. J. A. B. GRAY has been appointed by the Medical Research Council to succeed Sir HAROLD HIMSWORTH, F.R.S., who will retire from being secretary of the Council next year. Dr. Gray is 49, and has been immediate deputy and alternate to Sir Harold since May 1966.

Cox Chair of Anatomy, Oxford

Dr. D. A. T. DICK, lecturer in anatomy at Oxford University, has been appointed to the Cox chair of anatomy. Dr. Dick was educated at Hillhead High School, Glasgow, and Glasgow University, where he graduated M.B. in 1949. After service in the R.A.M.C. he was appointed demonstrator in anatomy at Glasgow in 1953. He moved to Oxford University in 1955, being awarded the degree of D.Phil. in 1958. From 1958 to 1959 he was a Carlsberg-Wellcome Research Fellow at the Carlsberg laboratory, Copenhagen. Returning to England he became Junior Research Fellow of Merton College, Oxford, and was appointed to his present post. He was elected a Fellow of St. Cross College, Oxford, in 1965. His book on *Cell*

(B. J. Harris)

Water was published in 1966. During the academic year 1966-7 he was visiting professor of physiology at Duke University, Durham, North Carolina.

Glasgow Honours Professor

Professor W. F. ANDERSON, who holds the David Cargill Chair of Geriatric Medicine at Glasgow University, has been awarded the St. Mungo Prize. The prize (£1,000 and a medal) is awarded every three years to the person judged to have done most to make Glasgow more beautiful, healthier, or more honoured. Commenting on the award, Professor Anderson said it was a tribute to the voluntary workers among the elderly.

1966 Census

Nearly a third of Great Britain's 53 million population lives in south-east England, according to the 10% sample census of England, Wales, and Scotland taken in 1966. The summary results were published this week (*Sample Census 1966, Great Britain, Summary Tables*, 1967, H.M.S.O., 32s. 6d. net). People born outside the British Isles numbered 1.9 million (compared with 1.5 million in 1961), 1 million in the Commonwealth and 0.9 million outside it. Household amenities were found to have improved since 1961. In the present census the proportions of households with the stated amenities were as follows (with 1961 figures in parentheses): exclusive use of own hot water 86% (76%),

Mr. R. V. Cooke, President of the B.M.A., in Helsinki with Dr. Väinö Pensala (right), Secretary of the Finnish Medical Association. Mr. Cooke addressed Finnish doctors at the opening session, on 19 November, of the F.M.A.'s Medical Week.

exclusive use of a fixed bath 80% (73%), and exclusive use of an inside water-closet 77% (1961 figure not available). Of the 17 million households in Great Britain 7½ million (45%) had at least one car, and 1 million (6%) had two or more cars.

Renal Transplantation under N.H.S.

The Minister of Health, Mr. KENNETH ROBINSON, announced in a written answer on 14 December that an Advisory Committee on Renal Transplantation had been appointed with the following terms of reference:

"To advise the Minister of Health and the Secretary of State for Scotland on the development of renal transplantation under the National Health Service, and in particular to examine and advise upon any proposals to establish renal transplantation units at new centres."

The members of the committee are: Professor Sir HEDLEY ATKINS, P.R.C.S. (chairman), Professor J. R. BATCHELOR, Professor D. A. K. BLACK, Professor R. Y. CALNE, Professor H. E. DE WARDENER, Professor A. W. KAY, Professor R. MILNES WALKER, Professor W. S. PEART, Professor R. SHACKMAN, and Professor M. F. A. WOODRUFF.

Cancer Studies in Birmingham

The Birmingham branch of the British Empire Cancer Campaign has reviewed its arrangements with the University of Birmingham for the conduct of research in the B.E.C.C. laboratories adjacent to the Queen Elizabeth Hospital and the Medical School. The branch will put an annual sum of money at the disposal of the university for the staffing and maintenance of the laboratories, which, subject to the approval by the branch of the general research policy to be followed, will then be administered by the university.

Instead of being, as hitherto, under the direction of the professor of pathology as honorary director, the laboratories will be in the charge of a full-time director, to be appointed. The university will shortly advertise a new chair of cancer studies, combined with the directorship. The intimate association of the laboratories with the department of pathology will be replaced by a broader association with the division of pathological studies in the medical school (comprising morbid anatomy, experimental pathology, virology, and other subjects). No firm decision has been taken on the area of cancer studies into which the laboratories will be expected to move: the faculty has in mind an approach through molecular biology, through immunology, through genetics, or through cell experimentation, but other approaches are not excluded.

British Association of Otolaryngologists

At the annual general meeting of the British Association of Otolaryngologists on 1 December the following were elected officers of the association for 1967-8: *president*, Mr. J. ANGELL JAMES; *vice-president*, Mr. G. H. BATEMAN; *honorary treasurer*, Mr. IAN G. ROBIN; *honorary secretary*, Mr. D. RANGER.

M.I.A. Dinner

The Medical Insurance Agency held a dinner in the Great Hall at B.M.A. House on 14 December to celebrate the Agency's diamond jubilee (see p. 696). Mr. A. M. A. MOORE, F.R.C.S., chairman of the M.I.A., presided, and the guests included representatives of the medical charities it supports and of the insurance companies with which it deals. Dr. RONALD GIBSON, chairman of the

B.M.A. Council, proposed the health of the M.I.A., Mr. MOORE responding. Mr. N. V. P. SEAL, the Agency's general manager, toasted the guests, and Mr. G. H. BATEMAN, F.R.C.S., honorary treasurer of the Royal Medical Benevolent Fund, replied. Between and after the speeches there were carols by the Consortium Medicum from Guy's Hospital.

Anniversary Exhibition

Charing Cross Hospital is to celebrate its 150th anniversary next year by holding a special week beginning 13 May. An exhibition illustrating past history is now being arranged. Readers who have photographs, records, or other items of interest and are willing to lend them for the period of the exhibition are invited to communicate with the House Governor.

Guild of Medical Bell Ringers

At the annual meeting of the Guild of Medical Bell Ringers, held in London on 18 November, the following were elected officers: *president*, Dr. J. B. WILLIAMSON; *master*, Dr. P. A. F. CHALK; *secretary*, Dr. D. L. GULLICK.

Services for the Disabled in Edinburgh

The Edinburgh Committee for the Co-ordination of Services for the Disabled set up in 1964 now represents some 70 voluntary, statutory, and professional organizations working with the disabled in the city. A notable event last year was the showing of the committee's film, "Working Together," at the Congress in Wiesbaden of the International Society for the Rehabilitation of the Disabled. Another was the opening of a

Answers to Quiz (p. 740)

1. (a) An allergic alveolitis due to sensitivity to antigens in pigeon droppings. (b) Pulmonary aspergillosis acquired from the habit of French pigeon breeders of transferring grain directly from their mouths to the bird's mouth.

2. (a) A Dutch religious sect in Pennsylvania and Ohio, who live as far as possible uninfluenced by the modern world. Because of this isolation and intermarriage they provide valuable genetic information. (b) Abnormal sensitivity, usually in men, to unexpected noise or touch, which results in an uncontrollable motor reaction of jumping or hitting. (c) A form of pica in pregnant women, who develop a compulsive craving for clay. (d) Persons addicted to tomatoes, carrots, and other foods containing yellow and red pigments.

3. (a) William Marsden, 1796-1867. (b) Jean Baptiste Charcot, 1867-1936. (c) Gustav Giemsa, 1867-1948. (d) Marie Curie, 1867-1934. (e) Lord Lister, 1827-1912. (f) T. Lauder Brunton, 1844-1916.

4. (A) Tenovus Institute at Cardiff. (B) St. Christopher's Hospice, Sydenham. (C) Lister, Royal College of Surgeons. (D) Edward Trudeau; "Guérir quelquefois, soulager souvent, consoler toujours." (E) It has been slit to allow disinfection against the plague.

5. (a) Loss of the normal dorsal curve of the spine, giving the impression of cardiac enlargement and systolic murmurs. "Pseudo heart disease." (b) Progressive, painful spasm of muscles of unknown cause. (c) Attacks of somnolence occurring in excessively obese subjects, possibly due to carbon dioxide narcosis. Typified by Mr. Wardle's boy Joe in the *Pickwick Papers*. (d) Cor pulmonale, often resulting in sudden death.

6. (a) A form of mental defect associated with epilepsy, microcephaly, and uncontrollable laughter. (b) Tremor of the head due to a cyst of the third ventricle. (c) Facies associated with idiopathic hypercalcaemia, sometimes accompanied by aortic stenosis. (d) Babies, usually premature, covered at birth by a shiny membrane which eventually cracks and peels. (e) Certain inborn errors of amino-acid and fatty acid metabolism, such as maple syrup urine disease, the oasthouse syndrome, and disorders of methionine metabolism.

7. (a) St. Chad. (b) St. Apollonia—martyred by having her teeth pulled out and jaws broken before being burnt. (c) St. Agatha. (d) St. Wolfgang. (e) SS. Cosmos and Damian. (f) St. Valentine. (g) St. Luke.

8. They all cause an allergic alveolitis, of which farmer's lung is the best known. Puff balls (*lycoperdon*) are used as a household remedy for stopping nosebleeds, and the pulmonary disease has been called *lycoperdonosis*.

9. (a) Boston Inter-Hospital Liver Group. (b) Respiratory distress syndrome. (c) Serenity, tranquillity, and peace. The hallucinogen more powerful than L.S.D. (d) Endocardial fibro-elastosis. (e) Dynamic dysentery device—an electronic weapon that emits a low vibration which causes loss of control of bowel action, thought to be of potential value in riot control.

10. (a) *Tristram Shandy*—Laurence Sterne. (b) *The Surgeon's Daughter*—Sir Walter Scott. (c) *Le Médecin malgré Lui*—Molière. (d) *The Young Physician*—Francis Brett Young. (e) *The Citadel*—A. J. Cronin.

11. (a) Thrombophlebitis migrans—Armand Trousseau, 1801-1867. (b) Salaam spasms, a variety of infantile spasms—W. J. West, 1841. (c) Christmas disease, Hartnup disease.

recreational and social centre at Cameron House, the property of the Edinburgh University Settlement. In its report for the year the committee provides an analysis of 5,000 cases of disability on the central register, an increase of 856 on the figure for the previous year.

People in the News

► Dr. F. AVERY JONES is to succeed Dr. G. F. ABERCROMBIE, who retires from the chairmanship of the Emergency Bed Service Committee of the King's Fund at the end of the year.

► Professor G. F. MILLS has been appointed to the chair in biochemistry at the medical school, Auckland University.

News in Brief

During 1967 the Variety Club of Great Britain has raised £642,000 for children's charities. Among projects supported are centres for medical research.

Grants and Awards

Professor D. F. N. HARRISON, professor of laryngology and otology, London University, has received a grant of £12,391 from the Medical Research Council to carry out an investigation over three years into changes in the inner ear due to administration of ototoxic and cytotoxic drugs.

The department of psychiatry of Liverpool University has been awarded a grant of £13,484 by the Medical Research Council for a clinical investigation of acute schizophrenia. The grant will be held jointly by Professor C. A. CLARKE, professor of medicine, and Professor F. J. FISH, professor of psychiatry; and Dr. B. K. BROOKER, lecturer in the department of psychiatry, will conduct the investigation.

Coming Events

North Staffordshire Medical Institute and British Occupational Hygiene Society.—International symposium on health conditions in the ceramic industry, 27–29 March 1968, Stoke-on-Trent.

Cambridge University School of Clinical Research and Postgraduate Medical Teaching.—Meeting, "Growing Points in Paediatrics," 8–10 April 1968. Fee £7 7s. Details

and registration forms from the Secretary, the Medical School, Tennis Court Road, Cambridge.

Royal Society of Health.—Health Congress, 29 April to 3 May 1968, Eastbourne.

Societies and Lectures

For attending lectures marked ● a fee is charged or a ticket is required. Applications should be made first to the institution concerned.

Thursday, 28 December

ROYAL POSTGRADUATE MEDICAL SCHOOL.—4 p.m. Mr. P. Martin: Raynaud's Phenomenon.

Friday, 29 December

ROYAL POSTGRADUATE MEDICAL SCHOOL.—10.15 a.m. Professor R. S. Shackman, Mr. J. R. Batchelor, Professor W. S. Peart, Mr. W. J. Dempster: Profile on Renal Transplantation.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council on 14 December, with Sir Hedley Atkins, president, in the chair, the election of Professor Sir Robert Macintosh, of Oxford, to the Honorary Fellowship in the Faculty of Anaesthetists was reported.

The Mitchiner Medal for 1963 was awarded to Lieutenant-Colonel W. C. Moffat.

Mr. N. L. Rowe was appointed Webb-Johnson Lecturer for the period 1967–9.

Professor I. R. H. Kramer was appointed the Charles Tomes Lecturer for 1969.

The Hallett Prize for 1965 was presented to Dr. N. V. Perera, of the University of Ceylon.

The Begley Prize was presented to Dr. M. M. Bowen, of St. Bartholomew's Hospital Medical College.

The award of the Evelyn Sprawson Prize to Mr. J. B. Phillips was reported.

A Diploma of Membership was granted to W. P. Garson.

A Licence in Dental Surgery was granted to R. H. J. Milliner.

After the meeting the Cecil Joll Lecture was delivered by Professor R. Y. Calne, on "The present position and future prospects of Organ Transplantation."

Diplomas of Fellowship were granted to the following candidates:

J. W. Carter, D. T. Goradia, A. B. J. Miller-Williams, J. C. D. Plant, M. J. Hunter, E. R. Norton, N. C. Roles, D. Booth, A. C. Bird, R. C.

Correction

The Worshipful Society of Apothecaries of London (2 December, p. 540). The name of Mr. G. T. Willoughby Cashell was omitted from the caption of the picture of the Court in Session. Mr. Cashell was seated between Sir John Richardson and Dr. Peter Bishop.

Notice to Authors

When original articles and letters for publication are not submitted exclusively to the *British Medical Journal* this must be stated.

Correspondence on editorial business should be addressed to the Editor, *British Medical Journal*, B.M.A. House, Tavistock Square, London W.C.1. Telephone: 01-387 4499. Telegrams: *Aitology, London W.C.1.*

Authors wanting reprints of their articles should notify the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs.

Subscriptions

Members' subscriptions should be sent to the Secretary of the British Medical Association, B.M.A. House, London, or to the Scottish Secretary, B.M.A. Scottish Office, Drumshugh Gardens, Edinburgh.

Doctors who are not members of the B.M.A. can subscribe to the *B.M.J.* The rates for doctors resident in the United Kingdom and abroad are given on the first page of the classified advertisements. These include the rates for the Australian edition and the North American "Air Express," which are available to both members and non-members of the B.M.A.

Classified Advertisements

Doctors Abroad.—Copies of the appointment vacancies advertised in the *B.M.J.* can be sent by air mail on request. The minimum cost is 3s. per week, for which copies of vacancies in up to five sections of the classified advertisements will be sent. The cost of each further section after five is 1s. Orders for specific grades in any section cannot be accepted. Payment should be enclosed with the order.

Details of rates, etc., for classified advertisements appear on the first page of the classified section.

New Issues of Specialist Journals

Obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, London W.C.1.

Neurological Damage in Parturition: Minor damage is not necessarily detected by classical neurological examination. Standardized quantitative observations are suggested to reveal handicaps and facilitate rearing these infants (p. 763). Leader at p. 761.

Obstetric Analgesia: Assessment by anaesthetist, patient, and midwife indicate that 0.35% methoxyflurane is suitable for intermittent self-administration during labour (p. 767).

Oral Contraceptives: Undesirable menstrual side-effects of microdoses of chlormadinone diminished by addition of oral oestrogens (p. 771).

Pneumoconiosis: Gas transfer defect of lungs found in 10 out of 16 patients whose radiopacities were of pure pinhead type, but in none of 11 men whose opacities were micronodular in type (p. 772).

Febrile Illness in General Practice: E.C.H.O. virus type 3 incriminated as causative agent in a geographical epidemic, which mainly affected children (p. 774).

Intermittent Claudication: Calf muscle denervation gave encouraging results in patients with inoperable femoropopliteal occlusions (p. 776).

Gynaecomastia: Observed in 6 patients with chronic renal failure during early stages of regular dialysis treatment (p. 779).

Pyloric Stenosis and Blood Groups: Lowered incidence of group A demonstrated in 303 patients with infantile hypertrophic pyloric stenosis. Salivary ABH secretor status showed no significant difference from controls (p. 781).

Case Reports: Ureterosigmoidostomy and neoplasia (p. 783); Nail-gun fatality (p. 784).

Congenital Heart Disease: Clinicopathological Conference at Royal Postgraduate Medical School (p. 785).

Upper Alimentary Bleeding: Surgical management (p. 790).

School Health Service: Trial of using general practitioners (p. 797).

Health Centres: Conference of doctors working in them (p. 800). Leader at p. 759.

Nursing Services in General Practice: Letters (p. 803).

Requests for Abortion: Said to be increasing (p. 802).

C.C.H.M.S.: Debates Welsh area health board plan (*Supplement*, p. 89).

Board of Science and Medical Education: Chairman of Council's proposals (*Supplement*, p. 92).

Public Health Pay Dispute: Agreement reached (*Supplement*, p. 94).

Cardiac Transplantation

On 3 December Professor Christian Barnard and his colleagues replaced the heart of 55-year-old Louis Washkansky with that of a 25-year-old girl mortally injured in a road accident. On 21 December Washkansky died, apparently from pneumonia. It is worth noting that the rejection process itself can cause pulmonary disease, but according to press reports the disease was infective in the present case. After a necropsy showing that death was due to pneumonia Professor Barnard was reported¹ as saying that there was no clinical evidence to suggest that rejection played a part in the death, and there was no evidence for human heart transplants to be discontinued. Despite its sad conclusion this was an outstanding surgical feat by the staff of the Groote Schuur Hospital at Cape Town. It was the application to man of a technique which had before been tested in animals and was a courageous operation that was bound to be attempted sooner or later.

How do the problems differ from those of the transplantation of kidneys? Successful matching of the tissues of the donor and the recipient is much more crucial for transplantation of the heart than of the kidney. The kidney is a complex structure, but its function is secretory and a fraction of its potential function will suffice for life. The heart is a unique organ; its vital activity must not falter for more than minutes and there is no artificial substitute which can preserve life for more than a matter of hours. Ischaemic damage may be incurred during transfer of a kidney, but recovery of such tubular necrosis may be confidently awaited. Meanwhile the artificial kidney takes over. A rejection crisis may be surmounted in the same way. Even total failure of function leaves the patient little worse off, for he can return to the intermittent dialysis which had preserved his life before operation, and further kidney grafts can be attempted later.

The heart is a richly innervated organ, but transplantation brings about complete extrinsic autonomic denervation, resulting in near total loss of the myocardial stores of catecholamines.² If the heart is removed from a dog and then replaced (autotransplantation) this denervation may be only temporary, and signs of reinnervation may be found as early as 26 days after reimplantation. It has been shown that after one to three years the response to stimulation of the vagosympathetic trunk is normal, though the actual number of intact neural connexions is probably small if judged by the still depleted catecholamine content of the various chambers of the heart.³ Reinnervation of hearts transplanted from one animal to another seems far less likely, and so the physiological consequences of chronic denervation of the heart have been extensively studied. The exercise tolerance has been shown to be nearly normal in animals with hearts surgically denervated by Cooper's technique,⁴ and W. M. Daggett and his colleagues found that the work capacity of dog hearts 6 to 12 weeks after autotransplantation was remarkably close to that of normal hearts.⁵

Unlike the normal hearts which were studied, autotransplanted hearts utilized exogenous circulating catecholamines. This may be an important adaptation to cardiac denervation, for Daggett's team found no alteration in myocardial contractility after transplantation, though the weight of the heart increased, suggesting that its efficiency was reduced. The retention of fluid and the rise in blood volume which occur early after autotransplantation⁶ are unexplained by these studies. This pseudo-heart-failure may be due to the loss of afferent vagal impulses from atrial stretch receptors and is easily countered by diuretics. Daggett has concluded that the autotransplanted and denervated heart achieves a similar level of performance to the normal heart and that total denervation of the heart, with its concomitant depletion of myocardial stores of catecholamine, does not preclude successful transplantation. Thus the main barrier to successful transplantation of the heart in man seems to be the question of rejection. Further advances will depend on either better immunosuppressive drugs or more probably the perfection of tissue-matching techniques, so that donor can be exactly matched to recipient.

Over the past two years leucocyte antigen groups have gradually been defined. Antisera obtained from multiparous women, patients who have had multiple transfusions, and recipients of skin and kidney allografts have been characterized and can be used to test for leucocyte-group compatibility.⁷⁻⁹ So far no prospective studies have been reported, but a retrospective study of donors and recipients after renal transplantation between relatives has recently been carried out by F. T. Rapaport and his colleagues and has shown that there is a considerable correlation between good leucocyte-group compatibility and success of the graft.¹⁰ The success of some kidney grafts despite apparent leucocyte incompatibility, and rejection of others despite apparent compatibility, underlines the fact that tissue typing is still in its infancy, but even at this stage the success of kidney transplants should become more predictable.

If tissue antigens do have some degree of overlap cardiac homotransplantation (from one person to another) will certainly be practicable. Furthermore, tissue compatibility may exist between different species, so that heterotransplants (between species) may become possible. This would solve some of the ethical and logistical obstacles to homotransplantation that have been discussed.

The diagnosis of death first became a problem with the use of elective cardiac arrest during cardiopulmonary bypass, for until then the issue had been simple: a patient was dead when the heart stopped. But it is the brain which determines whether life continues. If cerebral function has been destroyed the patient is really dead, and the artificial preservation of tissue integrity by a machine does not alter the fact. The difficulties stem from the need to know for certain

whether cerebral damage is irreversible. Relatives of patients with irreparable brain damage have to give permission for organs to be removed, and it would be understandable if some at a time of great distress were hesitant over a request to remove a heart. The coroner's permission is also needed. The short period for which organs can be maintained in good condition outside the body greatly limits the possible scope of large-scale transplant surgery at present, but soon it will be possible to keep organs viable for up to 48 hours after removal, and organ banks will eventually be developed. Until that time there will inevitably be many more potential recipients than there are organs available. But during the next decade cardiac transplantation will probably begin to save lives.

Disease from Monkeys

Wild animals, particularly primates, imported either for sale as pets or for use in laboratories may introduce a wide variety of infections into Britain. A joint committee of the British Veterinary and British Medical Associations reviewed the problem in 1962, and a leading article in these columns¹ drew attention to the problem. The committee thought that legislation and proper quarantine arrangements to control the importation of wild animals (particularly primates) were essential, but that it would be necessary to collect more evidence of the hazard before a strong case could be made for official action probably requiring substantial public expenditure.

Occasional cases of herpes virus B encephalomyelitis due to monkey bites continue to be reported.² An imported monkey recently developed rabies in a laboratory animal house.³ But lately serious outbreaks of infection in Marburg, Frankfurt, and Belgrade have at last focused more official attention on this problem in many countries. Vervet monkeys (*Cercopithecus aethiops*) were imported from Uganda through London, and the shipment was divided between laboratories in Marburg and Frankfurt. An acute febrile illness with rash, varying degrees of lung and liver damage, gastrointestinal disorders, and a tendency to bleeding associated with thrombocytopenia occurred in about 28 persons who had had contact with blood or tissue of these monkeys, and 7 of them died. There were a number of secondary cases in hospital staff with some sort of contact with the blood of patients. At about the same time similar monkeys were imported (some through London) to Belgrade. There two cases of the disease occurred: one a veterinarian who carried out necropsies on monkeys which had died in quarantine, the other his wife. A full report of the disease is to be published in *Deutsche Medizinische Wochenschrift*.⁴

Transmission in man seems to be by contact with infected blood or tissue, and a limited experiment⁵ suggests that the agent may be able to pass through the skin. Thus on present evidence general spread of this disease from man to man is unlikely, but the risk of infection must be constantly borne in mind by those who work (or play) with recently imported monkeys and by medical and nursing staffs treating febrile illnesses in such people. In obscure febrile illnesses and especially in cases of encephalitis questions about contact with animals (especially monkeys) should always be asked.

Material from the German cases was sent to laboratories in various parts of the world, and the major investigation of the human material was carried out at the Microbiological Research Establishment, Porton, Salisbury, which has the best

facilities in Europe for safe research on dangerous infectious agents. A preliminary account of this work⁵ shows that the agent was successfully transmitted to guinea-pigs, to monkeys of two species, to hamsters, and to cell cultures of several types. In guinea-pigs and monkeys the disease resembled the human illness—severe damage to the spleen, liver, and lungs, and a marked tendency to bleeding. The general picture is probably of acute disseminated intravascular coagulation,⁶ which has a variety of trigger mechanisms, including infectious diseases. In the livers of guinea-pigs large numbers of intracytoplasmic inclusion bodies with the staining properties of rickettsias have been seen in parenchymal cells. Filtration experiments suggest that the agent is about the size of a rickettsia or a bedsonia, but surprisingly the disease is not ameliorated (in guinea-pigs or apparently in man) by chloramphenicol or tetracycline, and it grows in cell cultures in the presence of penicillin and streptomycin. Collaborating laboratories in Britain, Germany, the United States, Senegal, South Africa, and elsewhere have failed to find an antigenic relationship between this organism and about 200 viruses, several rickettsias and bedsonias, toxoplasma, or other micro-organisms. Electron-microscopy in both Britain and Germany shows that the organism is elongated and pleomorphic, but its precise nature has not yet been elucidated.

These outbreaks occasioned much surprise—but why? Scientists knowledgeable about the zoonoses have been predicting their occurrence for many years. Over 60 adventitious viruses have been recovered from monkeys used in laboratories, and only chance has dictated that the majority were of low or no pathogenicity for man. Moreover, the risk has been steadily increasing. Not only has the rate of importation risen rapidly but monkeys are being more and more widely used by research workers (other than microbiologists) who often know little about the risks, among them physiologists, psychologists, pharmacologists, and experimental surgeons. Furthermore, as the demand for monkeys increases, the trappers are driven further and further afield to satisfy it, and monkeys have to be obtained from areas where they have little if any contact with man and where medical services capable of recognizing the occurrence of sporadic and unusual infectious diseases are absent. Clearly, therefore, quarantine with careful veterinary and microbiological observation of imported monkeys should be enforced before they are released for general use except to vaccine manufacturers and some of the large organizations such as the Medical Research Council with experienced laboratory staff, which can and do perform this task for themselves. Most of the smaller laboratories do not and probably cannot have adequate facilities and staff, and it should be recognized that it will be expensive to provide central facilities on an adequate scale with the high standard of accommodation necessary for quarantine and the highly trained staff essential to run it. Until this is done, every imported animal must be handled as if it may be harbouring a dangerous infection. Potentially most dangerous of all are the monkeys, which can at present be sold as pets within a very short time of arrival, and though their quarantine can probably be achieved cheaply the provision of adequate legislation will be complex. There is also

a need for much better holding accommodation and supervision at airports and other points of import and trans-shipment, and voluntary organizations such as the R.S.P.C.A. cannot be expected to provide these. In transit at London Airport the vervet monkeys for Germany had some contact with other monkeys (one of them sick), with alligators, and with a large number of species of bird. Cross-infection under such conditions is an obvious possibility and has been suggested as the mode of infection of the vervets.

Perhaps the most important implications of the monkey disease itself are in the manufacture of vaccines, as it seems that kidney cultures from infected monkeys are likely to contain the agent. Clearly there is a paramount need (now being met) for sensitive tests to ensure that live vaccines do not contain it. But the broader question remains whether it is really sensible to make vaccines from the tissues of wild animals. Surely a thoroughly tested cell culture system would be safer. Tested diploid cells (not from neoplasms) will now receive serious consideration as substrates for vaccine production, though very careful control will be required to detect possible malignant changes and such infections as hepatitis viruses in them. The present tendency is to think mainly of human diploids, but the story of how scrapie was spread among sheep by using an inactivated sheep brain vaccine,^{7,8} the fact that slow viruses show considerable host specificity, and the lack of methods for detecting human slow viruses suggest that diploids of a species far removed from man may be safest of all.

Health Centre Explosion

In the past many doctors were attracted to general practice because it offered them freedom to organize their work in their own way. Today, owing to political and social pressures, among other things, this freedom has become relatively limited. Hence young doctors are reluctant to think of general practice as a satisfactory career unless it offers them job-satisfaction of another kind—that of having the means to practise the scientific medicine they were taught. Many measures are now helping to provide these means, among them an increasing formation of group practices, the use of appointment systems and ancillary workers, and the recognition of the need for training—both vocational and continuing—for general practice. Another measure is practice at a health centre, and, as was pointed out at a recent conference at the Ministry of Health of doctors working in health centres (see p. 800), it seems that we are on the verge of a health-centre explosion. At present no fewer than 180 are being built or are at an advanced stage of planning.

One of the principal fears has always been that a standardized form of health-centre practice would be imposed on doctors working in them. There is no evidence that this has happened. Speakers at the conference emphasized the importance of flexibility and of asking the help of the doctors concerned before final plans for a centre are drawn up. Indeed, every health centre built is still in the nature of an experiment whose results may answer many of the remaining questions. What is the optimum size of a centre? Should doctors work as one large team or as several small groups? How large should the auxiliary team be, and how can it be used to save the doctors' time without impairing the essential doctor-patient relationship? Should nurses be used for diagnosing and treating simple ailments?

¹² Wilson, D. R., Ruth, D., and Smith, W., *ibid.*, 1950, 60, 267.

Fortunately the principles of flexibility and experiment are being applied in practice. One speaker at the conference described a one-man rural centre, and another plans for one for 16 doctors. At one relatively remote centre there are good diagnostic facilities and consultant sessions, and at another neither of these is provided, since the district hospital is round the corner. At one centre some patients are initially seen by a nurse, and at another the doctors make it a rule to speak personally to every patient who telephones. At yet another centre a pilot scheme for reducing visiting by bringing the patients to the centre is to be tried. It is clear, however, that even more flexibility is needed. Many speakers complained of sudden large increases in their bills for maintenance and ancillary help, often without notice, and the boundary between local-authority and general-practitioner services in some centres is still too rigid.

Health centres are not the only means of providing facilities for good medical practice. There are a few privately built group-practice centres which look and work as well as any health centre. Nor do health centres necessarily have to be paid for out of public funds—that at Witney, near Oxford, was built with private money. Nevertheless, in future most of them are likely to be financed by the State in one way or another. For this reason alone it is important that experiments should continue. More medical students should be able to see medical practice at health centres. In particular at least one centre should be built adjacent to a district general hospital. Family doctors working there should have access to the hospital diagnostic services and to beds. And they would meet their consultant colleagues on equal terms.

Intra-arterial Chemotherapy for Recurrent Neoplasms

Systemic administration of cytotoxic agents is the most valuable form of treatment for the leukaemias and widespread lymphomas, and useful remissions are regularly achieved. In chorion-carcinoma many reports of cure are now on record. For most solid tumours, however, systemic chemotherapy is of limited value because the local action is overshadowed by its toxic effects, especially on the bone marrow and gastrointestinal epithelium.

C. T. Klopp and his colleagues¹ in 1950 pioneered the use of intra-arterial injection to localize the effects of cytotoxic agents in patients with cancer confined to one region. Almost a decade later O. Creech² and R. D. Sullivan³ and their colleagues elaborated the original simple injection technique along lines predicted by Klopp. They achieved intensification of the local effect combined with limitation of the general toxicity by two methods: either the affected region was perfused through an extracorporeal circulation, or when simple intra-arterial infusion of the drug was used an antagonist was given in the systemic circulation to block toxic effects on normal tissues.

All these workers reported much better regression of disease than that obtained with cytotoxic agents given by the conventional systemic route. Understandably, widespread interest and enthusiasm were engendered and a spate of published work followed. The early impetus is now subsiding and it is becoming possible to view the merits of intra-arterial chemotherapy in truer perspective.

Regional extracorporeal perfusion using a pump-oxygenator has achieved an established place in the management of

uncontrolled malignant melanoma confined to a limb.^{4,5} Worthwhile palliation and sometimes prolonged freedom from signs of local disease can be obtained, so that major amputation is seldom required; the complication rate is acceptably low.

Simple intra-arterial injection or infusion with or without a systemic antidote has been used most often in the treatment of cancer in the head and neck, though it is also of some value in the treatment of pelvic⁶ and hepatic⁷ tumours. In 1962 G. Westbury and his colleagues⁸ reported the results of treatment with intra-arterial methotrexate and intramuscular citrovorum factor in 26 patients with cancer of the head and neck which had recurred after surgery or radiotherapy or both. They noted only one worthwhile response and stressed the considerable morbidity and mortality associated with the method, and suggested that the sclerosing effect of previous irradiation on the vascular bed had impeded access of the agent to the tumour cells. H. J. Espiner and his co-workers,⁹ reporting their own experience, observed the best results in patients in whom chemotherapy was the primary form of treatment; the worst results were in those receiving chemotherapy soon after radiotherapy had failed. Others have since drawn similar conclusions.¹⁰ More recently S. Tindel¹¹ has described a trial of intra-arterial infusion in patients with recurrence of neoplasms after surgery or radiotherapy or both. More than half had tumours of the head and neck; the remainder suffered from lesions of the bowel, bladder, cervix, or liver. He concluded that real benefit was uncommon and that the substantial morbidity and mortality limited the use of the method as a means of palliation. D. F. N. Harrison¹² has attempted to reduce the dangers of intra-arterial therapy in certain types of cancer of the head and neck by giving short-term infusions under whole-body hypothermia. He makes the salutary comment that the treatment should not be worse than the disease.

For the time being the primary management of choice in localized cancer is surgery or radiotherapy or a combination of both. Intra-arterial chemotherapy may prove to be a worthwhile adjunct in certain instances where the orthodox weapons offer small hope of control. If so it should usually constitute the initial attack, since the operation and ionizing radiation each in its own way damages the vascular bed of the tumour. Any possible advantage in terms of control of the disease must be weighed against the very real dangers associated with the method. The indications for this treatment are broader in those parts of the world where radiotherapy is not available.

In the control or palliation of localized malignant disease recurring after operation or irradiation intra-arterial therapy has proved to be largely disappointing, disturbingly hazardous,

and burdensome to patient and doctor. If indicated at all, it should certainly be conducted by an experienced team and not by the occasional practitioner.

Clinical Lessons from Developmental Neurology

The Mental Health Research Fund lecture for 1967 was given by a developmental neurologist, Professor H. F. R. Prechtl (p. 763 of this week's *B.M.J.*), on the sequelae of prenatal and perinatal complications. Some people might think the choice of speaker and subject rather remote from the field of mental health. This is not the case, however, for it reflects an increasing awareness of the fact that neurological, behavioural, educational, and psychiatric problems in childhood and later years may all have their origins and first manifestations in the early months of life. The statistical data and carefully reasoned discussion of Prechtl's presentation contain important lessons about the mechanisms of neurological disturbances and the techniques of neurological examination in infancy.

Many consider that a newborn baby is either completely normal or patently the reverse. Linked with this view is the notion that if a baby does not come to notice as a result of the presence of obvious symptoms and signs then all is well and further examination is unnecessary. This may be true of the immediate future, but it is the more distant outlook that counts. The aim is that the child should have every chance of growing into a mentally and physically healthy adult. H. Knobloch and her colleagues¹ have challenged the correctness of the "all or none" concept. These workers suggested that there was a "continuum of neurological damage," ranging from gross defects to initial minor damage with later sequelae, and this hypothesis is strengthened by Prechtl's findings. If their view is correct then detailed neurological examination of neonates is necessary to detect those with less obvious lesions who may later develop other more serious defects. To do this we need to be sure that our diagnostic tools are sufficiently precise for the task.

Prechtl's observations show that our present clinical techniques are unsatisfactory. Comparing the results of his methods of examination with those obtained by classical neurological techniques, he found that, though all the babies considered abnormal by the classical methods also scored poorly in his examination, many babies who appeared to be normal on the classical type of examination had low scores in his examination and also developed later sequelae. Prechtl's technique² consists of a battery of quantitative observations made under strictly controlled conditions. This is time-consuming work which is not easily adapted to clinical practice. Nevertheless, it should be studied so that the routine neurological methods used in diagnosis may be improved.

Important applications arise from this work concerning the rearing of young babies. Some of the difficulties which commonly occur in the rearing of young babies are attributed to the inexperience or fault of the mother. Possibly there is a

neurological basis for them which a Prechtl type of examination might reveal. Moreover, these minor neurological disturbances may be sufficient to affect the early behaviour of the infant and impair the mother-child interaction. This important period of emotional development is already being studied extensively, and everyone concerned should take note of Prechtl's work.

The concept of the "at risk" infant, which was introduced by Sheridan³ to stimulate the early detection of handicaps, has been criticized because of the unsatisfactory criteria of risk.⁴ Those concerned with finding satisfactory criteria might consider Prechtl's work. He points out that adverse obstetric factors rarely occur singly and has assessed the influence of clusters of adverse factors, using a "risk score" in his analyses.

Prechtl's work also has several implications in research. In particular, he has shown the importance of carefully standardized quantitative methods in developmental neurological examinations and their use as a research tool. It is reassuring that in Britain these methods are already being studied and taught in our more progressive departments of child health.

Miliary Crohn's Disease

The diagnosis of Crohn's disease can on occasion be puzzling. Recently K. W. Heaton, C. F. McCarthy, R. E. Horton, J. S. Cornes, and A. E. Read¹ have drawn attention to a form of it which may give rise to difficulties. They describe three patients in whom at laparotomy the conspicuous finding was the presence of many tiny pale nodules on the serosal surface of the bowel. Tuberculosis was initially diagnosed in two of the patients and they were started on antituberculous therapy.

The distinction between Crohn's disease and abdominal tuberculosis is a matter of some practical importance, for corticosteroids might prove disastrous in tuberculosis inadvertently diagnosed as Crohn's disease. The great majority of the granulomatous lesions in the ileo-caecal region are due to Crohn's disease,² and it seems likely that many patients suffering from it were diagnosed in the past as having hyperplastic tuberculosis. Nevertheless, some modern physicians have described the occurrence of tuberculosis of the ileo-caecal region,^{3,4} so that the possibility of this disease being present cannot be excluded without full investigation.

Histologically, the serosal nodules of Crohn's disease consist of non-caseating granulomata with giant cells of Langhans's type present. Caseation is exceptional in Crohn's disease, whereas it is one of the characteristic features of tuberculous nodules. The granulomata of Crohn's disease are bacteriologically sterile, while those of tuberculosis usually yield tubercle bacilli on culture or guinea-pig inoculation.

One of the patients described by Heaton and his colleagues is of particular interest because the serosal nodules were numerous, though the intestinal wall was barely affected. The authors were then led to postulate that the granulomata are the dominant lesions in early subacute Crohn's disease, and the fact that they follow the lines of lymphatics supports the view that the first pathological changes occur in the

lymphatics. Moreover, they were hopeful that patients treated at this stage with corticosteroids might do well and the bowel wall escape any major damage. The particular patient was doing well on prednisone therapy at the time they wrote their article, but unfortunately in an addendum they have to report that widespread radiological changes of Crohn's disease appeared in the small and large intestine, though the patient remained symptomatically well.

Cerebral Angiomas

Once discovered, cerebral angiomas are much less likely to cause death from haemorrhage than are the commoner berry aneurysms of the circle of Willis and its branches. This is evident from the recent account by W. R. Henderson and R. de R. L. Gomez¹ of the natural history of these malformations, and they confirm the findings of earlier workers, notably H. J. Svien and J. A. McRae.² Indeed, J. M. Potter³ has drawn attention to a number of patients who lived for many years at relative peace with their lesions and often with little or no disability, particularly after receiving the sort of radiotherapy that was given 30 to 40 years ago. This did not, of course, prove that radiation was necessarily effective—most authors think that it is not—but it did show that it would have been unnecessary to have submitted those patients to operations carrying the mortality and morbidity prevalent in those days.

Any major operation of uncertain prophylactic value needs to be examined critically. Present techniques for the precise localization of these angiomas and the definition of their feeding and draining vessels (they nearly all have arteriovenous fistulae), together with modern neurosurgical and anaesthetic methods, enable the surgeon to operate on apparently formidable lesions in the expectation of a relatively low mortality. However, some degree of disability—hemiparesis, hemianopia, or dysphasia if the dominant cerebral hemisphere is affected—is still an ever-present and unpredictable risk unless the malformation is well clear of the related cortical areas. Nevertheless, many neurosurgeons prefer to operate if it appears at all feasible to do so, and the indications for excision may therefore be briefly reviewed.

Many of these patients have some form of epilepsy as their sole symptom, and, while it is true that seizures may be modified or abolished at least for a time after operation, surgical treatment is unreliable. Indeed, the resulting brain scar may itself produce fits in some patients who did not have them before operation. Only if the epilepsy is frequent, disabling, and uncontrolled by anticonvulsant drugs does surgery appear to be indicated.

Some believe that the removal of a cerebral angioma is prophylaxis against the insidious development of mental and physical deterioration that these patients sometimes suffer, but firm proof of this is lacking, and any penalty from the operation itself may be unwelcome. Rarely (in only two patients in the series of Henderson and Gomez), the lesion itself gives rise to increased intracranial pressure, for which some kind of decompressive procedure appears mandatory. More often the cause is a sizable haematoma that requires

evacuation, and it is then often possible to remove the angioma at the same time.

Apart from these indications, it seems proper, as Henderson and Gomez suggest, to operate only on those malformations that are likely to be removable without risk of producing serious neurological damage. Estimates of this risk will differ. Thus the proportion of cases submitted to operation, and whether there is resulting neurological damage or not, will depend on the individual surgeon's judgement. But even when the operation has apparently been completely successful statistics cannot ever tell us whether it was necessary in that particular case. If an operation is undertaken, the whole lesion must be removed to ensure prophylaxis, for if any abnormal vessels are left behind the risk of further haemorrhage remains. An ingenious method of treatment remains to be mentioned, that of artificial embolization of the arteriovenous fistulae by means of plastic spheres,⁴ but this may be said to be still in the experimental stage.

Spontaneous intracranial haemorrhage occurring in patients without evidence of cardiovascular disease, and particularly in younger people, always raises anxiety about treatment, so that there is much to be said for knowing early on what is its cause and to be sure that there is not, for example, a small, easily removable angioma situated in a silent area of the brain. Consequently, some workers may consider that cerebral angiography should be undertaken more readily than Henderson and Gomez suggest. However, their important paper indicates that, in the light of present knowledge, conservative treatment may be appropriate for the majority of these patients, and that an angioma need not be removed simply because it is there.

B.M.A. Awards

This week notices appear at the end of the *Supplement* inviting members of the B.M.A. to apply for grants to help their research. Awards of this kind, together with substantial monetary prizes, are a prominent part of the Association's endeavours to "promote the medical and allied sciences," which is the first of its stated objects. If the *B.M.J.* may be forgiven for regarding the publication of this journal and its associated periodicals (15 specialist and two abstracting journals) as pre-eminent in the Association's fulfilment of its primary aim, the numerous scholarships and prizes nevertheless make a large contribution in offering both encouragement and acknowledgement to many doctors keen to advance medicine. In addition, a number are also available to medical students and nurses.

The Chairman of Council, Dr. Ronald Gibson, suggested at a recent meeting of the Committee on Medical Science, Education, and Research (reported at *Supplement* page 92) that maintaining "the interests of the profession," another of the B.M.A.'s declared objects, had somewhat overshadowed its other aims, at least in the public eye. Certainly political conflict is apt to excite attention to an extent unlikely to be rivalled by the uncontentious stimulus to research afforded by grants and prizes. But in a remarkable number of cases a B.M.A. fellowship has been the starting-point for a long and fruitful career in research.

Most of the awards go up to about £300, but now a new whole-time research fellowship of £1,500 is being offered. It is tenable for a year, normally renewable for a second year, and is offered to assist research into any subject relating to the causation, prevention, or treatment of disease.

Papers and Originals

Neurological Sequelae of Prenatal and Perinatal Complications*

H. F. R. PRECHTL,** PH.D.

Brit. med. J., 1967, 4, 763-767

In recent years several attempts have been made to assess the hazards of prenatal and perinatal complications. There is little doubt that obstetric complications carry an increased mortality (De Haas-Posthuma, 1962; Butler and Bonham, 1963). Moreover, where several obstetric complications are present in combination it would be expected, *a priori*, that the risks will be additive. While the exact causes of death in any case may be diverse, one major factor is fatal damage to the central nervous system. Post-mortem examination of the brains of babies who would have died after obstetric complications or unfavourable events during the neonatal period has clearly shown the possibility of these factors producing lesions in the nervous system (Debré *et al.*, 1955; Norman, 1956; Malamud, 1959; Clark and Anderson, 1961; Morf and Bretscher, 1966). Studies in monkeys (Ranck and Windle, 1959; Windle, 1960; Windle *et al.*, 1961) have provided evidence of the harmful consequences of experimentally induced perinatal complications.

While studies of mortality rate have a strict criterion available—death of the foetus within a given period of time—the assessment of damage to the surviving infant is much more difficult. Signs have to be found which indicate the baby's condition, and these signs must have both high interobserver reliability and long-term prognostic value. Apgar's technique has merits but is restricted to the first few minutes after birth and deliberately covers only general aspects of physiological status (Apgar, 1966; Drage and Berendes, 1966). A quite different approach has been used by Graham (1956), Graham *et al.* (1956), and Graham *et al.* (1957), who measured behaviour patterns of babies a few days old.

In my own department a detailed neurological examination has been developed for the assessment of babies (Precht and Beintema, 1964). This examination has good interobserver reliability and high prognostic value (Precht and Dijkstra, 1960; Precht, 1965). In a sample of 102 neonates without neurological signs 86% were found to be neurologically normal at follow-up between two and four years later. Of 150 neonates with abnormal neurological signs, 73% still showed abnormal signs at follow-up during a similar period.¹ Certain constellations of neonatal abnormal signs, which we designated hyperexcitable syndrome, apathetic syndrome, and hemisyndrome respectively, were prognostic of continuing neurological abnormality in 67%, 59%, and 73% of cases respectively, when the latter were examined at 2-4 years (Precht, 1965). Preliminary findings from our follow-up studies at 8 years show a similar picture to that found at 2-4 years. This method of examination may thus be regarded as a highly sensitive indicator of long-term neurological functioning. The identification of

factors which contribute to neurological abnormality in the newborn is therefore a problem of crucial importance.

The aim of the present paper is to examine some interrelationships between obstetric complications and the results of this examination. Our hypothesis is that obstetric complications carry a high risk of neurological damage to the surviving infant. The data on which the present study is based have been collected over a period of 12 years. This paper is restricted to presentation of a number of global findings. Full data will be published elsewhere.

Method

The Sample.—A neurological examination was carried out on 1,515 infants born in the Department of Obstetrics of the Groningen University Hospital. In the Netherlands about 70% of all infants are born at home. The 30% delivered in hospital are therefore primarily cases with a risk of obstetric complications, though a minority go to hospital for social reasons, such as poor housing. From this total the following were eliminated: (1) babies of women who did not regularly attend the outpatient unit of the obstetric department during pregnancy; (2) babies whose birth weight was less than 2,500 g.; (3) babies with gross malformations; (4) babies whose mothers were in a poor nutritional state, suffered from psychiatric disease, epilepsy, diabetes, or heart disease, or whose basal metabolism was low; and (5) babies whose mothers had suffered prolonged sterility. Both categories 4 and 5 occurred rarely in our material. Babies whose condition was poor or dangerous in the first week were not subjected to full neurological examination. The sample remaining after exclusion of the above cases consisted of 1,378 babies.

Neurological Examination.—The standard neurological examination technique has been previously described (Precht and Beintema, 1964). All infants were examined once, two to three hours after a feed. All examinations were carried out between the second and fourteenth days, 91% of them being between the third and tenth days. The babies were picked at random from the obstetric department and were examined without knowledge of the obstetric history.

Data Processing.—The obstetric and neurological data were entered on precoded forms and later transferred to IBM punched cards. Seventy-six items were related to the mother, the course of pregnancy and delivery, and the general aspects of the infant, and 142 items to the neurological examination. All computations were carried out on a general purpose computer (TR4) at the Computer Centre of the University.

Incidence of Obstetric Complications

An obstetric complication may be defined as any factor or group of factors in the prenatal or perinatal environment which

* Mental Health Research Fund Lecture delivered at the Middlesex Hospital Medical School, London, on 22 February 1967.

** Department of Developmental Neurology, University of Groningen, The Netherlands.

¹ The correlation between neonatal findings and the presence or absence of abnormal neurological signs on follow-up gave a value of $\phi=0.583$ ($P<0.0001$).

increases the risk of foetal mortality. These will be symptoms of maternal disease during pregnancy, signs of foetal distress, and mechanical intervention in the delivery. Few of these factors are independent of each other and many are causally related. For example, maternal toxæmia may lead to perinatal foetal distress, which in turn will lead to instrumental extraction.

In order therefore to give a more precise meaning to the rather loosely used term "complication," the following procedure was adopted. For every case 42 variables of the obstetric history were analysed and a count was made of the number of variables which departed from optimal conditions, according to generally accepted criteria. The largest number of such non-optimal conditions was 15, while in 6.2% of our sample all 42 variables were in the optimal condition. Table I shows some of the most frequently occurring non-optimal conditions.

The data were next divided into six subgroups: those with 0, 1-2, 3-4, 5-6, 7-9, and 10 or more non-optimal conditions. The percentage of cases in each subgroup is given for boys and girls separately in Fig. 1.

Fig. 1.—Incidence of non-optimal conditions in boys and girls. Fig. 2.—Percentage of the non-toxaemic (—) and moderate and severe toxæmic cases (+) (N=370) in each subgroup of non-optimal conditions. The difference is significant.

Fig. 3.—Type of delivery and obstetric subgroup. Spontaneous delivery, elective caesarean sections C.S. I (N=33), non-elective C.S. II (N=48), middle forceps (N=85), and low forceps (N=133) are presented separately.

There were no statistically significant sex differences with respect to occurrence of non-optimal obstetric conditions. In the subsequent analysis the data for boys and girls are combined.

TABLE I

Condition	No.	%
Maternal age above 30 years	342	25.0
Moderate toxæmia	250	18.1
Severe toxæmia	108	8.5
Other than vertex presentations	235	17.2
Non-spontaneous delivery	427	31.0
Caesarean sections	81	5.9
Middle forceps	75	5.4
Low forceps	133	9.7
Prolonged labour ≥24 hours	170	12.3
Second stage longer than two hours	96	7.0
Tight cord around the neck	101	7.3
Foetal bradycardia <100/min.	188	13.6
Post-partum apnoea >1 min.	224	16.3

Interrelationships between Non-optimal Obstetric Conditions

It is of interest to examine which conditions occur in combination with others and which do not. This summary is confined to three examples only, illustrating complications of pregnancy, delivery, and foetal state respectively.

Toxaemia.—If all cases with moderate or severe toxæmia (characterized by blood pressure $\geq 140/95$ and by albuminuria and oedema respectively) are compared against the rest with respect to the distribution of non-optimal conditions it will be seen that there is a marked tendency for the toxæmia cases to occur in association with a large number of other non-optimal conditions (Fig. 2).

Delivery.—A similar picture emerges, as might be expected, for instrumental as compared with spontaneous deliveries (Fig. 3).

Foetal Heart Rate and Apnoea.—Signs of foetal distress, such as tachycardia or bradycardia during the second stage (Fig. 4) and post-partum apnoea longer than one minute (Fig. 5), behave similarly to the complications above.

Non-optimal Obstetric Conditions and Neurological Symptoms

Most of the items of the neurological examination are assessed on an ordinal scale with three or four points. For instance, the palmar grasp reflex is recorded as being absent (—), being weak or just discernible (+), giving a good sustained response for 10 seconds (++) , or giving an exaggerated forceful grasp (+++). The rooting response is recorded as being absent (—), showing only a weak turn toward the stimulated side (+), giving a full turn and a grasp with the lips (++), and consisting of a very vigorous turn with grasping (+++). The intensity of the Moro reflex is recorded as low, middle, or high. In the case of the palmar grasp reflex and rooting response the ++ category may be regarded as the optimal response, whereas for the Moro reflex the optimal response would be that of intermediate intensity and threshold.

If we assume that for each item of the neurological examination there is an optimal response we may examine the frequency with which cases with varying numbers of obstetric complications fall into the optimal and non-optimal categories.

For the purpose of this analysis the data were divided on the

basis of the obstetric complications into three subgroups: (1) a "low risk" group (N=264; 19.2%) with no or only one non-optimal condition; (2) a "middle risk" group (N=943; 68.4%) with two to six non-optimal conditions; and (3) a "high risk" group (N=171; 12.4%) with seven or more non-optimal conditions. The word "risk" is used to denote a raised probability of mortality during the delivery and the first two weeks of life. It involves no assumptions about the possible outcome of the neurological examination.

FIG. 4.—Foetal heart rate and non-optimal conditions. The tachycardia group with a heart rate >160/min. (N=59) and the two groups of bradycardia 100-80/min. (N=101) and <80/min. (N=89) are all significantly different from the group with normal heart rate (160-100). FIG. 5.—Onset of respiration and incidence of non-optimal conditions. The longer the apnoea the more other non-optimal conditions are present. The difference is highly significant at 1-3 min. (N=187) and >3 min. (N=37).

FIG. 6.—Distributions of response intensities of the palmar grasp reflex in the low and high risk groups. The difference is significant ($\chi^2=60.9$; $P<0.001$). FIG. 7.—Distributions of response intensities of the rooting response in the low and high risk group. The difference is significant ($\chi^2=22.2$; $P=0.001$).

For illustration the distributions of response intensities of the palmar grasp reflex and the rooting response are shown for the low and high risk groups (Figs. 6 and 7).

Fifty-eight neurological items were selected which, as above, could be assigned a position on a four-point ordinal scale. Contingency tables were constructed showing the frequency with which patients from the three risk groups fell into different positions on each scale. In 42 of the tests the differences between expected and observed frequencies as measured by χ^2 tests were significant at least at the 1% level of confidence. The low risk group predominantly showed those responses described as "optimal," whereas the high risk group showed relatively few optimal responses. In all 42 items the middle-risk group was intermediate between the other two with respect to the number of optimal responses. In other words, there is a highly significant association between the number of non-optimal obstetric conditions and neurological abnormalities in the newborn.

The relation between non-optimal obstetric conditions and neurological abnormality is seen even more clearly if we carry out the following transformation. For each ordinal item of the neurological examination a score of "1" was given if the baby's response was in the optimal category. It was thus possible to obtain a "neurological score"—the number of items of the neurological examination in which the baby gave an optimal response. For all babies on whom the full neurological examination was carried out (N=1,378) the neurological scores were plotted against the corresponding number of non-optimal conditions. It was found that the mean neurological score decreased as the number of obstetric complications increased.

The neurological scores were next separated into three main groups, taking the following cut-off points: scores equal to 47 or less, scores 48 to 52, and scores 53 to 58. The babies in each of these three groups were then allocated, on the basis of

TABLE II

Neurological Scores	Risk Group			Totals
	Low	Middle	High	
≤47	73 (101.7)	375 (363.4)	83 (65.9)	531
48-52	84 (87.9)	316 (314.1)	59 (57)	459
53-58	107 (74.3)	252 (265.5)	29 (48.1)	388
	264	943	171	1,378

Figures in parentheses are expected frequencies.

their mother's obstetric score, to the high, middle, and low risk groups. The relation between the neurological and obstetric findings is shown in Table II. There was a very highly significant difference between the observed and expected frequencies with which the three neurological subgroups were represented in the three risk groups ($\chi^2=38.5$, d.f.=4, $P<0.001$). It is clear, therefore, that there is a high association between obstetric complications as measured by the obstetric scores—and the occurrence of neonatal neurological abnormalities.

Obstetric Risks and Neurological Syndromes

If a group of symptoms occur repeatedly in combination they may be said to constitute a syndrome. We have previously described a combination of low intensity of general motor activity and of sucking, rooting, hand- and foot-grasping, head-lifting in prone position, recoil of forearms, and the labyrinthine reflex—the *apathy syndrome* (Prechtl and Dijkstra, 1960). Similarly, babies showing lowered resistance to passive movements of the neck, trunk, shoulder, elbow, hand, hip, and knee and ankle joints have been described as hypo-

tonic. Significantly more babies showing the apathy syndrome and hypotonia were found in the high risk group than in either the middle or the low risk group. Babies with asymmetries of posture, tendon reflexes, and skin reflexes* (which we have previously described as the *hemisindrome*) were equally distributed among the three risk groups. Interestingly, however, babies with the hemisindrome and those with facial palsies had a significantly raised incidence of occurrence after forceps delivery and version-extraction. Babies who are what we have called *hyperexcitable* were significantly overrepresented in the middle risk group. Hyperexcitability occurred significantly more among the boys.

Neurological Scores and Classical Neurological Signs

I have so far argued that there is a high positive correlation between non-optimal obstetric conditions and neurological abnormality as measured by our standardized procedure. Because neonatal abnormalities with this technique are predictive of continuing abnormality and future behavioural disturbance (Prechtl, 1965) we believe it is essential that full neurological examination is carried out on all babies who are obstetrically at higher risks. It might be argued, however, that since the full examination is a time-consuming and expensive procedure it is sufficient to record the presence of obvious neurological signs which any well-trained obstetrician or paediatrician could not fail to see. In fact, 25 of our babies showed one or more "obvious" neurological signs: facial palsies; bulging fontanelles; deviation of eye position; absence of sucking, Moro, or palmar grasp reflexes; severe floppiness; or marked asymmetry.

It is of interest to examine the distribution of the neurological scores of these babies relative to that of the remainder. No baby with an obvious neurologically abnormal condition ever obtains fewer than four non-optimal subtest items—that is, the baby is never misclassified as normal by our examination. On the other hand, a very large number of babies with no classical neurological signs obtain the same neurological scores as those with such classical signs. It is clear, therefore, that examination merely for gross pathological signs will result in the omission of a considerable amount of neurological abnormality which is prognostically ominous. Thus the presence of "classical neurological signs" is not exclusive evidence of neurological abnormality. Moreover, we have shown that neurological abnormality, as measured by the full standardized procedure, increases in relation to the number of non optimal obstetric conditions. It therefore follows that the urgency for full neurological examination of the newborn increases also as a function of the number of non-optimal obstetric conditions present.

Discussion

The identification of what constitute obstetric hazards remains still an urgent clinical problem. An approach to this question through studies of mortality rate has great merits, but the answers must remain incomplete, since the majority of infants survive obstetric complications. Among these babies, however, may be many who suffer major or minor impairment of brain function. The early recognition of nervous dysfunction is of great importance both with respect to the possibility of early treatment and in relation to handling difficulties arising during the development of the mother-infant relationship. Many studies seem to indicate that, besides handicaps such as cerebral palsy due to prenatal and perinatal brain damage, minor brain dysfunctions, undramatic from the clinical neurological point of view, may lead to severe problems in the life of children and their parents. Though well-controlled studies are still scarce the available data are alarming.

In the context of these aspects the need for early indicators of risks is evident. The attempt to design risk registers which would select those babies from the population who are at special risk of brain damage is a major task. If only for the purpose of practical management, criteria are needed which do not select for special attention half or even more of all newborn babies. In the light of our study, one possible approach is through the obstetric score. It will be remembered that obstetric scores were highly correlated with neurological findings which were themselves predictive of continuing abnormality. In practice this would mean filling in a check-list of non-optimal conditions that results in a risk score. This is obviously a more reliable strategy than to look only for the presence of particular dangerous obstetric conditions in the baby's history.

As a further result of our study new criteria are suggested for the interpretation of the quantitative results of our neurological test items. Though it was possible previously to indicate the optimal intensity of responses, it was still questionable, for many responses, at which points of the scale one should speak of an abnormal response, a fact we have indicated in our manual for the neurological examination of the full-term newborn infant (Prechtl and Beintema, 1964). Differences found between the neurological item scores of the obstetrically high risk group and those of the low risk group are very suggestive of a more valid demarcation of neurological abnormality. For example, with respect to the rooting response, the differences between the two risk groups are apparent in the scores — and +, but the incidence of +++ is no higher in the high risk group than in the low risk group. This offers a possible operational definition of "abnormal" as being the — and + responses only, in contrast to the normal responses ++ and +++. In the case of the palmar grasp response, on the other hand, the +++ response would still be regarded as abnormal.

This new information is valid for many test items of the neurological examination. There remain certain neurological signs which are undoubtedly abnormal, such as the absence of sucking or of the Moro response, persistent deviation of the eyes. Our study has shown, however, that application of these generally accepted criteria of abnormality alone would leave many neurologically abnormal babies unrecognized. The French technique as advocated by Dargassies (1962) uses only such qualitative signs. The quantitative assessment of neurological signs is not, however, a mere academic refinement of neurological examinations, but a clinical necessity.

Summary

A group of 1,378 full-term newborn infants born in the Obstetric Department of the University of Groningen were subjected to a standardized quantitative neurological examination in their first 10 days of life. Data on pregnancy, delivery, and condition of the infant at birth were available.

Since previous correlation analysis of neurological results with obstetric complications failed to give instructive results a new approach was carried out. Forty-two variables of the prenatal and perinatal history were analysed and counted if they deviated from optimal condition, giving an obstetric risk score for each baby. The distributions of response intensities of many neurological items were shown to be different in the low, middle, and high risk groups. This held true also for some syndromes. The number of optimal neurological responses was negatively correlated with the number of non-optimal obstetric conditions.

It was shown that non-optimal conditions tended to occur in association with each other. The more a condition deviated from the norm, the greater the number of other non-optimal conditions associated with it. A simple count of the number of such non-optimal conditions present offers promise as a means of identifying those babies at risk of neurological damage.

It is suggested that the criteria for assessing what is an abnormal neurological response may be refined by reference to the responses of our low and high risk groups.

My thanks are due to Professor L. A. Joosse and Professor B. S. ten Berge, of the Department of Obstetrics, University of Groningen, for their interest and co-operation over the many years of this study. I am also indebted to my co-workers, Drs. J. D. Beintema, J. Dijkstra, A. v.d. Gaag, W. Lawant, and B. C. L. Touwen, for their part in collecting the data. Without the great assistance of Dr. D. Smits, director of the Computer Centre of the university, and Dr. R. Wippler and Mrs. J. H. van Dijk-v.d. Horst the data-processing would have been impossible. I want to express my warm appreciation for the help of Dr. S. J. Hutt in the preparation of the manuscript. This study was supported by a grant from the Association for the Aid of Crippled Children, New York.

Concentration of Methoxyflurane for Obstetric Analgesia by Self-administered Intermittent Inhalation

VALERIE MAJOR,*† F.F.A.R.C.S.; MICHAEL ROSEN,* F.F.A.R.C.S.
 WILLIAM W. MUSHIN,* F.R.C.S., F.F.A.R.C.S.

Brit. med. J., 1967, **4**, 767-770

Methoxyflurane has been shown to possess advantages over trichloroethylene as an obstetric analgesic (Major, Rosen, and Mushin, 1966). In that initial study we varied the concentration of both vapours continuously, with the aim of giving each patient the best possible analgesia without undesirable side-effects. The design of the trial made it possible (by analysing the continuous recordings of the inhaled concentrations of methoxyflurane) to deduce that for intermittent use a single fixed concentration of the drug would prove adequate and that this would be 0.35%. The present trial tests the validity of these predictions.

Method

Two concentrations of methoxyflurane in air (0.35% and 0.25%) were compared. These were chosen because observations in our first trial indicated that patients tended to become unacceptably drowsy at concentrations higher than 0.35%. This decision has been confirmed by observations of some patients in this trial who were studied at a higher concentration (0.45%).

Methoxyflurane was given from identical Penlon P.D.V. vaporizers, as these were the most accurate "draw-over" vaporizers available to us for this drug. Each was modified so that only one predetermined concentration could be given. The vaporizers were calibrated by us with a katharometer, using a Beaver ventilator as a dummy patient, and the concentrations were checked frequently throughout the trial. Before being used by a patient each vaporizer was flushed with oxygen for at least three minutes to clear the "dead" space.

* Department of Anaesthetics, Welsh National School of Medicine, Cardiff.

† Abbott Research Fellow.

The day on which each concentration was used was previously randomized. Though an anaesthetist was present as an assessor throughout the inhalation, the conduct of analgesia was left to the midwife, so that the conditions were as near "normal" as possible. Inhalation was therefore started at the midwife's discretion, usually towards the end of the first stage of labour. A record was kept of the dose and time of administration of other drugs given during labour; no direction or restriction was made regarding their use. Assessments were made separately by an anaesthetist, by the midwife, and by the mother.

The same anaesthetist was present for all cases and made continuous assessments. For the full details of the method of assessment readers are referred to our previous paper (Major *et al.*, 1966). In brief, assessments are made of the mother's response to contractions, her level of consciousness, and any restlessness between contractions. The anaesthetist's observations are plotted to show the proportion of time during the whole period of observation for which each of the three factors is deemed "satisfactory." The periods for which all factors are satisfactory are calculated and expressed as a percentage of the total duration of inhalation.

As in the previous trial, the midwife, for whom the trial was blind, gave her assessment just after delivery with respect to the degree of analgesia, the drowsiness of the patient, and the restlessness of the patient. The mother was questioned twice—15 minutes after delivery and then 36 to 48 hours later. The questions at 15 minutes were slightly modified in this trial. She was asked: "Do you consider that what you had to breathe helped you?" "Do you feel drowsy?" "Did you drift off at all?" and "Could you do what we asked?" At the second visit other questions were asked regarding nausea, vomiting, memory, and smell.

Measurements of ventilation were made in some mothers by means of a Wright respirometer and a stop-watch. The baby was assessed by the Apgar score at one minute, and by noting the time to the onset of regular respiration.

Results

Forty-three patients were given inhalational analgesia. Twenty-three had 0.35% methoxyflurane (11 primigravidae, 12 multigravidae—19 spontaneous vertex deliveries) and 20 had 0.25% methoxyflurane (10 primigravidae, 10 multigravidae—18 spontaneous vertex deliveries).

Duration of Inhalation

The shortest period of inhalation was 16 minutes and the longest 6 hours 30 minutes. The mean duration for 0.35% methoxyflurane (0.35 group) was 1 hour 30 minutes, and for 0.25% methoxyflurane (0.25 group) 1 hour 26 minutes ($P > 0.70$). The groups appear similar in this respect.

Observations by Anaesthetist

All Factors Satisfactory (Table I).—The percentage of time of inhalation for all factors satisfactory was determined for each patient. The mean for each group was calculated. The 0.35 group was satisfactory for significantly longer (72.7%) than the 0.25 group (55.5%).

TABLE I.—Percentage of Duration of Inhalation Regarded as Satisfactory

Factor Studied	Mean Percentage of Time Satisfactory		Significance (t test)
	0.35% Methoxyflurane (23 patients)	0.25% Methoxyflurane (20 patients)	
All factors satisfactory	72.7	55.5	$P < 0.05$
Reaction to contraction satisfactory	72.8	55.5	$P < 0.05$
Level of consciousness satisfactory	100	100	
Restlessness satisfactory	98.9	94.6	$P < 0.10$

Reaction to Contraction (Table I).—The 0.35 group was significantly better in this respect (72.8%) than the 0.25 group (55.5%).

Level of Consciousness (Table I).—All the patients were satisfactory.

Restlessness between Contractions (Table I).—Only six mothers showed any restlessness—two received 0.35% and four received 0.25% methoxyflurane. The 0.35 group was satisfactory for slightly longer than the 0.25 group.

Effect of Duration of Inhalation on All Factors Satisfactory (Table II).—The effect of the duration of inhalation was studied by dividing each labour into consecutive half-hour periods starting five minutes after the beginning of inhalation. The mean time for the 0.35 group was higher for each half-hour period, and the difference between the two groups is significant in the first half-hour.

Effect of Progress of Labour on All Factors Satisfactory (Table II).—The effect that the progress of labour had on

all factors satisfactory was examined for the half-hour period immediately preceding delivery: the mean time for the 0.35 group was significantly higher.

TABLE II.—Effects of Duration of Inhalation and Progress of Labour on All Factors Satisfactory

Group	Mean Percentage of Time All Factors Satisfactory			
	Half-hour Period of Inhalation			Half-hour Preceding Delivery
	1st	2nd	3rd	
0.35	80.3	76.5	71.4	79.5
0.25	59.4	55.3	46.6	53.2
Significance (t test)	$P < 0.05$	$P < 0.20$	$P > 0.20$	$P < 0.02$

Effect of Pethidine on All Factors Satisfactory (Table III).—Nearly the same proportion of patients in each group received pethidine during the four hours immediately preceding the start of inhalation (13 out of 23 patients in the 0.35 group and 12 out of 20 in the 0.25 group). The difference in the assessment between the two groups does not appear to be due to the administration of pethidine.

TABLE III.—Effect of Pethidine on All Factors Satisfactory

Group	Mean Percentage of Time All Factors Satisfactory		Significance (t test)
	Pethidine during 4 hours Preceding Inhalation	No Pethidine during 4 hours Preceding Inhalation	
0.35	74.1	71.0	$P > 0.70$
0.25	54.1	58.0	$P > 0.70$

Opinion of Midwife

The midwives thought the analgesia "complete" in 31% of the mothers in the 0.35 group and in 5% of the mothers in the 0.25 group. This difference is significant (Table IV).

TABLE IV.—Midwives' Opinion of Analgesia

Group	Complete	Considerable	Slight	None	Significance	
					Complete v. All Other Replies	Complete and Considerable v. All Other Replies
0.35	7 (31%)	15 (65%)	1 (4%)	0 (0%)	} $P = 0.037$	} $P < 0.20$
0.25	1 (5%)	15 (75%)	4 (20%)	0 (0%)		

One patient (4%) of the 0.35 group was graded as restless, and four (20%) of the 0.25 group. The restless mother in the 0.35 group was graded as having "considerable" pain relief, whereas the four in the 0.25 group were also graded as having "slight" analgesia.

No mother in either group was thought by the midwives to be "too drowsy."

Opinion of Mother

Assessment of Pain Relief at 15 Minutes after Delivery (Table V).—Pain relief was thought to be "complete" in 43% of the 0.35 group and in 15% of the 0.25 group. This

TABLE V.—Mothers' Opinion of Pain Relief

Mothers' Assessment after Delivery	Group	Complete	Considerable	Slight	None	Significance	
						Complete v. All Other Replies	Complete and Considerable v. All Other Replies
At 15 min.	0.35	10 (43%)	13 (57%)	0 (0%)	0 (0%)	} $P = 0.044$	} $P = 0.21$
	0.25	3 (15%)	15 (75%)	1 (5%)	1 (5%)		
At 36-48 hours	0.35	8 (35%)	15 (65%)	0 (0%)	0 (0%)	} $P = 0.21$	} $P = 0.039$
	0.25	3 (15%)	13 (65%)	3 (15%)	1 (5%)		

difference is significant. No mother having 0.35% methoxyflurane gave a grading lower than "considerable." In the 0.25 group the inhalation was stopped in one case after an hour because the mother complained of getting no pain relief.

Assessment of Pain Relief at 36–48 Hours after Delivery (Table V).—Four mothers of the 0.35 group changed their previous opinion—three from "complete" to "considerable" and one from "considerable" to "complete" pain relief. In the 0.25 group two mothers changed from "considerable" to "slight" pain relief. In this later assessment those replying "complete" or "considerable" are significantly more in the 0.35 group.

One patient in each group had to be excluded from some of the more detailed questions owing to language difficulties.

Other Questions at 15 Minutes after Delivery.—Drowsiness: Nine out of 22 (43%) mothers in the 0.35 group and 7 out of 19 (37%) in the 0.25 group said they felt drowsy. **Sleep:** Only one patient (0.35 group) felt herself "drifting off." **Ability to Obey Commands:** All patients felt able to do all that was asked of them during labour.

Other Questions at 36–48 Hours after Delivery.—Memory of Labour and Delivery (Table VI): There was little difference between the two concentrations with regard to memory for labour and delivery. **Smell:** 13 (57%) of the mothers in the 0.35 group and 12 (60%) in the 0.25 group noticed the smell; only one (0.25 group) thought the smell unpleasant. **Nausea and Vomiting:** In the 0.35 group three mothers (13%) felt nauseated during delivery and another three in the next 24 hours; one of them (4%) vomited. Altogether six (26%) in the 0.35 group were affected. Only one patient in the 0.25 group felt sick, and that was during delivery; none vomited. The difference between the two groups is nearly significant ($P=0.07$).

TABLE VI.—Mothers' Memory of Labour and Delivery

	Group	Mothers' Memory		
		Clear	Hazy	None
Labour	0.35	17 (77%)	5 (23%)	0 (0%)
	0.25	13 (68%)	6 (32%)	0 (0%)
Delivery	0.35	19 (86%)	2 (9%)	1 (5%)
	0.25*	16 (88%)	2 (12%)	0 (0%)

* One patient excluded (caesarean section).

Other Criteria

Condition of Babies.—Of the babies in the 0.35 group 92% had an Apgar score at one minute of 8 or over; and 89% in the 0.25 group. The onset to regular respiration was within one minute in 84% of the 0.35 group and 88% of the 0.25 group. The differences are not significant. No baby required artificial ventilation.

Blood Loss.—The mean blood loss, assessed by the midwife, was 5 oz. (142 ml.) in the 0.35 group and 8 oz. (227 ml.) in the 0.25 group. There was one postpartum haemorrhage of 40 oz. (1,134 ml.) in the 0.25 group after a vacuum extraction.

Inhaled Concentrations. Vaporizer.—We intended the mothers to inhale a constant concentration of methoxyflurane. However, the wide variations in ventilation which occur during

TABLE VII.—Concentration of Methoxyflurane Delivered at Various Minute Volume Ventilations

Ventilation		Concentrations Delivered by Vaporizer			
Minute Ventilation (l./min.)	Tidal Volume (ml.)	0.25% Setting		0.35% Setting	
		3 min.	30 min.	3 min.	30 min.
5	250			0.35%	0.35%
10	500	0.25%	0.25%	0.35%	0.35%
15	750	0.25%	0.25%	0.33%	0.33%
20	750	0.24%	0.24%	0.33%	0.33%
25	930			0.31%	0.31%
30	1,100	0.21%	0.21%	0.29%	0.29%

labour make this technically difficult to attain with any "draw-over" vaporizer. We chose for the trial the vaporizer which gave us the most constant concentrations under simulated clinical conditions in the laboratory. The variations in concentration with these vaporizers at different minute ventilations are shown in Table VII. The uptake of methoxyflurane by the rubber hose was also investigated. The results show that a standard length of rubber breathing-tube has only a negligible effect on the inhaled concentration (S. C. Khataniar, personal communication, 1967).

Inhaled Concentrations. Ventilation.—Serial measurements of ventilation were made during contractions in 12 out of 23 in the 0.35 group and in 10 out of 20 in the 0.25 group. The ventilation during each contraction in the half-hour immediately preceding full dilatation was selected for study, since minute volume is greatest at the end of the first stage of labour (Reid, 1966). The ventilatory volumes in Table VIII were calculated from measurements made in the first 30 seconds of the contraction, since the majority of our patients stopped inhaling within 50 seconds of the onset of the contraction. None inhaled for less than 30 seconds. The mean and standard deviation for each patient and each group are shown in Table VIII. The distribution of all these measurements of ventilation is shown in Table IX.

TABLE VIII.—Mean Ventilation Per Minute Measured for 30 Seconds of Each Contraction in the Half-hour Preceding Full Dilatation

Patients' Code	Methoxyflurane 0.35%		Patients' Code	Methoxyflurane 0.25%

χ^2 test, $P < 0.01$.

The difference seen between the two groups indicated that higher ventilations accompany the less satisfactory pain relief of 0.25%. This difference is significant. This increase in ventilation is probably due to a mixture of a heightened respiratory response to pain and an attempt on the part of the patient to compensate for inadequate analgesia.

Rejection of 0.45% Methoxyflurane

Eight patients were given 0.45% methoxyflurane (mean duration of inhalation 1 hour 10 minutes; range 30 minutes to 2 hours). Five of the eight mothers (who had all received pethidine) were assessed as "very drowsy" by the anaesthetist. The mean percentage of time of inhalation during which the level of consciousness was deemed unsatisfactory in these eight patients was 17. We could not accept this high liability to drowsiness. Our opinion was confirmed by the midwives, who scored two of these patients as "too drowsy." Pain relief as

assessed by the mothers was no better with this concentration than with 0.35%. It became clear to us that a concentration of 0.45% methoxyflurane introduced no obvious benefit and was too strong for general use unless restrictions were to be placed on the duration of inhalation and perhaps on the use of pethidine.

Discussion

The mothers', the midwives', and the anaesthetist's assessments all demonstrated that 0.35% methoxyflurane is a better concentration than 0.25%.

In our previous trial (Major *et al.*, 1966) our aim was to vary the inhaled concentration for each mother until either there was no reaction to a contraction or she became too drowsy or restless. Therefore on theoretical grounds, because the inhaled concentration was carefully and continuously adapted for the needs of each patient (and must have been optimal), no improvement can be expected on the score recorded then for reaction to contraction. On the other hand, since in our first trial the methoxyflurane had to be "pushed" so as to assay its full potential value, there was inevitably a small incidence of side-effects. This must have reduced somewhat the best possible score for "all factors satisfactory." Our present trial of 0.35% methoxyflurane has equalled the original trial with regard to the score for reaction to contractions (72.8 and 71.8%), and has exceeded it for all factors satisfactory (72.7 and 60.3%). Since the percentage of time "satisfactory" for reaction to contractions with 0.35% methoxyflurane is the same as that achieved in our previous trial, and both a lower and a higher concentration proved less satisfactory, 0.35% must clearly be the optimum concentration. The mothers' and midwives' opinions of the 0.35% support the anaesthetist's assessments. In fact, they show a slight improvement on the results in the original trial.

Our conclusion about the optimum concentration is based on the administration of fixed known inhaled concentrations. We realized, however, that even the best temperature-compensated "draw-over" vaporizer would not give an absolutely fixed concentration, owing to the high ventilation which commonly occurs during contractions. However, the effects of any ventilatory changes are small with the vaporizer used in this trial. The maximum ventilation measured in our patients was about 30 l./min.—that is, a change of about 100% from the mean ventilation. At this the inhaled concentration fell by only 17%—from 0.35 to 0.29% (Table VII). Even at the extreme of ventilation measured in our patients this slight fall in inhaled concentration has a relatively small effect on the alveolar concentration, because of the large increase in the coincidental and causative minute volume (Mushin and Galloon, 1960).

Our recommended concentration of 0.35% methoxyflurane is less than that reported by other workers. Bodley *et al.* (1966), using a reputed 0.5% methoxyflurane from a Cyprane A.E. vaporizer, found that 82.2% of mothers thought the pain relief complete or adequate. However, 12.7% were unco-operative as judged by the anaesthetist-observer. Johnstone (1963), using an uncompensated vaporizer with "0.5%," found the analgesia inadequate, but 4 out of 25 (16%) of his patients were too sleepy to co-operate in the second stage. Canadian and American workers (Romagnoli and Korman, 1962; Savel *et al.*, 1967) also used an uncompensated inhaler—the Cyprane—at the setting recommended by Messrs. Abbott in their literature. Holl and Shnider (1967) have shown that the Cyprane vaporizer gives an initial concentration of 1%, falling in a few minutes to between 0.4 and 0.5%, and that general anaesthesia may develop. It is important to stress that our own results were achieved with a virtually constant inhaled concentration from a vaporizer well compensated for temperature and over a wide range of ventilation. It is clear from our

trial that a change in inhaled concentration of 0.1%, which may appear small, does in fact make a great difference to the results.

Our ultimate aim is to determine whether methoxyflurane is suitable for administration by unsupervised midwives. We therefore observed strict criteria in seeking for a concentration which would not only give a degree of analgesia at least as good as that commonly attained with trichloroethylene, but in addition would ensure full co-operation of the mother during delivery—not always a feature of existing methods. The value of methoxyflurane depends on whether this is possible: the results of our studies indicate that it is. Furthermore, the quality of the pain relief appears to be quite different from that seen with either trichloroethylene or nitrous oxide. The mother lies quietly, looking well sedated but quite able to co-operate. Many mothers comment spontaneously that they feel detached from the process of labour and that any pain seems remote.

The only side-effects of note were nausea and vomiting, well known to occur in association with labour. The incidence of these in our trial (0.35 group), bearing in mind that our inquiries extended for 24 hours after delivery, was comparable to that observed in connexion not only with methoxyflurane but with other analgesics as well (Johnstone, 1963; McAneny and Doughty, 1963; Bodley *et al.*, 1966; Ransom, 1966).

Our initial experimental study was concerned with developing a screening method to ascertain the value of methoxyflurane as a self-administered obstetric analgesic. The method has clearly proved able to produce reliable predictions about the intermittent use of methoxyflurane and of the concentration required. In addition, it has done so with remarkable economy of patients. Now that we have established that methoxyflurane has attractive qualities as an obstetric analgesic we believe that it should be given a wide field trial. This we propose to do.

Summary

The present investigation has confirmed the value of our previously published method for screening obstetric analgesics from which we predicted that 0.35% methoxyflurane would prove suitable for intermittent self-administration during labour.

Fixed inhaled concentrations of 0.35% and 0.25% methoxyflurane in air, from carefully calibrated thermo-compensated vaporizers, were compared. The results were assessed by an anaesthetist, by the mother, and by the midwife. All these assessments indicate that 0.35% is significantly better than 0.25% methoxyflurane. A higher concentration introduces an unacceptable degree of drowsiness. A field trial is now in progress.

We wish to thank our obstetric colleagues and the midwives at the Maternity Unit, St. David's Hospital, Cardiff, for their enthusiastic help and collaboration during this trial. We would also like to acknowledge the useful comments and criticisms of W. W. Mapleson, Ph.D., and of many other colleagues. This work was partially supported by a grant from Abbott Laboratories Ltd. The vaporizers were kindly presented by Longworth Scientific Ltd. (Penlon).

Improving the Acceptability of Oral Continuous Progestogens in Microdosage for Fertility Control

JUAN ZAÑARTU,* M.D.

Brit. med. J., 1967, **4**, 771-772

The use of continuous microdoses of progestogens is a new concept in fertility control, and a major improvement of oral contraception. Introduced by Martinez-Manautou, Cortez-Gallegos, and Rudel in 1964, it has aroused an increasing interest in the medical profession because of its simplicity, excellent tolerance, and effectiveness. These advantages explain its present popularity (Martinez-Manautou *et al.*, 1966a, 1966b, 1967a, 1967b, 1967c; Martinez-Manautou and Rudel, 1967).

Our own experience with oral continuous chlormadinone acetate 500 µg. in 390 young fertile women observed during 3,400 months confirms the qualities recently reported by Martinez-Manautou *et al.* (1967a) in a much larger group of women followed during 13,202 cycles. However, we have had a slightly higher incidence of accidental pregnancies due to therapy failure (3.3 per 100 treated women) (Zañartu *et al.*, 1967a).

The method is particularly useful in women intolerant to conventional oral oestrogen/progestogen contraceptives. It requires a much lower dosage to inhibit fertility, without necessarily interfering with ovulation—another advantage particularly for young women wishing to plan their families (Rudel and Martinez-Manautou, 1966).

However, according to recent reports irregular uterine bleeding and menstrual cycles are significant side-effects in more than 35% of the users. In our observations, unfortunately, the incidence of irregular uterine bleeding, prolonged menstrual cycles, and amenorrhoea is high enough to be annoying. Indeed, it is a factor which causes women to discontinue therapy (Zañartu *et al.*, 1967a).

This paper reports a simple improvement in an attempt to correct such a side-effect.

Material and Methods

Fifty young fertile women who had previously taken oral contraceptives were selected from a large group. They used conventional "combined" or "sequential" oestrogens/progestogens, but because of poor tolerance this method was discontinued, and oral chlormadinone acetate (0.5 mg. daily) was given instead. While they were under oestrogen/progestogen therapy their menses were regular and acceptable. The subjects were from an educated and high socio-economic group; they had completed high school and many were professional women enjoying a comfortable life.

Once the new therapy was started menstrual records were carefully kept. Patients were seen at regular intervals of three to four months, and a complete clinical and gynaecological examination was performed at each control.

Clinical and laboratory findings on subjects under continuous chlormadinone therapy have been reported (Zañartu *et al.*, 1967a). This particular group of women were included in our study because while on oral continuous chlormadinone they presented irregular uterine bleeding (mainly hypermenorrhoea, spotting, and/or intermenstrual bleeding), prolonged cycles

(over 45 to 60 days), or amenorrhoea. The condition interfered with the acceptability of the method. In fact the fear of being pregnant arose when menses were delayed or because of amenorrhoea. This increased the incidence of office calls and consultations. Evidently they were annoyed by the disturbance in spite of the good tolerance of the method.

To correct uterine bleeding and regulate cycles, oral "accessory" oestrogens were given for five to seven days in each calendar month, or from the 21st to the 25th or the 19th to the 25th day of the menstrual cycle. In other words, one extra tablet of conjugated oestrogens (Premarin 2.5 to 5 mg. daily) was given during these days because of the good tolerance to it. However, 0.05 mg. of ethinyloestradiol was occasionally given in the same fashion when well tolerated.

The possibility that accessory oestrogens could reverse the cervical mucous changes induced by the progestogen, and nullify its contraceptive effect, was studied by post-coital Huhner-Sims tests performed at the expected ovulation time of the cycle.

Results

The effect of "accessory" oestrogen therapy in regulating menstrual cycles and making uterine bleeding more comparable with normal menses was evident, and it was satisfactory to all treated subjects. This effect was achieved without interference with the antifertility action of oral continuous contraceptive therapy with microdoses of chlormadinone acetate. In fact not a single accidental pregnancy occurred in this group during 650 months of observation.

The accessory therapy was added during five or seven days in each calendar month while the subject received one 0.5-mg. tablet of chlormadinone acetate daily. The effect of this additional therapy on uterine bleeding and cycles is summarized in the Table. It will be seen that the average duration of uterine bleeding and menstrual cycles is quite acceptable.

"Accessory" Oestrogen Therapy in 50 Women

No. of Cases	Oestrogen Therapy		Uterine Bleeding (Average) Duration Days	Menstrual Cycles (Average Duration) Days
	Daily Dose	No. Days*		
35	C.O. 2.5 mg.	5 or 7	4.7 (3 to 8)	29.7 (26 to 33)
12	C.O. 5.0 mg.	5	3.9 (3 to 7)	28.5 (27 to 32)
3	E.O. 0.05 mg.	5 or 7	3.5 (2 to 6)	26.9 (26 to 31)

C.O. = Conjugated oestrogens (Premarin).

E.O. = Ethinyloestradiol.

* Of each calendar month, or from 21st to 25th day or 19th to 25th day of the cycle.

During the study 45 tests were performed 4 to 12 hours after coitus at about the expected ovulation time of the corrected cycle. In 35 tests the anti-oestrogenic effect of chlormadinone was evident: the mucus was thick, tenacious, with low spinnbarkeit, was loaded with leucocytes and cells, and did not crystallize. However, this effect was minimal in 10 tests. The physical characteristics of mucus were similar to those observed at about the 14th or 15th day of normal non-treated

* Department of Fertility, University Maternity Hospital, University of Chile Medical School, Santiago, Chile.

ovulatory cycles with good sperm tolerance. The tests were performed from 10 to 18 days after the last additional oestrogen tablet was taken.

Discussion

The incidence of uterine bleeding and menstrual cycle modifications in women receiving oral continuous chlormadinone acetate in microdoses is significant. In our experience 153 (39.2%) out of 390 women presented some alterations in uterine bleeding while using this contraceptive method; amenorrhoea, for instance, was observed in 15% of our subjects. However, the modifications of menstrual cycles were slightly less frequent (in 147 (37.6%) out of 390 treated subjects). The most annoying symptoms indeed were amenorrhoea, prolonged cycles, and intermenstrual bleeding.

These alterations are apparently related to the anti-oestrogenic effect of the progestogen and are shown by those subjects more sensitive to such action. Furthermore, our macroscopic and microscopical observations on ovaries of subjects treated with 0.5 mg. of chlormadinone daily, who presented prolonged menstrual cycles or amenorrhoea, showed that ovulation was inhibited. A marked effect of the compound at the endometrium stroma and glands was also evident (Zañartu *et al.*, 1967b).

These findings help us to understand why additional oestrogen therapy given for a few days for bleeding and cycle regulation could eventually reverse the effect in cervical mucus of chlormadinone 0.5 mg. daily, and yet preserve the main contraceptive effect of the therapy at other levels of the reproductive system (endometrium, endosalpinx).

The gratifying action of the accessory oestrogens by correcting uterine bleeding and regulating cycles significantly helps to improve the acceptability of this valuable contraceptive method. It has also been valuable in improving the acceptability of other progestogens in microdoses.

Summary

Fifty women presenting alterations of uterine bleeding and menstrual cycles while using oral continuous 0.5-mg. chlormadinone tablets for fertility control were given additional oral oestrogens to correct the condition. Conjugated oestrogens 2.5- or 5-mg. tablets were given for five to seven days in each calendar month. Ethinyloestradiol 0.05 mg. was also used when well tolerated. The continuous oral administration of chlormadinone tablets was maintained.

Accessory oestrogens were useful in correcting the bleeding and cycle disturbances resulting from the anti-oestrogenic effect of microdoses of oral chlormadinone without interfering with the fertility inhibition effect. It is suggested that the addition of oral oestrogens is useful to improve acceptability of continuous chlormadinone in microdoses as a contraceptive while maintaining the outstanding properties of this therapy.

Chlormadinone acetate 0.5-mg. tablets were generously donated by Syntex International (Mexico) and E. Merck-Darmstadt (Germany). We are indebted to Ayerst Laboratories Inc. (New York) for the supply of conjugated oestrogens (Premarin).

Transfer Factor (Diffusing Capacity) for the Lung in Simple Pneumoconiosis of Coal Workers

J. P. LYONS,* M.D.; W. G. CLARKE,† M.S.R., A.R.P.S.; A. M. HALL†; J. E. COTES,† D.M., M.R.C.P.

Brit. med. J., 1967, 4, 772-774

Established simple pneumoconiosis of coal workers is accompanied by a widening of the alveolar-arterial tension difference for oxygen (Brasseur, 1963) and a minimal reduction in the transfer factor (diffusing capacity) for the lung, measured by the steady state carbon monoxide method (Podlesch, Stevanovic, and Ulmer, 1966). These changes are probably due to uneven distribution of pulmonary ventilation and perfusion. The finding of a low transfer factor by this method is not necessarily evidence for a transfer defect; this is better assessed by the single-breath carbon monoxide method, which is less susceptible to the effects of uneven distribution. With this method a number of workers have found a proportion of men with simple pneumoconiosis to have a transfer defect (for references see Nicaise, Vereerstraten, and de Clercq, 1967); the change may be accompanied by an increase in the quantity of reticulum in the lung parenchyma (Gaensler, Hoffman, and

Elliott, 1960). A weak association with the punctate or pin-head type of radiological opacities has been suggested by Engle and De Coster (1965). The present observations on men attending a pneumoconiosis medical panel appear to confirm this finding, which is also supported by recent work from Belgium (L. Billiet, personal communication to J. E. C.).

Subjects and Methods

Over a period of 16 months men attending the Pneumoconiosis Medical Panel, Cardiff, who were thought to have simple pneumoconiosis of a pin-head type (punctiform opacities up to 1.5 mm. in diameter (International Labour Office, 1959)) together with some of a micronodular type (opacities of 1.5-3 mm. in diameter) were referred to the Pneumoconiosis Research Unit for assessment. Here the chest radiographs were read in duplicate by an independent observer (W. G. C.); respiratory symptoms were assessed by use of the M.R.C. Respiratory Questionary (Medical Research Council, 1960); and measurements were made of ventilatory capacity,

† Pneumoconiosis Research Unit of the Medical Research Council, Llandough Hospital, Penarth, Glamorgan.

Requests for reprints and for details of the physiological results should be addressed to Dr. Cotes.

lung volumes, and transfer factor (single breath for carbon monoxide), standard methods being used (Cotes, 1965; Meade *et al.*, 1965; International Labour Office, 1966). For each subject the findings on assessment of lung function were reported on at the time by one of us (J.E.C.) as being within the normal range or showing nonspecific changes, or as showing a ventilation defect of an obstructive type (low F.E.V., high R.V./T.L.C., and impaired mixing of inspired gas, but normal T.F. and T.L.C.), a transfer defect (low T.F. with normal or reduced T.L.C. and no evidence for airway obstruction), or possible emphysema (low F.E.V. and increased T.L.C. with or without a reduced transfer factor).

Results

Forty-seven subjects were thought to have simple pneumoconiosis involving all rib spaces in at least one lung (categories 2 and 3 of the International Labour Office classification). Of these men, on the basis of the first reading of the chest radiograph by W.G.C., 16 were thought to have only pin-head opacities, 11 only micronodular opacities, and 20 mixed opacities or additional lesions. The findings for the subjects classified in this way are summarized in Table I. The results of the lung function tests for the subjects who appeared to have simple pneumoconiosis of a pure pin-head or a pure micronodular type are reported in greater detail in Table II.

* P < 0.01. † P < 0.05.

This shows that the mean transfer factor for the men with the pin-head opacities is significantly less than that for the men with the micronodular opacities. The other findings are within the normal range.

In view of this result the x-ray films were re-read by W.G.C., who at no time had knowledge of the lung function findings. His readings differed from those on the first occasion only to the extent that two of the men initially graded as pure pin-head were now thought to have mixed pin-head and micronodular opacities. In both of these men the transfer factor was near to the average for their age and height. In addition the data were examined with respect to smoking habits, when it was found that the proportion of smokers among the men with the pin-head opacities (13/16) was higher than among those

with the micronodular opacities (3/11). The smokers had lower values for the transfer factor than the non-smokers and ex-smokers (mean difference associated with smoking 6.2 ml./min./mm. Hg, P < 0.05). However, the transfer factors for both the smokers and the non-smokers and ex-smokers were, on average, lower in the men with the pin-head opacities than in those with the micronodular opacities; the overall difference after adjusting for smoking was 5.4 ml./min./mm. Hg (P ≈ 0.07).

Discussion

The subjects for this study differ from the general population of coal miners in that they were referred after attendance at the Pneumoconiosis Medical Panel. The group may therefore be biased in two ways: (1) with respect to men having respiratory symptoms, because such men may be more likely to attend on their own initiative than men without symptoms; and (2) with respect to the extent of the radiological abnormality, because men with dense or progressive lesions are likely to be recalled to the Panel at more frequent intervals than those with less pronounced pneumoconiosis. However, that the former selective process was operating to a comparable extent for the men with both pin-head and micronodular opacities is suggested by the similarity of their average grades for both breathlessness and bronchitis (Table I). Therefore the finding for the transfer factor of a lower average value in the pin-head cases is unlikely to be biased on this account.

The cause for the low transfer factor is not known; it may be related to the dust in the lung or the reaction of the lung tissue. For example, it may be a result of more dust being present in the lung with the pin-head lesions than in one where the micronodular lesions predominate. Evidence on this aspect is so far incomplete (Rossiter *et al.*, 1967), but it is relevant that the average periods of work underground (Table I) and of work on the coal face do not differ to a material extent between the two groups of men. The nature of the reaction in the lung tissue in the pin-head cases is also unknown. The radiological appearance on a good-quality x-ray film is often an overall obscuration of the lung markings and of the "black" air spaces by the minute opacities, particularly at the lung bases. In addition there may be some linear opacities. These findings are suggestive of changes in the lung parenchyma, but the number of cases that were classified by their type of pneumoconiosis during life and have since come to necropsy is not yet large enough for a conclusion to be reached on this point.

Any morphological differences which may exist are unlikely to be related to diffuse infiltration of the rheumatoid type, since the serum titres for aggregated human gamma-globulin show little difference between the pin-head and the micronodular cases. In addition, the rate of progression to massive fibrosis, which may be dependent on this process (Wagner and McCormick, 1967), is if anything less for the pin-head cases. These points need to be clarified by a longitudinal study. In addition the apparent absence of a relation between the low transfer factor and breathlessness or other symptom requires examination by study of both these subjects in more detail, and other subjects selected by a process of random sampling from among men with simple pneumoconiosis.

Summary

Among men attending a pneumoconiosis medical panel a gas transfer defect of the lungs was observed in 10 out of 16 with simple pneumoconiosis whose opacities were of a pure pin-head type, but in none of 11 men whose opacities were of the micronodular type.

We are indebted to Dr. J. Watkins-Pitchford, Chief Medical Officer, Ministry of Social Security, and to members of the

Pneumoconiosis Medical Panel, Cardiff, for referral of cases; to Messrs. P. D. Oldham and G. Berry for statistical advice; and to Miss E. Dawkins for technical assistance.

Outbreak of E.C.H.O. Virus Type 30 in a General Practice

D. H. IRVINE,* M.D.; A. B. H. IRVINE,* M.B., CH.B.; P. S. GARDNER,† M.D., DIP.BACT.

Brit. med. J., 1967, 4, 774-776

For many years E.C.H.O. viruses have been known aetiological agents in human disease, particularly aseptic meningitis; examples include type 4 (Chin *et al.*, 1957), type 6 (Kibrick *et al.*, 1957), and type 9 (Tyrrell and Snell, 1956). One of the latest to be linked with aseptic meningitis is type 30, described in Scotland originally as the "Frater virus" (Duncan, 1960). A virus now known to be identical was described in the United States as the "Bastianni virus" (Plager and Decher, 1963).

E.C.H.O. virus type 30 was first incriminated in illness in this country in 1950-60 and has been encountered only occasionally between 1960 and 1964 (Grist and Bell, 1967). Current information on symptomatology is based on isolated cases seen in hospital practice. In this communication we describe an outbreak of a febrile illness observed in a general practice for which there is evidence that the causal agent may have been E.C.H.O. virus type 30.

Present Investigation

The practice has two principals and a list of approximately 5,140 patients. Though the majority of patients are resident in Ashington, a colliery town with a population of 28,000 people, a considerable number live either in the adjacent urban

area of Stakeford, which lies on the opposite bank of the River Wansbeck, or in one of five near-by villages. The practice boundary is within a 3-mile (5-km.) radius from the centre of Ashington (see Fig.).

The outbreak began in mid-June 1966, when two children presented within a day or two of each other a clinical picture suggestive of aseptic meningitis. Faeces were sent for laboratory examination, but before the results became available two further cases were seen, though the illness was less severe. As it was now evident that an unusual illness was prevalent in the practice, arrangements were made to widen the field of study. It was agreed to observe any new patients presenting with a febrile complaint in whom it was impossible initially to make a definite diagnosis or who had symptoms similar to those seen in the earlier cases. This system of screening was thought desirable since no pathogen had been identified at that stage. It was anticipated that in some cases an alternative diagnosis would emerge; in the event these cases, with one exception, were grouped together before individual laboratory results became available (group C below).

Laboratory Methods.—Specimens of stool were taken from all suspected cases. On arrival in the laboratory these specimens were emulsified in a 10% suspension and centrifuged. Then 0.2 and 0.1 ml. respectively were inoculated into two monkey-kidney and two Hep. 2 tissue culture tubes. Tissue culture tubes were examined daily; suspected virus agents were passaged into fresh tubes and identified by neutralization against specific antisera. Details of the laboratory procedures used have been described (Gardner *et al.*, 1961; Gardner and Cooper, 1964).

Results

Altogether 46 patients were examined in the period from 10 June to 22 August. It has been found convenient to classify them into three groups as follows:

Group A: Twenty-two patients (9 female, 13 male) with a symptom pattern peculiar to the outbreak in whom E.C.H.O. virus 30 was isolated from faeces.

Group B: Four patients (all female) with similar clinical features as group A in whom no virus was found in faeces.

Group C: Twenty patients (7 female, 13 male) presenting with a febrile malaise and later shown to be suffering from another condition. E.C.H.O. virus type 30 was not identified in their faeces.

Distribution of cases within practice boundary.

* General Practitioner, Ashington, Northumberland.

† Consultant Virologist, Royal Victoria Infirmary and University of Newcastle upon Tyne.

For further analysis groups A and B have been added together. Table I shows the relation of the outbreak to time; the apparently sudden onset was noted by other practitioners in the town. The end-point appears to have been reached as quickly, since no patients with a typical history were seen after 22 August. In Table II the age distribution of those with suspected E.C.H.O. virus 30 infection is compared with the overall practice population. The attack rates reported should be viewed with caution, as a numerically undetermined fraction of the total practice list is distributed in the outlying villages (see Fig.), where no cases were seen. Thus the attack rates given are probably an underestimate of the true rate in Ashington itself (Table II).

TABLE I.—*Relation of Outbreak to Time*

	20 June	10 July	30 July	20 Aug.
No. of cases in groups A and B	4	9	10	3

TABLE II.—*Age Distribution of Cases and Practice Population*

Age	No. of Patients		Attack Rate/1,000
	Total Practice	Suspected E.C.H.O. Virus 30 Infection	
0-9 years	711	14	19.70
10-19 "	703	5	7.11
20-29 "	618	3	4.85
30-39 "	634	3	4.73
40-49 "	666	1	1.50
50+ "	1,805	0	—

The geographical distribution of cases is interesting (see Fig.). Clearly the outbreak was extremely local, since no cases were reported in outlying areas of the practice despite the very short distances involved. In four instances two people in the same household were affected. Similarly, two patients in group B were on friendly terms and in social contact with two others in group A. They, in turn, were neighbours of two additional families in group A, which suggests that groups A and B may have a common causal agent.

Cases in group C were distributed randomly throughout all geographical areas of the practice.

It may be helpful to consider the main clinical groups in greater detail.

Groups A and B

Both in children and in adults the principal symptoms included headache, malaise, muscle pains, vomiting, and abdominal pain. The duration of complaint varied in individual patients from one to seven days, with an average of three days. Invariably the illness was of rapid onset—a period of two to three hours—and caused most distress in the first 24 hours.

Headache and muscle pains were experienced by all patients; indeed, headache was often severe, and it was the commonest presenting symptom. Vomiting (18 cases) was often limited to the first day. Colicky abdominal pain (11 cases) was not associated with a change in bowel habit but gave rise to concern in two patients when generalized abdominal tenderness and guarding were observed for several hours. Photophobia (eight cases) never persisted more than 18 hours.

Examination usually revealed only tenderness of muscle on palpation and a temperature rising above 100° F. (37.8° C.) (19 cases). Neck rigidity (four cases) was marked in the first two patients of the series, while a fleeting macular rash was seen once—otherwise the skin was not involved.

Illustrative case summaries from group A are given.

Case 1.—A boy aged 11 years gave a three-day history of increasingly severe headache, photophobia, and nausea. Examina-

tion at the first visit showed no abnormal signs except a pyrexia of 101.2° F. (38.4° C.); later that day he became sick, while the headache was unabated. Neck rigidity and Kernig's sign were then present. Thereafter the clinical course was one of rapid improvement to full recovery within two days.

Case 2.—A girl aged 7 years attended school one morning feeling perfectly well, but had to return home at lunch-time because she suddenly developed intense headache and was unable to focus on the blackboard properly. In the afternoon she began to vomit. Examination revealed a temperature of 101.8° F. (38.8° C.), raised pulse rate, and slight neck rigidity. By evening the headache was subsiding; the following morning the child had fully recovered.

Case 9.—A married woman aged 33 became ill suddenly one afternoon complaining of intense headache, malaise, nausea, and quite severe abdominal pain. There was generalized muscle-aching. The following day she requested her doctor to visit because of intense pain in the right loin and right iliac fossa. Headache was still present, now with photophobia. Abdominal examination revealed marked tenderness and guarding in the right iliac fossa, and a diagnosis of appendicitis was considered. Next day a generalized macular rash was present for a few hours; the patient felt better, as both headache and abdominal pain were subsiding. Two days later, apart from slight weakness, recovery was complete.

Case 18.—A boy aged 9 years gave a four-day history of intermittent malaise, nausea, headache, and abdominal colic. On the day of consultation his headache had worsened and he said that light hurt his eyes. The only abnormal physical sign was a temperature of 98.6° F. (37° C.), though his mother had recorded a higher temperature earlier. He returned to normal health two days later.

Group C

This group comprises patients presenting with a nonspecific febrile illness, later, with four exceptions, to develop manifestations of other infections. Eight patients had upper respiratory infections or tonsillitis. Four with watery diarrhoea showed none of the other main clinical features described in groups A and B. A urinary infection in one child was confirmed by laboratory examination, and acute appendicitis was found at operation in an adult. The firm diagnosis of infection with E.C.H.O. virus 9 was made in another child and later supported by laboratory findings. E.C.H.O. virus 27 was isolated from a boy who later complained of headache; he lived in an outlying village thought to have escaped the outbreak of E.C.H.O. virus 30. Finally, there were the four patients in whom diagnosis was never made. All were young children, feverish one day and better the next, with no localizing symptoms or signs whatsoever.

Discussion

It is often tempting to suggest a cause-and-effect relationship when viruses are identified in patients presenting with an otherwise inexplicable febrile illness. However, there is evidence that the finding of E.C.H.O. virus 30 in this series is of aetiological significance. Thus the outbreak began at a time of year when overt infection with E.C.H.O. virus is known to be most common. Typically, children are principally affected, as we found. Furthermore, the cardinal symptoms described in suspected cases (groups A and B) differ little from those in illness caused by other E.C.H.O. viruses (Sanford and Sulkin, 1959) and contrast sharply with the diverse patterns in group C, with the exception of the boy excreting E.C.H.O. virus 27.

The precise geographical localization of the outbreak, the first to be described linked with E.C.H.O. virus 30 so far as we know, is reminiscent of another attributed to E.C.H.O. virus 9 which was confined to a new residential estate in North-east England (Wright *et al.*, 1961).

Our findings suggest that, though E.C.H.O. virus 30 has been found only sporadically over the last six years, it is not a new virus and adults have an immunity to it.

Summary

An outbreak of a febrile illness confined to a local geographical area within a general practice is described. E.C.H.O. virus 30 was isolated from faeces in a majority of cases. The illness was of rapid onset but lasted only a few days, and the principal symptoms included headache, muscle pains and malaise, vomiting, colicky abdominal pain, and photophobia. Evidence that E.C.H.O. virus 30 was of aetiological significance in the series is discussed. Although E.C.H.O. virus 30 has been found only sporadically over the last six years, the results suggest that it is not a new virus and that adults have an immunity to it.

We are indebted to the technical staff of the department of virology of the Royal Victoria Infirmary for their help.

Calf Muscle Denervation for Intermittent Claudication*

N. V. ADDISON,† M.B., F.R.C.S.

Brit. med. J., 1967, **4**, 776-778

It is now a well-established fact that the ideal treatment for femoropopliteal occlusions which cause intermittent claudication in the calf is a bypass graft. An autogenous saphenous vein is undoubtedly the best type of graft to use with good and lasting results (Darling *et al.*, 1967). The indications for inserting a graft usually depend on the individual surgeon, who may operate for intermittent claudication which is not particularly disabling. Others may limit the procedure to those with severe claudication, rest pain, or impending gangrene (Shucksmith and Addison, 1962). The reversed saphenous vein bypass graft is usually taken from the common femoral to the distal popliteal artery behind or below the knee joint. The problem arises when the distal popliteal artery is grossly diseased or totally blocked. Under these circumstances it may be possible to take the graft to the posterior tibial or peroneal arteries if the saphenous vein is left in situ. If both distal popliteal and tibial vessels are unsuitable for grafting then only palliative treatment can be considered. Claudication can be relieved or the claudication distance increased by inactivation of the calf muscles where the pain develops. Two operations can be performed to effect this inactivation, one by Achilles tenotomy (Boyd and Bloor, 1960) and the other by denervation of the calf muscles.

If these muscles are paralysed the patient learns to use other muscles, including the hamstrings, when walking. Learmonth and Slessor (1952) describe this procedure of myoneurectomy and claim that patients obtain a walking distance some five times greater than preoperative distances.

If the distal vessels are blocked and there is severe rest pain in the foot or calf then an above-knee or Gritti-Stokes amputation may be necessary, though a lumbar sympathectomy is well worth trying, especially if pain is relieved by a medical sympathectomy (Martin, 1963). Obviously rest pain cannot be relieved by inactivation of the calf muscles, but if it is localized to a small area in the foot, treatment by a selective peroneal or anterior tibial neurectomy may help.

I have adopted the method of calf muscle denervation for patients with popliteal or tibial occlusions, and for some older patients with calf pain, as an alternative to a bypass graft. This

paper is based on the first 40 denervations carried out during the past four years.

Cause of Ischaemic Pain in Calf Muscles

The cause of intermittent claudication is a relative anoxia of the muscles, and the importance of this anoxia was shown by Pickering and Wayne (1934). They found that by exercising muscles of an anaemic subject with no evidence of arterial disease characteristic pain of intermittent claudication could be produced. The clinical experiments of Lewis (1932) indicate that the direct cause of the pain is not oxygen lack itself but the stimulation of sensory nerves by the metabolic products of muscular activity. When the blood supply is inadequate and oxygenation therefore deficient, metabolic products accumulate. Lewis referred to the pain stimulus as "factor P." The nature of the chemical pain factor is unknown but is probably acid, and ingestion of sodium bicarbonate was found to increase the amount of exercise required to cause pain.

Nerve Supply of Calf Muscles

In a so-called motor nerve supplying a limb muscle at least 30 to 40% of the fibres are sensory in function and have their cell bodies in the dorsal root ganglia of the segmental nerves.

The endings of the afferent fibres in striated muscle vary a great deal in structure. The simplest ones are very fine non-myelinated nerve fibres with no specific ending. Some run in perivascular plexuses, and others are found in connective tissue, and it has been suggested that these are pain fibres (Bowden, 1960).

The medial popliteal nerve, arising from the fourth and fifth lumbar nerves and the first, second, and third sacral nerves, supplies the two heads of the gastrocnemius and the soleus. In the popliteal fossa it is concealed at first by the semi-membranosus and other hamstring muscles. It passes superficial to the popliteal vessels from the lateral to the medial side, and is thereafter found deep to the popliteus muscle under cover of the gastrocnemius and plantaris. Two branches arise in the fossa, one for each head of the gastrocnemius, and usually enter these muscles at the borders of the popliteal fossa. A nerve for

* Based on a lecture given at the invitation of the Professor of Surgery, Jefferson Medical College, Philadelphia, U.S.A., on 25 April 1967.
 † Consultant Surgeon, Royal Infirmary, Bradford.

the soleus enters the superficial surface of the muscle near its proximal border and a branch from the posterior tibial nerve (which begins at the distal border of the popliteus) enters the soleus on its deep surface near the middle of the leg. The soleus can never be completely denervated unless this branch is divided. At the inferior angle of the popliteal fossa the medial popliteal nerve gives off the sural nerve, which leaves the fossa by passing downwards between the two heads of the gastrocnemius and continues down the posterior aspect of the calf with the short saphenous vein.

Operative Procedure

The patient lies in a prone position under general anaesthesia which must be light; under no circumstances must a long-acting muscle relaxant be used, because the nerves are identified by pinching them with artery forceps to stimulate immediate contraction of the muscles. If these are paralysed by long-acting relaxants, then the calf muscle nerves cannot be properly identified and there is the danger of dividing the wrong nerve. The sural nerve can be mistaken for a nerve to the calf muscles, and if this is divided then anaesthesia will result on the lateral side and back of the distal third of the leg, ankle, and heel and on the lateral border of the foot.

An incision about 2 in. (5 cm.) in length is made in the midline in the lower part of the popliteal fossa. The deep fascia is divided and the heads of the gastrocnemius are held apart with a self-retaining retractor. Care must be taken not to damage the sural nerve or popliteal veins that may lie superficial to the medial popliteal nerve, which is identified before dissecting out the nerves to the muscles.

There are usually three nerves to be divided and ligated with thread (see Fig.). Coagulation diathermy should be avoided and

Operation of calf muscle denervation showing silk tapes around the nerves to the lateral head of gastrocnemius (a), the medial head of gastrocnemius (b), and the superficial part of soleus (c).

haemostasis should be complete before suturing the deep fascia and skin. If a lumbar sympathectomy is to be carried out then the patient is turned over and this is proceeded with. The patient is got out of bed as soon as he becomes fully conscious, the following day he is encouraged to walk up and down the

ward, and he is discharged 48 hours after operation. It is most important to walk immediately, wearing a firm crêpe bandage to support the calf.

Selection of Cases for Operation

Any patient with disabling claudication whose arteriogram showed occluded distal popliteal or tibial arteries was considered for muscle denervation, provided that the symptoms had been present for at least one year, as about 50 to 60% of patients with untreated claudication improve spontaneously up to 12 months after the onset, owing to the development of a collateral circulation. The presence of calcification on a plain radiograph of the lower limb was also thought to be unsuitable for a vein graft, though some surgeons do not regard calcification as a serious hazard.

It is important to select only those patients with pain in the calf. If claudication occurs in the buttocks and thighs as well then surgery of the aortoiliac region is necessary to relieve the pain. Unilateral calf claudication was desirable for a good result as it was in Boyd and Bloor's (1960) selection of cases for Achilles tenotomy. It is useful to choose a fairly intelligent patient who will understand the nature and purpose of the operation.

If the foot was cold then a lumbar sympathectomy was carried out at the same time as the denervation of the calf muscles.

Results and Follow-up

In the present series 40 patients have undergone calf muscle denervation, and two of these were bilateral. Their ages varied from 45 to 70 years, the majority being 55 to 64 (Table I). There were four failures in the first six months, due to poor selection of cases, and two of these failures had bilateral denervations.

TABLE I.—Age of 40 Patients Undergoing Calf Muscle Denervation

Age	45-54	55-64	65-70
No. of patients	8	28	4

The remaining 36 patients have been followed up at regular intervals for a minimum of six months and a maximum of 44 months (Table II). There have so far been no deaths in the series.

TABLE II.—Follow-up of 36 Patients After Calf Muscle Denervation

Time (years)	Less than 1	1-2	2-3	Over 3
No. of patients	8	12	12	4

The claudication distance preoperatively was recorded and in 18 patients was 50 to 100 yards (45 to 90 metres), and in 22 patients 101 to 200 yards (91 to 180 metres) (Table III). After operation patients were seen at three-monthly intervals and asked how far they were able to walk on the flat before pain developed. The distances recorded were based on the patient's

TABLE III.—Claudication Distance Before and After Muscle Denervation

Distance		No. of Patients
Yards	Metres	
<i>Before muscle denervation</i>		
50-100	45-90	18
101-200	91-180	22
<i>After muscle denervation</i>		
No change		4 (10%) including 2 bilateral
0-300	0-275	6 (15%)
301-600	276-550	8 (20%)
601-2,000	551-1,830	12 (30%)
No limit		10 (25%)

subjective assessment, which is an inaccurate method of judging results, especially in estimating walking distances less than 500 yards (455 metres). When a patient stated that he could walk over half a mile (800 metres) or indefinitely without pain, the recording of results was made much easier. In the earlier cases an attempt was made to estimate improvement by recording pain when patients were asked to step up and down on to a box 1 ft. (30 cm.) high before and after operation, but the test was not helpful and was therefore abandoned.

Preoperative arteriography carried out in 38 patients showed that 32 had unilateral femoropopliteal blocks, the remaining six being occluded in both legs. In the bilateral occlusions there were four early failures and the other two were not very successful, as their increased walking distance was less than 300 yards (275 metres).

In 20 patients there was associated aortoiliac disease but not occlusions, but this did not appear to have any effect on the final results in 17. In the other three patients there was only slight improvement postoperatively.

Those patients with the most severe disease demonstrated radiologically and a preoperative claudication distance of less than 100 yards (90 metres) did not benefit from surgery as well as those with less severe disease and a longer claudication distance up to 200 yards (180 metres).

It is apparent that the early results are most encouraging, and that at least 70% are able to walk 500 yards (455 metres) or more without pain, and that the long-term results are satisfactory up to three years after operation (Table III).

Complications of Muscle Denervation

There were two cases of deep thrombophlebitis seen earlier on in the series and both responded rapidly to anticoagulant therapy. One case of deep thrombophlebitis in the calf was seen 18 months after operation, but the patient had been able to walk indefinitely without pain after operation until the onset of the attack, which resolved with rest and a firm supporting bandage. One case of pulmonary embolism was recorded in one of the patients suffering from deep thrombophlebitis.

In one case early on in the series a haematoma needed to be evacuated surgically, and in another patient the lateral popliteal nerve was accidentally crushed, but this recovered fully after almost a year. Complete haemostasis, a firm bandage, and immediate ambulation help to eliminate any complications that may arise.

Discussion

The results in this series would appear more favourable than those undergoing Achilles tenotomy reported by Boyd and Bloor (1960). In 72 patients they reported complete relief of pain in only 22%, temporary relief for one year in 21%, and immediate failure in 57%. Claudication developing elsewhere in the same leg or other leg accounted for 50% of their immediate failures. They suggested that their results could have been better with a more careful selection of cases for operation.

Disadvantages of Achilles tenotomy include early union by fibrous tissue of the ends of the divided tendon leading to a return of symptoms. Another disadvantage is the difficulty of walking immediately, as patients must learn to stand with confidence before trying to walk. After calf muscle denervation they can walk immediately, though they all have a slight limp and a few have needed to use a stick, but all regarded this as a small price to pay in return for relief of pain.

Muscle denervation has a more logical approach to the relief of pain than Achilles tenotomy, and its effective action may be due to three factors: (1) paralysis of the gastrocnemii and part of the soleus muscles with wasting; (2) division of somatic afferent pain fibres in the mixed motor nerves; and (3) division of sympathetic afferent pain fibres in the mixed motor nerves. It is possible that division of the motor nerves destroys sympathetic as well as somatic afferent fibres, and this relieves pain to some extent. Relief of intermittent claudication after a lumbar sympathectomy alone may be due to division of afferent pathways, since some patients claim that though their halting distance is unchanged the severity of the pain is diminished (Myers and Irvine, 1966). A lumbar sympathectomy was carried out simultaneously in 12 of the 40 denervations, and it was recorded that six of these patients could walk indefinitely without pain after operation.

In assessing the results of calf muscle denervation it is stressed that improvement was based entirely on the patient's subjective assessment of walking distance without pain. Twenty-two patients (55%) stated emphatically that they could walk about half a mile (800 metres), or indefinitely, and these were judged to be very successful. A further 8 (20%) claimed that their walking distance had increased up to three times their preoperative distance. In view of the difficulty of estimating short distances with any accuracy, these results were not judged as successful as those who could walk half a mile (800 metres) or indefinitely. On the other hand, these eight patients definitely benefited from surgery, compared with the remaining six who had only slight improvement of walking distance up to 300 yards (275 metres).

Summary

Patients with intermittent claudication in the calf caused by femoropopliteal occlusions are usually treated with bypass vein grafts, but this procedure is impracticable if the distal popliteal and tibial arteries are grossly diseased or blocked.

An alternative operation of calf muscle denervation is described in 40 patients who have been followed up for six months to over three years. There were four early failures due to poor selection of patients for this procedure.

Early results are encouraging, and 70% of patients are able to walk at least 500 yards (455 metres) and 25% are able to walk indefinitely without pain. The long-term results would appear to be satisfactory.

Calf muscle denervation is a simple operation with little morbidity, and is advised for inoperable femoropopliteal occlusions. The operation can be performed selectively in operable cases in the older age group.

I wish to thank Mr. P. Harrison for the illustration, and Mr. C. L. O. Macalister for his helpful advice.

Gynaecomastia in Chronic Renal Failure

R. M. LINDSAY,* M.B.; J. D. BRIGGS,* M.B., M.R.C.P.; R. G. LUKE,* M.B., M.R.C.P.

I. T. BOYLE,* M.B., B.Sc., M.R.C.P.; A. C. KENNEDY,* M.D., F.R.C.P.

Brit. med. J., 1967, 4, 779-780

Gynaecomastia is associated with several clinical conditions, but so far as we can ascertain the only report of it occurring in chronic renal failure is that of Shaldon (1966). He mentions gynaecomastia in patients undergoing regular dialysis treatment, and attributes this to the refeeding of malnourished uraemic patients at the start of dialysis. It does not seem to have been observed in uncomplicated chronic renal failure without regular dialysis treatment.

The presence of gynaecomastia has been observed in all four of the male patients at present undergoing regular dialysis treatment in the renal unit of the Glasgow Royal Infirmary and in two other patients with chronic renal failure.

Case Reports

The clinical and biochemical data of the six patients are summarized in Tables I and II. The patients receiving regular dialysis treatment each had two 10-hour haemodialyses a week by means of a Kolff twin coil dialyser incorporating a 0.9-sq. m. cellophane coil (Chron-a-Coil, Baxter).

The existence of gynaecomastia was determined, and agreed on by two observers, by the presence of readily palpable concentric increase in the subareolar tissues. The features of the gynaecomastia in each patient are summarized in Table III.

No patient had any clinical evidence of hepatic or of other systemic disease unrelated to the renal failure. Standard liver-function tests, serum transaminases, and a B.S.P. (bromsulphalein) excretion test were carried out on each patient. These estimations were performed by routine methods in the biochemistry department of this hospital. In no patient was any abnormality of these tests detected.

Case 1.—A bachelor aged 21 had noticed better general health, a great increase in libido, and improvement in secondary sexual characteristics since he started regular dialysis treatment. One month after beginning regular dialysis treatment he complained of considerable tenderness in the areolar region. Examination

revealed bilateral tender gynaecomastia. This had diminished considerably but was still present.

Case 2.—A man married for 13 years, with no family, had from 1962 onwards experienced a decline in his general health and also in libido but without impotence. Since starting regular dialysis treatment there has been marked improvement in health but not in libido. At the time of writing he was impotent. Two months after his first dialysis he complained of tenderness in the nipple area, and examination revealed slight bilateral tender gynaecomastia. This had now almost disappeared.

TABLE III.—Characteristics and Duration of Gynaecomastia

Case No.	Features of Gynaecomastia
1	Bilateral and tender—appeared after 1 month of R.D.T.—lasted 9 months—now virtually absent
2	Bilateral and tender—appeared after 2 months of R.D.T.—lasted 9 months
3	Bilateral and tender—appeared after 1 month of R.D.T.—diminished but still present after 8 months
4	Unilateral and tender (left side)—appeared after 1 month of R.D.T.—lasted 3 months
5	Bilateral and tender—lasted 3 weeks—not on R.D.T.
6	Bilateral and non-tender—duration unknown—not on R.D.T.

Case 3.—A married man with two children, aged 5 and 7, had experienced a progressive decline in health from January 1966 in association with loss of libido and impotence. After one month of regular dialysis treatment libido and potency returned. At this time he also noticed tenderness in the nipple region. Examination revealed gynaecomastia, which, though considerably reduced, was still present after eight months (Figs. 1 and 2).

Case 4.—A married man with a child aged 6 experienced a decline in health plus loss of libido from July 1966. There was no impotence. He started regular dialysis treatment in January 1967, and thereafter he had a rapid increase in libido. One month after starting regular dialysis treatment unilateral slightly tender gynaecomastia was observed. This completely regressed after three months.

Case 5.—This patient was a bachelor aged 24. In July 1966, after a six months' decline in health, he was diagnosed as suffering from chronic renal failure. He improved with a 20-g. protein diet, but in December 1966, because of considerable proteinuria (11.8 g./24 hours), the dietary protein was increased to 30 g. a day.

* University Department of Medicine, Glasgow Royal Infirmary, Glasgow C.4.

TABLE I.—Clinical and Biochemical Data of Patients Receiving Regular Dialysis Treatment (R.D.T.)

Case No.	Age	Diagnosis	Duration of R.D.T. (months)	Average Pre- and Post-dialysis		Other Management	Comment
				Blood Urea (mg./100 ml.)	Serum Creatinine (mg./100 ml.)		
1	21	Renal hypoplasia	10	140→46	12.0→5.7	40-g. protein diet	Rehabilitated
2	38	Chronic G.N.	12	182→66	11.4→5.4	40-g. protein diet. Methyl dopa	Partially rehabilitated
3	36	Chronic G.N.	9	147→42	11.5→6.0	40-g. protein diet	Rehabilitated
4	28	Chronic G.N.	6	118→45	7.5→4.2	40-g. protein diet. Methyl dopa	Partially rehabilitated

G.N. = Glomerulonephritis.

TABLE II.—Clinical Data of Patients not Receiving Regular Dialysis Treatment

Case No.	Age	Diagnosis	Creatinine Clearance (ml./min.)	Blood Urea (mg./100 ml.)	Comment
5	24	Chronic G.N.	6.4	170	Hypertensive. Being prepared for R.D.T. On Glavanetti diet + methyl dopa
6	59	Pyelonephritis. Hydronephrosis. Urethral stricture	4.7	180	Hypertensive. Has perineal urethrostomy. On 40-g. protein diet + methyl dopa

Creatinine clearance at that time was 9.2 ml./min. In April 1967 he was feeling well but complained of nipple tenderness, and slight bilateral gynaecomastia was evident on examination. This disappeared after three weeks. By May he became unwell again with nausea and vomiting. His creatinine clearance had fallen to 6.4 ml./min. and his haemoglobin was 7.1 g./100 ml. He was transfused, and was started on a Giovanetti-type diet plus methionine supplements. This led to considerable improvement in his symptoms plus a recurrence of the nipple tenderness, which lasted for about 10 days and was uncomfortable, but there was no convincing gynaecomastia.

Case 6.—This patient, a married man with five children, had long-standing chronic pyelonephritis with hydronephrosis secondary

FIG. 1.—Anteroposterior view of gynaecomastia in Case 3 after eight months' regular dialysis treatment.

to a urethral stricture. The latter was of such a degree that six years ago a perineal urethra was fashioned for him. His renal disease was complicated by calculus formation. His general health was poor. His creatinine clearance was 4.7 ml./min. Therapy consisted of a 40-g. protein diet plus methyl dopa 250 mg. t.i.d. to control his hypertension. In April 1967 he was admitted for blood transfusion. During this admission gynaecomastia was noted to be present, but as the patient had not noticed this we are unaware of its duration.

Discussion

According to Paulsen (1962) the clinical conditions most commonly associated with gynaecomastia are: normal puberty, hypergonadotrophic hypogonadism (for example, Klinefelter's syndrome, functional prepubertal castrate); male pseudohermaphroditism, "refeeding gynaecomastia" (for example, recovery from generalized malnutrition, liver cirrhosis, digitalis therapy, pulmonary tuberculosis); testicular tumours (for example, choriocarcinoma, interstitial cell adenomas); spinal cord lesions; hyperthyroidism, hypothyroidism; Hodgkin's disease; and bronchogenic carcinoma.

Four of the six patients were on methyl dopa at the time the gynaecomastia was observed. We can find no reference that gynaecomastia may be caused by this drug, though breast enlargement and lactation has been reported as a rare side-effect in females (Pettinger *et al.*, 1963). No other drugs were being given to the patients during this time. We think it unlikely, therefore, that drugs could be implicated in the production of the gynaecomastia in these patients.

The gynaecomastia observed in Cases 1 to 4—that is, those receiving regular dialysis treatment—can probably most readily be explained on the basis of "refeeding" after the start of treatment. This is further suggested by the rapid increase in libido and potency. Presumably, as a consequence of chronic renal insufficiency plus a low protein intake, which are both likely to cause depression of pituitary gonadotrophins (Paulsen, 1962), testicular function is quiescent. With the beneficial

FIG. 2.—Lateral view of gynaecomastia in Case 3 after eight months' regular dialysis treatment.

effects of regular dialysis treatment, plus the increase in daily protein intake allowed by this regimen, a "second puberty" ensues, and this may often lead to a transient gynaecomastia.

The gynaecomastia in Cases 5 and 6, however, is without obvious explanation.

Conclusion

It would appear that transient gynaecomastia may occur not uncommonly in male patients with chronic renal failure during the early stages of regular dialysis treatment. It is also apparent that it may occur in similar patients not receiving this treatment. Further investigation into the incidence of its occurrence in chronic renal failure, and into its precise pathogenesis, is indicated.

ABO Blood Groups and Infantile Hypertrophic Pyloric Stenosis

J. A. DODGE,* M.B., B.CH., M.R.C.P.ED., D.C.H.

Brit. med. J., 1967, 4, 781-782

An association between blood group A and cancer of the stomach was first reported by Aird, Bentall, and Fraser Roberts (1953). Further associations between blood groups and gastrointestinal disorders have since been described (Clarke, 1964a). This paper reports an investigation into the ABO blood group distribution and salivary secretor status of patients with infantile hypertrophic pyloric stenosis.

Material

The ABO groups of 303 patients with infantile hypertrophic pyloric stenosis were determined as part of a follow-up study. In all instances the diagnosis had been confirmed at operation, and all patients were resident in Belfast or its immediate environs at that time.

Information concerning the distribution of the ABO blood groups in Belfast was obtained from the Serological Population Genetics Laboratory (A. C. Kopeć, personal communication, 1967) and used for control purposes.

The salivary secretor status of 288 patients with infantile hypertrophic pyloric stenosis was investigated. Control data were obtained from 96 children admitted to hospital for tonsillectomy or adenoidectomy and from 435 children attending school dental clinics in Belfast.

Methods

Blood samples were obtained by venepuncture except in a small number of infants, when capillary blood obtained by heel stab was used. In all cases a full explanation was given to the parents, and in no instance was permission for blood sampling refused. ABO blood groups were determined by the tube method.

Samples of saliva were examined for the presence of ABH blood group substances. The children were asked to rinse their mouths with water before saliva was collected into plastic specimen jars and transferred to test-tubes. In the case of infants saliva was aspirated gently with a 2-ml. syringe. The tubes were partly immersed in a boiling water-bath for 10 to 20 minutes before being stoppered and stored in a refrigerator at 4° C. until testing, which was usually within 24 hours. Saliva specimens were tested for the presence of A, B, and H substances by the method of Dunsford and Bowley (1955). The anti-A and anti-B sera were provided by the N.I. Blood Transfusion Service, whose laboratories also prepared and extracted anti-H from the seeds of *Ulex europaeus*. Absence of inhibition of agglutination of O cells by anti-H serum diluted 1 in 8, in the presence of a 1 in 2 dilution of saliva, was accepted as a negative result. (This dilution was found to be the most satisfactory which could give a clear-cut result on microscopical examination.)

After the first 70 tests had been performed checking for A and B substances was omitted on most occasions because it was found that in all cases of secretion of A or B substances H sub-

stance could also be detected. Since the concentration of H substance in the saliva of group B secretors is often lower than in those of group O (Clarke, McConnell, and Sheppard, 1960), all non-secretors of known blood group B were reviewed a second time and their salivas examined for the presence of both B and H antigens; no trace of either could be detected in any instance.

Results

The distribution of ABO blood groups among 303 patients with infantile hypertrophic pyloric stenosis compared with controls is shown in Table I. It is evident that there were an unexpectedly large number of patients of blood group B in this series and a correspondingly small representation of patients of blood group A. These findings are statistically significant ($P=0.001$). Group O patients formed approximately the same proportion of the series as of the controls, and the slight excess of group AB patients was too small in actual numbers to justify further consideration. The relative incidence of pyloric stenosis in persons of groups O and B compared with group A is given in Table II. The χ^2 was calculated by the method of Woolf (1955) and is again statistically significant.

TABLE I.—Distribution of ABO Blood Groups in 303 Patients with Infantile Hypertrophic Pyloric Stenosis Compared with Distribution in Controls

Group	Patients		Controls	
	Total No.	Percentage	Total No.	Percentage
O	170	56.11	15,269	55.01
A	76	25.08	9,168	33.03
B	45	14.85	2,624	9.45
AB	12	3.96	696	2.51
Total	303	100	27,757	100

$\chi^2 = 18.228$. D.F. = 3. $P < 0.001$.

TABLE II.—Relative Incidence of Infantile Hypertrophic Pyloric Stenosis in Children of Groups O and B, Compared with Incidence of 1.0 in Persons of Group A

Group	Relative Incidence	χ^2	P
O	1.40	5.96	0.02 > P > 0.01
B	2.10	15.27	< 0.001

The incidence of salivary non-secretors was lower than expected, but this is not significant ($0.1 < P < 0.2$) (Table III). The secretor status of the blood group controls is not known, so Table IV gives a calculated expected incidence of each blood group and secretor type combination, compared with the observed incidence in infantile pyloric stenosis, but no claim is made that these results are statistically valid.

TABLE III.—Distribution of Secretor Status in 288 Patients with Infantile Hypertrophic Pyloric Stenosis Compared with 531 Controls

	Patients	Percentage	Controls	Percentage
Secretor ..	226	78.47	390	73.45
Non-secretor ..	62	21.53	141	26.55
Total ..	288	100	531	100

$\chi^2 = 2.52$. D.F. = 1. $0.1 < P < 0.2$.

* Department of Child Health, the Queen's University of Belfast, Northern Ireland.

TABLE IV.—Distribution of ABO Blood Groups and Secretor Status in 288 Patients with Infantile Hypertrophic Pyloric Stenosis Compared with Expected Incidence in the Control Population*

Blood Group and Secretor Type	Expected Percentage in Controls	Observed Percentage in I.H.P.S.
Group O secretor	40.40	42.71
Group O non-secretor	14.61	11.81
Group A secretor	24.26	21.88
Group A non-secretor	8.77	4.17
Group B secretor	6.94	10.76
Group B non-secretor	2.51	4.51
Group AB secretor	1.85	3.12
Group AB non-secretor	0.66	1.04

* Blood group data were obtained from the Serological Population Genetics Laboratory. As the secretor status of these donors was not known, the expected incidence of each blood group and secretor/non-secretor combination has been calculated by using the observed secretor/non-secretor ratio in the child controls referred to in Table III.

Discussion

It has been stated that infants with hypertrophic pyloric stenosis have a high incidence of peptic ulcer in later life (Bendix and Necheles, 1947; Belding and Kernohan, 1953; Hecker, Wenz, and Brückner, 1966), though control data are difficult to obtain. If this were so one might expect to find an increased incidence of blood group O among babies with pyloric stenosis, such as is seen in adult ulcer patients. Indeed, it is possible that the pyloric hypertrophy develops in association with a juxta-pyloric ulcer occurring in the neonatal period, for there is no apparent reason why newborn infants should not be equally subject to peptic ulcer as adults (Polacek and Ellison, 1966). Burge, Gill, and Lewis (1963) suggest that hypertrophic pyloric stenosis in adults is always related to ulceration in or near the pylorus, a view which was earlier put forward by Golden (1937).

The present series certainly demonstrates an excess of group O patients when compared with those of group A, of the same order as that seen in several series of duodenal ulcer patients (Clarke, 1964b). However, this apparent excess of group O patients is actually a reduced incidence of persons of group A, a deficiency which is largely compensated by the marked increase in the proportion of group B patients in the series. Thus group A may be regarded as in some way protecting against the development of infantile pyloric stenosis—or, alternatively, both group O and group B infants are at greater risk than those of group A (Table II). Though the group O babies would also have a theoretically greater chance of developing an ulcer, no association between group B and peptic ulcer has been reported.

Non-secretors of group O are particularly liable to develop peptic ulcers (Clarke, Price Evans, McConnell, and Sheppard, 1959). In this series secretor status appears to be unrelated to the occurrence of pyloric stenosis.

The blood group distribution seen in infantile hypertrophic pyloric stenosis may be compared with that found in relation to the production of alkaline phosphatase by the gut after a fatty meal. It has been shown that persons of groups O and B produce more of this type of alkaline phosphatase than those of groups AB and A (Arfors, Beckman, and Lundin, 1963a). Thus

individuals of groups O and B not only produce more intestinal alkaline phosphatase than those of group A but would also appear to have a greater susceptibility to infantile pyloric stenosis. It is known that secretors of ABH substances produce more intestinal alkaline phosphatase than non-secretors of the same blood group (Arfors, Beckman, and Lundin, 1963b). Thus secretors of groups O and B produce most alkaline phosphatase, followed by O and B non-secretors, with group A non-secretors producing least of all. Though not statistically significant, such evidence as this present study provides does suggest that (except in the case of group A) salivary ABH secretors are at greater risk of developing infantile pyloric stenosis than non-secretors. The series is too small to allow firm conclusions to be drawn in this respect, and no information is yet available about the secretion of alkaline phosphatase in pyloric stenosis.

Summary

Analysis of the ABO blood groups of 303 patients with infantile hypertrophic pyloric stenosis showed a significantly low incidence of group A compared with controls. The blood group distribution is discussed in relation to the quantitative differences in intestinal alkaline phosphatase found in persons of different ABO groups.

Investigation of salivary ABH secretor status showed no significant difference between patients with infantile pyloric stenosis and controls.

I thank the consultant paediatricians and surgeons of the Royal Belfast Hospital for Sick Children, Belfast City Hospital, and the Ulster Hospital for allowing me to review patients under their care; Professor I. J. Carré for his helpful advice and encouragement; Dr. M. C. Huth and Mr. T. Wilson for supplying anti-H serum; Dr. J. M. Bridges for laboratory facilities and assistance; Dr. J. D. Merrett for advice on statistical methods; and Dr. A. L. Walby, Schools Medical Officer, and the dental surgeons of the School Health Service, Belfast, for providing control specimens of saliva.

Medical Memoranda

Neoplasia Complicating Uretero-sigmoidostomy

Brit. med. J., 1967, 4, 783-784

There are reports in the literature of 17 patients who developed neoplastic lesions at or close to the site of anastomosis after transplantation of the ureters to the sigmoid colon. Urdaneta *et al.* (1966) and Kozak *et al.* (1966) have published reviews and discussed the problems involved. Two further cases are here described.

CASE 1

A 26-year-old man had his ureters transplanted into the sigmoid colon in 1951, when aged 10 years, for incontinence secondary to an epispadias. Five years later he passed a small amount of blood per rectum. Sigmoidoscopy showed evidence of proctitis, and this was presumed to be the cause. He remained well until 1964, when once again he passed blood, this time from some small piles. The following year he was admitted to hospital as an emergency case with lower abdominal pain and discomfort in both loins. He was afebrile and mildly acidotic. Blood urea was 30 mg./100 ml. and haemoglobin 61%. A diagnosis of bilateral renal infection was made and he was treated with antibiotics. Intravenous pyelograms had been performed at regular intervals after his operation and remained normal until this admission, when both kidneys showed minimal dilatation of the pelvicaliceal systems consistent with the diagnosis of infection. Because of repeated severe attacks of infection, and while he was still passing blood occasionally per rectum, it was decided to convert his ureterosigmoidostomy to a ureteroileal conduit.

At operation a polypoid mass 5 by 5 by 3.5 cm. arising from colonic mucosa in the region of the left ureterocolic anastomosis was removed (see Fig.). Histologically the pedunculated cauliflower-shaped tumour showed irregular acini lined by pleomorphic hyperchromatic epithelium in both the polyp and its pedicle. The features were consistent with a diagnosis of adenocarcinoma.

Polypoid mass removed from Case 1. Diameter 5 cm. The probe has been passed through the ureterocolic anastomosis and marks the position of the ureteric "orifice."

CASE 2

This 19-year-old boy had his ureters transplanted into the sigmoid colon in 1951, at the age of 4 years, for incontinence secondary to an epispadias. He remained well until 1966, when he was

admitted to hospital as an emergency case with a large polyp prolapsing through the anus. This was reduced under a general anaesthetic. Subsequent sigmoidoscopy and a barium enema showed the tumour situated in the sigmoid colon 25 cm. from the anus. A series of intravenous pyelograms up to 1963 had demonstrated a normal upper renal tract; now, however, a pyelogram showed a hypertrophied right kidney, without evidence of obstruction, and a small left kidney with dilated calices and little function. He was mildly acidotic with a hyperchloraemia of 112 mEq/litre and blood urea of 40 mg./100 ml. The tumour was removed through a trans-abdominal colotomy from the region of the ureterocolic anastomosis. Histological examination of the cystic mucous polyp (diameter 5 cm.) showed areas where cell nuclei were hyperchromatic and displaced from their normal basal position. The possibility of malignancy could not be ruled out.

DISCUSSION

No aetiological agent has been clearly implicated in the development of these neoplasms. The chance occurrence of a spontaneous growth of the colon is unlikely because of the close proximity of all but two of the lesions reported in the literature to the transplanted ureteric "orifices," and the relative youth of the patients. Histologically two of these tumours were similar to those for which the operation was performed—namely, transitional-celled carcinomas of the bladder. The remainder consisted of 12 adenocarcinomas, three mucous-secreting adenomatous polyps, one transitional-celled carcinoma, and one scirrhous carcinoma. Twelve patients who developed a tumour in the colon after operation for some benign disorder such as bladder extrophy did so 10, 15, 15, 15, 15, 16, 17, 17, 30, 30, and 31 years later. Five patients whose ureters had been transplanted because of bladder malignancy developed growths of a different nature to the primary cancer 5, 7, 8, 9, and 9 years after the operation.

With improvements in the surgical technique of uretero-sigmoidostomy and in postoperative care these patients may anticipate a reasonably normal life-span. It would seem that a long-term survival brings with it the dangers of a complicating colonic carcinoma, and it is notable that 8 of the 19 patients were dead at the time their histories were reported in the literature. A review of case reports indicates certain warning symptoms and signs that were present in 15 of the 17 histories available for study. Upper urinary tract disease suggesting ureteric obstruction or reflux was detectable in 10. Large-bowel disorders were present in 11—chiefly alterations in bowel habit with evidence of obstruction in five and diarrhoea and tenesmus in others. Blood was passed per rectum in five.

These symptoms and signs are not especially remarkable in patients with a ureterosigmoid transplant, but their occurrence many years after the initial operation adds some significance. At this late stage most patients have a well-established routine of bowel action, and any change is quickly noted. Similarly, an unexpected alteration in the appearance of the kidneys on the routine follow-up intravenous pyelogram or the late development of a hydronephrosis must alert us to the need for radiographic examination of the large bowel and sigmoidoscopy. The presence of blood in the effluent should also be taken as an indication of possible neoplasia.

Urdaneta *et al.* (1966) have made a plea for routine follow-up proctoscopy and barium-enema examinations, but the practicality of performing these investigations regularly over many years is open to question. Clinical suspicion must remain the chief diagnostic weapon, followed by radiography, sigmoido-

scopy, and perhaps a willingness to convert these patients to ureteroileal conduit at the first sign of urinary tract trouble, when a carcinoma may be fortuitously discovered as in Case 1. Probably the ureteric stump and surrounding colonic mucosa should be removed at the time of this conversion, for Gillman (1964) described a case where an adenomatous polyp developed at the site of ureterocolic anastomosis seven years after the ureters had been transplanted into the colon, and six years after removal of the associated kidney.

We wish to thank Mr. R. K. Debenham, Mr. Victor S. Brookes, and Mr. G. H. Baines, under whose care these patients were

admitted, for permission to publish these reports, and Mr. Tom Dee for preparing the photograph.

Nail-gun Fatality

Brit. med. J., 1967, 4, 784

The rising incidence of industrial accidents in 1966 was pointed out in a leading article in the *British Medical Journal* (1967) which commented on the Annual Reports of the Chief Inspector of Factories (1967). The accidental death described below must surely be one of the more unusual kinds of industrial hazard.

CASE REPORT

A foreman in charge of a local construction project gave a demonstration to his men on how to handle the explosive cartridge hammer or gun and showed that, provided the muzzle was not placed against a solid object, firing would not occur when the trigger was pulled. The function of the gun is to fire nails into building materials such as wood in order that a firm attachment can be made to masonry or metal. The motive force in this particular instance was supplied by the explosive charge of a 0.22 cartridge. A little later one of the employees held the muzzle of the loaded gun against a rigid support but left the end of the barrel exposed, intending to fire a nail through chipboard held 6 ft. (1.8 m.) away by a workmate. The nail penetrated the chipboard and ricocheted into a young electrician as he was ascending the stairs from the floor below. He was hit in the chest, stumbled backwards down a few steps, and died in a short time.

NECROPSY REPORT

The body was that of a well-built young man with pink froth at the lips and blood on the clothes, face, and hands. The clothing was removed after photographs had been taken, and in the mid-clavicular line on the anterior chest wall just beneath the first left rib was a discoloured area 2 by 1 cm., in the centre of which was a circular hole 0.5 cm. in diameter. There was severe haemorrhage into the tissues of the root of the neck and also from the intercostal vessels of the first rib space. The neck bleeding originated from tributaries of the left innominate vein; the missile had also penetrated the innominate artery and then embedded into the parenchyma of the right upper lobe.

The missile was a nail 5.2 cm. long with a head 0.5 cm. in diameter. The direction of the nail's path was across the chest

from left to right with a posterior and slightly downwards tilt; the pointed end of the nail was the leading edge.

The pericardium was not involved; the heart valves were within normal limits and the coronary arteries were normal. There was 1 pint (570 ml.) of blood in the right pleural cavity and half this volume in the left sac. Bruising and local bleeding into lung tissue, particularly into the right upper lobe, were prominent features and vesicular emphysema was widespread. The trachea and the bronchi of the right lung contained blood and froth; the nail had cut into large pulmonary vessels and several bronchi. The stomach contained some swallowed blood, but the small and large intestines showed nothing of note; the liver and spleen were smaller than normal, but the adrenals, pancreas, kidneys, ureters, and bladder were within normal limits. There was no evidence of cerebral haemorrhage. Death was due to haemorrhage and mechanical obstruction to respiration.

COMMENT

The use of this relatively new tool is widespread in the building industry and will almost certainly increase; it is thus of vital importance to know how to handle it in absolute safety. At the inquest on this case there was a rider brought in which deplored the fact that the instructions issued by the manufacturers of the hammer had not been followed, and it was requested that the accident prevention officer should instruct all contractors using such mechanical devices to warn all their employees of its potential danger.

The workers involved in this incident were young men, and the Chief Inspector of Factories drew attention to the high accident rate in this group. Certainly the increase in fatal accidents by 12% in 1966 over the preceding year is of serious significance. There might even be a case for licensing the tool and limiting its use to workers specially trained in its operation.

I wish to thank the Bailiff of Jersey and H.M. Viscount, Mr. H. V. Benest, for permission to publish this case.

JOHN CRAGG, M.D., B.Sc.; D.P.H., DIP.BACT., M.C.PATH.,
Consultant Pathologist, General Hospital, Jersey.

Clinicopathological Conference

A Case of Congenital Heart Disease in Mother and Child

DEMONSTRATED AT THE ROYAL POSTGRADUATE MEDICAL SCHOOL

Clinical History

Dr. J. A. DAVIS: The patient (Case No. 298928, P.M. No. 11116) we are about to discuss was a male infant born on 30 December 1964. He was the child of the third pregnancy of a 25-year-old woman with a proved Fallot's tetralogy. The first pregnancy had ended in an abortion at 3 months; the second yielded a live infant who weighed only 1,420 g. at 37 weeks' gestation and died at the age of 30 hours following a hypoglycaemic fit. This pregnancy was uncomplicated but the mother was admitted to hospital for the last three months for rest. One month before delivery, at 33 weeks' gestation, an x-ray showed the baby to be the size of a normal 28-week foetus, and thereafter growth appeared to cease. At 37 weeks' gestation an elective Caesarean section was performed and the mother was delivered of a male infant weighing only 1,160 g. The placenta was also very small; the cord was shrivelled, and the baby had the appearance of an underweight-for-dates infant, the head being relatively large (H.C. 29 cm., H.C./B.W. ratio 25) though as regards central nervous system development he was assessed as of 32-34 weeks' gestational age. At 2 hours of age a glucose tolerance test was performed via umbilical vessel catheters. The fasting blood sugar was below 10 mg./100 ml. and returned rapidly to this level after rising to 63. The plasma growth hormone level at the depth of the hypoglycaemia was 50 μ mg./ml.

An injection of glucagon resulted in a small and brief rise of the blood sugar to 19 mg./100 ml. A solution of 7½% dextrose and 33½% fructose was given by infusion via a scalp vein at a rate of 2 ml./hour for 24 hours, and thereafter the blood glucose level was well maintained. The baby was asymptomatic and the E.E.G. pattern was normal for a baby of 32-34 weeks' gestation. During the performance of the glucose tolerance test it was noted that the blood in the umbilical artery was at low pressure (25 mm. Hg) and dark in colour (P_{O_2} 35 mm. in air; pH 7.28; no rise in P_{O_2} on increasing ambient oxygen).

On the second day a loud systolic murmur was heard down the left sternal edge and P_2 was noted to be very loud. Phonocardiography showed, in addition, an ejection click and a 4th sound. An electrocardiogram revealed excessive right ventricular hypertrophy; and there was clinical and x-ray evidence of cardiac enlargement though not of failure. Angiography was planned, but when the baby was 60 hours old the feet became white and pulseless and the arterial catheter had to be removed. The pulses in the feet then returned but the baby's condition steadily deteriorated and he died at 67 hours.

Clinical Diagnosis

- (1) Intrauterine malnutrition.
- (2) Neonatal hypoglycaemia.
- (3) Congenital heart disease (probably infantile coarctation).

Post-mortem Findings

Dr. M. J. R. DAWKINS*: The body was that of a male infant weighing 1,127 g. with a disproportionately large head for its size. Very little subcutaneous fat was present.

The main abnormalities were located in the *cardiovascular system*. A persistent left superior vena cava joining the coronary sinus was present. The aortic valve and the ascending aorta (circumference 8.5 mm.) were much smaller than the pulmonary valve and trunk (circumference 15 mm.). The ductus arteriosus was patent (Fig. 1) but showed intimal wrinkling and narrowing at the point of junction with the aorta. The isthmus of the aorta just above the entrance of the ductus showed a coarctation (circumference 3 mm.) (Fig. 1). The right atrium and tricuspid valve ring were widely dilated and there was a small defect (2 mm. diameter) (Fig. 2) high up on the interventricular septum underneath the septal cusp of the tricuspid valve, which was a little oedematous. The right ventricle was larger than normal (Fig. 3) and its wall was a little thickened (3 mm.). The interatrial septum and foramen ovale were normal and the left atrium appeared of normal size. The mitral valve and left ventricle were rather smaller than normal (left ventricle 1.5 mm.). Histologically the myocardium appeared normal.

The *lungs* showed areas of blotchy haemorrhage, and histological examination revealed focal intra-alveolar haemorrhage (Fig. 4) and generalized oedema. The intestines appeared normal and the *liver* (36 g.) was much smaller than normal, but histologically had the usual amount of extramedullary haemopoiesis. The ductus venosus was still patent. The *spleen* (3 g.) was normal, but the *thymus* (0.5 g.) was grossly atrophic and histological examination showed complete loss of the usual lymphoid cortex and only occasional Hassall's corpuscles (Figs. 5 and 6).

The *kidneys* (5 g. each) appeared normal (Fig. 7) and with no zone of glomerulogenesis, which suggests a gestation of at least 36 weeks. The glomeruli did not show the changes associated with cyanotic heart disease. The endocrine glands were normal apart from lipid depletion of the adrenal cortex. The *brain* (236 g.) was considerably larger than might be expected for the body weight and showed a mature convoluted pattern, consistent with the gestation of 37 weeks. Histological examination (basal ganglia, four areas of cortex and white matter, medulla and cerebellum) showed no abnormality and no evidence of the characteristic Purkinje cell changes associated with hypoglycaemia.

The *placenta* (270 g.) was much smaller than normal, and on the foetal surface the chorionic plate did not reach the placental edge (placenta extrachorialis). Outside the chorionic plate was a thick band of fibrin (Fig. 8), which in places appeared as laminated blood clot. Histological examination revealed normal villi in the underlying placenta with no evidence of dead villi in the ring of fibrin. Placental bed biopsies taken at the time of caesarean section and processed by Dr. Brosens

* Dr. Dawkins died on 27 June 1965.

showed diffuse infiltration of decidual stromal cells and giant cells with lipid. This type of infiltration has been found previously in association with prolonged pregnancy and hypertension and is attributed to local hypoxia.

Pathological Diagnosis

- (1) Congenital heart disease:
 - (a) Hypoplasia of ascending aorta and arch, with pre-ductal coarctation.
 - (b) Ventricular septal defect.
 - (c) Patent ductus arteriosus (closing).
 - (d) Persistent left superior vena cava.
- (2) Pulmonary oedema and haemorrhage.
- (3) Intrauterine growth retardation.
- (4) Placenta extrachorialis with fibrin deposition.

Discussion

Dr. DAVIS: There are a number of points worth drawing attention to here. First, Fig. 9 shows the relationship of birth weight to gestational age in babies born to mothers with cyanotic congenital heart disease.¹⁻¹² The line shows the relation of mean birth weight to gestational age for English children. Every single baby born to a mother with Fallot's tetralogy is below the expected weight line and most far below it. Some of these women in fact were subjected to operation before pregnancy; others fell pregnant with the uncorrected condition.

FIG. 9.—Birth weight plotted against gestational age in babies born to mothers with cyanotic congenital heart disease, with the mean for British babies. Figures from the literature; mean from perinatal mortality survey.

If one compares these figures with the birth weights of babies born to mothers with other forms of heart disease there is a very great contrast. Coarctation is shown in the Figure just as an example, but indeed in every other form of heart disease except cyanotic congenital heart disease the birth weights of the babies are normal for their gestational age. So there is something about the mother having cyanotic congenital heart disease which interferes with the growth of the baby in utero, whereas being in heart failure with some other condition apparently does not.

Hypoglycaemia

Then just a comment on our treatment of hypoglycaemia. We were in fact able to measure certain hormone levels in this

baby at the nadir of his hypoglycaemia. His growth hormone level was 50 $\mu\text{mg./ml.}$, which is about a normal level for a baby of that age but not a very spectacular response to a considerable degree of hypoglycaemia where levels as high as 250 $\mu\text{mg./ml.}$ have been described.¹³ His blood cortisol levels were also high, between 83 and 64 $\mu\text{g./100 ml.}$, but it is not yet clear what the response of a baby should be in these circumstances. Some time ago we successfully treated identical twins who were slightly hypoglycaemic; by giving prednisone to the more hypoglycaemic twin we were able to raise its blood glucose level, whereas in the other twin who was not given prednisone there was no such rise. The rise in blood glucose was associated with a rise in blood urea indicating that we had stimulated glucogenesis.

In the case under discussion we do not know whether it was feeding the baby—which does not usually have much influence on established hypoglycaemia—or the intravenous drip, or the administration of glucagon and prednisone which in fact rescued it from its hypoglycaemia. It is worth mentioning that the brain of the baby's sibling at death showed fairly gross lesions, which Dr. Sabina Strich has shown to be characteristic of hypoglycaemia, and that no such lesions were present in the brain of this baby. The normal level of blood glucose in healthy premature babies at this sort of birth weight varies over a wide range. They may have a low birth weight because they were born early or because they suffered from intrauterine malnutrition, and this is responsible for a wide scatter in the normal levels. Levels nearly as low as that found in this case are compatible with perfectly good health. Our experience has been that only when the level falls below 20 mg./100 ml. does the baby become symptomatic and that symptoms do not usually appear unless the level is below 10 mg./100 ml. There is some evidence that the brain can use other substrates as well as glucose for its metabolism in the first days of life.¹⁴ In this particular case we were able to predict the onset of hypoglycaemia and to treat it adequately, and it was sad then to find that the baby had severe congenital heart disease. There is, I believe, some unpublished evidence that the incidence of congenital heart disease is in fact very much higher in the children of mothers with Fallot's tetralogy or other forms of cyanotic congenital heart disease than it is in the general population. Of course, there is about a 3% incidence anyway in the children of women with congenital heart disease but the incidence when they have cyanotic congenital heart disease is considerably higher. So this baby's heart disease was probably environmentally determined; and this suggestion is supported by the fact that the baby had a different form of heart disease to its mother's. On the other hand, this baby's first cousin, born to a perfectly normal mother, died in the immediate neonatal period with a truncus arteriosus.

Effects of Heart Disease on Pregnancies

Professor J. F. GOODWIN: Dr. Oakley, I believe you have some views on cyanotic heart disease in pregnancy and the effects on the baby.

Dr. CELIA OAKLEY: A survey was carried out at Johns Hopkins Hospital by Dr. Catherine Neill on all patients who had attended the cardiac clinic with congenital heart disease and who had reached or passed the age of 18 when the survey was started.¹² Over 700 patients answered a questionnaire and 235 (159 families and 76 males) had had children. There had been 508 pregnancies with a 1.8% incidence of congenital heart disease in the children (roughly six times the expected). The outcome of pregnancy had been near to normal in the acyanotic patients and they didn't have a greatly abnormal incidence of miscarriages, other foetal abnormalities, or stillbirths compared with the general population. Dr. Neill found on the other hand that the outcome of pregnancy in the cyanotic mothers (but not in cyanotic fathers) was very different; they had an

0 5 10 15
CENTIMETRES

exceedingly high rate of foetal loss. There were 110 pregnancies in 54 cyanotic mothers and Dr. Neill's figures which I will quote to you are based on these numbers. The rate of abortion was about six times the rate in the general population. This seemed to be so high that it was thought wise to try to break it down. The results were very interesting. In patients whose haematocrit was between 51 and 65% (moderate cyanosis) the miscarriage rate was over 60%. When the haematocrit was over 65% (severe cyanosis) the incidence of spontaneous miscarriage was over 80%. So that the cyanotic woman has a greatly reduced chance of bearing a live child.

The birth weights of these infants were low—they were low because the infants were born prematurely and the infants were also very small for their gestational age. The placentae on the whole were large and contained infarcts, but if infarction was extensive then the placental weight was low. These were children who had been subjected to hypoxia for a long time; a survey carried out in Peru at high altitude also showed that the average birth weights were low and the average placental weights were high. The average birth weights of infants born to the cyanotic mothers was only 5½ lb. (2.5 kg.). As it might be suggested that these low birth weights in the cyanotic adults were genetically determined, the children of cyanotic fathers married to normal mothers were used as controls, and the mean birth weight of the children born was found to be about 7½ lb. (3.4 kg.) (normal). The incidence of congenital heart disease in the children of cyanotic mothers and fathers (most of them had Fallot's tetralogy) was the same as the incidence of congenital heart disease in the infants born to parents with acyanotic conditions. So apparently the higher incidence of foetal death, stillbirth, and prematurity was due to an environmental rather than to a genetic cause. This of course is a generalization and there are some families who have high incidence of congenital heart disease in them where several siblings usually have a similar condition. This has a very important bearing on the mother of the child who is being discussed now. She is desperately anxious to have children and we want to know whether to advise her to have another try or to adopt children. Personally, I would advise her (if she survives the correction operation which she has just had) to have another pregnancy. Her chance, having become acyanotic, of having a healthy child should be very much better. The risk she will run of having a child with congenital heart disease is only about three times that of the general population, unless, as is somewhat suspect, she is one of those unfortunate cases in whom there is a definite genetic risk in the family.

Family History

Professor GOODWIN: It is worth enlarging on the mother's disease. We have known her for many years, for we first saw her as a child. She was investigated by Dr. Maurice McGregor and Dr. Mounsey in 1948-9. She had the tetralogy of Fallot with minimal cyanosis; and you will recall that the main factor which determines cyanosis in the tetralogy is the difference between the resistance to the blood flow offered by the right ventricular outflow tract and the systemic resistance. Thus patients with only moderate pulmonary stenosis may be almost acyanotic at rest but on exercise systemic resistance falls, peripheral vasodilatation occurs, the right ventricular inflow increases, and shunting of blood from the right ventricle to aorta occurs and cyanosis follows. Because she was only minimally cyanotic she was not offered a Blalock operation, which was current at that time, and indeed operation was advised against until such time as complete correction became available. Subsequent catheterization revealed an additional atrial communication and operation was advised. As Dr. Oakley says she has now had this operation.

This history does not bear on the present situation except that it is one further instance of a similar lesion in the child,

who had a patent foramen ovale as well as an atrial septal defect and ventricular septal defect. I suppose that acyanotic patients with the tetralogy are more likely to have a viable child than those who are frankly cyanosed. During pregnancy peripheral vasodilatation and cardiac output increase and they become more cyanosed. Reduced oxygen saturation in the blood supply to the foetus must play a part in affecting the foetus, and I think this must be the reason for the persistently low birth weights.

It is doubtful whether one should advise this patient to have another pregnancy. There have already been two disasters and there is a relative who had an infant with congenital heart disease. There are clearly two factors operating to compromise the baby's chance here.

Dr. OAKLEY: There was one cousin whose baby was abnormal, but it is not known whether this was due to a genetic cause and, therefore, relevant or whether it was environmental. I believe that the previous baby, who died of hypoglycaemia, had a normal heart. Advice should not be weighted too heavily just because of one cousin.

Bed Rest

Could I make one more comment? The mother of this baby was advised to spend a large part of her pregnancy in bed for a very good reason; it was not because of any concern for the mother herself, for we were fully confident that she would weather the pregnancy—she was a little blue and breathless without any undue trouble; but it was in an effort to keep the environment of the baby at as high an oxygen tension as possible. All these patients with Fallot's tetralogy change their arterial oxygen saturation very widely—they may be almost completely saturated at rest, but with a fall in systemic resistance on effort when the cardiac output goes up the oxygen saturation may fall by 30% or even further.

Professor J. P. M. TIZARD: Were any actual measurements made of arterial oxygen saturation in this patient during her pregnancy?

Professor GOODWIN: I don't think so.

Professor TIZARD: Was there a margin of safety, I wonder? In a normal woman the uterine arterial oxygen tension is about 90 mm. Hg, but by the time the oxygen reaches the foetus in the umbilical vein the tension is somewhere in the 40s (this is in normal pregnancy). This fall in tension has been shown recently by Geoffrey Dawes¹⁶ not to be due to any diffusion barrier but simply to what is used up in placenta tissue. If there is a marked drop in oxygen tension over a long period it is difficult to imagine how the foetus can survive.

Can I ask one question about the heart? The photograph of this baby showed that the lower half of his body was paler—why should the ductus close at all under these circumstances?

Effect on Ductus

Professor GOODWIN: I don't know. I agree that teleologically it ought to remain open. One might expect that in the severe tetralogy the ductus would be more likely to remain open, and there are situations—extreme forms of the tetralogy amounting to pulmonary atresia, where the patent ductus has remained patent as the major source of blood supply to the lungs. Most patients with the tetralogy don't have a patent ductus, however.

Professor TIZARD: But I would expect the oxygen tension in the blood reaching the ductus would be high enough to promote normal closure. I don't know whether Dr. Davis perhaps knows the limits of this.

Dr. DAVIS: I don't, but I suggest that we may have made this ductus close by putting this baby in higher than normal

environmental oxygen concentrations thinking that this action was therapeutic. We found a very low oxygen tension in the umbilical arterial blood—on the edge of a cliff as regards the dissociation curve—and we thought we had better try to raise it. This may be precisely what caused the final catastrophe.

Professor TIZARD: Successfully raising the venous blood tension?

Dr. DAVIS: Yes.

Professor GOODWIN: I wonder how likely it is that a low oxygen environment may be closely concerned with this type of developmental anomaly? In children born at high altitudes congenital heart disease is commoner than in those born at sea level; but it is usually patency of the ductus, though other forms do occur. Have you any views on the likelihood in this case of the congenital heart disease being related to the low oxygen tension?

Dr. DAWKINS: I have no views that I can support. Attempts have been made to investigate this problem in animals, but such experiments usually result in loss of the foetus or no particular damage. It depends on what might have happened over one day early on in the pregnancy.

Professor GOODWIN: It could have been very early in pregnancy.

Dr. DAWKINS: Before she was put to bed.

Professor GOODWIN: Also, perhaps, before she was really substantially cyanosed, unless she was taking a lot of exercise at the time.

Little is known with certainty about the causes of ventricular septal defect except that infection in the mother with rubella in early pregnancy is a cause. Chromosomal disorders may be associated with congenital heart disease. Otherwise there are merely suggestions such as consanguinity of parents and the difference between mother's age and father's age being greater than the average. These were factors in 180 cases of ventricular septal defect studied by Dr. M. Campbell and myself.¹⁶ There are some strange seasonal variations in the incidence of coarctation of the aorta and patent ductus which Polani and Campbell¹⁷ have described. Girls with patent ductus are born more frequently from August to October and less frequently from December to March. Boys with coarctation are born more frequently from December to July. This is even more odd because it doesn't even fit with the seasonal incidence of rubella.

Of course thalidomide and excessive irradiation are well known teratogenic poisons which may produce congenital defects.

Professor TIZARD: Genetic factors may play a partial and unimportant role in many forms of congenital disease but simple modes of inheritance are rare. Endocardial fibroelastosis is probably inherited as an autosomal recessive.

Professor GOODWIN: There is a possible suggestion that interference with the lymphatic flow is relevant. Endocardial fibrosis and subendocardial haemorrhage have been produced in animals by Miller and colleagues¹⁸ but whether this is related to human endocardial fibroelastosis I have no idea at all. Anoxia has also been put forward as a theory.

Obstetric Problems

Mr. G. DIXON: These patients with cyanotic heart disease, from our point of view, are rare examples of chronic placental insufficiency. We see a much more acute form in maternal hypertension and postmaturity and an intermediate form in the "small-for-dates" babies. Clinical assessment of insufficiency of the placenta is terribly difficult and the methods in use are still crude. Here, in an extreme form, one had a uterus which did just correspond in size to the gestational age for most of the pregnancy; but it is interesting that during the first half of pregnancy her uterus grew perfectly normally and

then apparently stopped. The methods we use are, as I say, terribly crude. The lady had put on 9 lb. (4 kg.) in weight during her pregnancy and this was indicative of the failure of the foetus to develop. We also measure the abdominal girth because while the girth is increasing we presume that the placenta is working well enough to allow the baby to grow; but there are many sources of error. There has been so much obstetrical erudition this morning that there is not much more to say, but I would like to add to Dr. Oakley's point about the oxygen saturation increasing when the patient rests by saying that presumably the intervillous blood flow increases, though we have as yet no real evidence of it.

Professor GOODWIN: The management of this mother was very difficult, and looking back we may possibly have made the wrong decision. She had been accepted for radical correction of the tetralogy and then became pregnant. This was her second child, she had lost the first, and one's impulse was to say, "Let us get on with the operation and hope the child survives; at least we shall have dealt with her heart lesion, corrected the cyanosis, and she can become pregnant again and all will be well."

Dr. Oakley and I had long discussions with the surgeons and obstetricians about what would be the best thing to do. We felt finally that we should not incur the risk to her and the baby of doing the operation during pregnancy. I don't know of any figures of pregnant patients operated on with cardio-pulmonary bypass, though there is plenty of information on pregnant patients operated on for mitral valvotomy and that as a rule does not disturb the foetus in the very least. But under cardio-pulmonary bypass things might be very different. Has anyone any information on this point?

Dr. DAVIS: Yes. Such operations have been done during pregnancy and I think one of the babies survived though the others were lost.

Professor GOODWIN: So the chances presumably would be against the survival of the baby. It is worth remembering that if you advise an abortion on the grounds of the mother's health you decide inevitably to sacrifice the baby, whereas if you advise an operation on the mother then you have a reasonable chance of saving both the baby and the mother. If we were faced with this situation again we should ask the cardiac surgeons to get on with the operation quickly. I think we would have lost the baby but we would have saved the mother a lot of distress—though the risk to her of operating during her pregnancy might have been greater.

Dr. DAVIS: I would like to stress that we needn't have lost the first baby, which died of a treatable condition, and that we expected this to be the only real problem in the second one.

Professor GOODWIN: We did not at that time know about the cousin. Dr. Mounsey, you have something to add?

Clinical Diagnosis

Dr. J. P. D. MOUNSEY: Initially there was some disagreement as to what the congenital lesion in this baby was likely to be. May I ask what the points were on which a correct diagnosis of coarctation with a ductus and a ventricular septal defect was made? I presume that the reason for diagnosing coarctation was the time of onset of deterioration of the baby, and the evidence of poor circulation to the lower part of the body, with reduced blood pressure and PaO_2 . The reason for the diagnosis of ventricular septal defect, I presume, was the presence of this systolic murmur, which was perhaps loud and harsh. I left out the E.C.G. There is more right heart hypertrophy than you would expect in a baby of this age.

Dr. DAVIS: What made us suspect coarctation was the low blood pressure in the umbilical artery. We had a direct reading of it and it was quite outside what we normally expect to find. This, associated with a very low oxygen tension, in a baby who

was plainly not in respiratory difficulties or in heart failure, very much suggested that the upper part of the body was being supplied with adequately oxygenated blood though we knew the lower part was not. Those two findings are not compatible with any other diagnosis. Why we rejected the diagnosis up to a point was that we thought the catheter may have been so placed as not to give us true blood pressure readings. The PO_2 did in fact rise during the period of observation. Thus there was every reason to believe that there was a coarctation, but the other findings could not be explained by that alone, and the murmur suggested that the baby had a ventricular septal defect—in fact, it was characteristic of that abnormality. That was the way we looked at it.

Professor GOODWIN: I thought it very likely that if there was any cardiac lesion it would be the same as the mother's. So I thought a ventricular septal defect was likely on those grounds. Now we know that a proportion of patients with the tetralogy of Fallot in childhood or later life may start with a ventricular septal defect only and then develop progressive infundibular hypertrophy to such a degree that the left-right shunt reverses, leading to the tetralogy. A ventricular septal defect would then be the sort of basic anomaly that one would expect the child to have if the mother had the tetralogy of Fallot or a ventricular septal defect without pulmonary stenosis. The cardiogram (I think one could have been a little cleverer about it) does show, as Dr. Davis pointed out, extreme right heart enlargement. This is the sort of tracing seen in babies born with pulmonary atresia and intact ventricular septum, or with, as this child had, the hypoplastic left heart syndrome with most of the work of the heart being done by the right side. The right ventricular hypertrophy is too great for ventricular septal defect alone, and perhaps too strong for an infant born with the tetralogy with established pulmonary stenosis. The loud second heart sound we thought might be the result of pulmonary hypertension.

Intrauterine Malnutrition

Professor TIZARD: Could I change the subject from the heart for a moment to say what an impressive lot of clinical, biochemical, and pathological evidence there is here in favour of the baby being a case of intrauterine malnutrition? Until a few years ago if a baby had been born at 37 weeks weighing 1,100 g. the conclusion would be drawn that the pregnancy was really very much shorter and that a mistake had been made about the date of gestation. Of course this is not only a matter of theoretical but also of great practical importance when it comes to looking after these babies, because the small ones born early present very different problems from the babies with normal gestation and intrauterine malnutrition. Could I just ask Dr. Dawkins a question with regard to this very small thymus? Is this a usual finding in intrauterine malnutrition and does this correlate with any immunological defect in the developing foetus?

Dr. DAWKINS: Certainly it is a usual finding in babies with intrauterine malnutrition. It is interesting that in this very

rare cause of intrauterine malnutrition you get the same effect on the foetus as with the more common causes of malnutrition like hypertension. There is no doubt that the small babies don't grow so well in the postnatal period and they have more infection in the first year of life, and there is some evidence that the immunological competence may be reduced in these babies. Of course it is well known that thymectomy in newborn animals produces failure of growth and this is shown to be due to recurrent infection.¹⁹ The thymus is responsible for the development of the lymphoid system throughout the body and removal of the thymus prevents the development of lymphoid follicles.

Dr. DAVIS: Could I make a last observation with regard to the blood chemistry in relation to the heart? With a PO_2 of that order I think you would expect high blood lactate levels, but they did not in fact rise until a few hours before death. This led us to believe that part of the body at least was being properly supplied with oxygen at normal tension. I would also like to point out that all those biochemical estimations were done on a total of 10 ml. of blood, which is quite a small proportion of the baby's total blood volume and a loss that babies can tolerate quite easily.

Professor GOODWIN: In conclusion, then, pregnancy in cyanotic heart disease is difficult and hazardous for mother and foetus, the chances of a successful pregnancy are small, and thus correction of the lesion is to be advised before pregnancy when possible.

We are grateful to Professor J. P. Shillingford and Dr. E. D. Williams for assistance in preparing this report, and to Mr. W. Brackenbury for the photomicrographs.

Current Practice

DISEASE OF THE DIGESTIVE SYSTEM

Surgical Treatment of Upper Alimentary Bleeding

H. L. DUTHIE,* M.D., CH.M., F.R.C.S.

The place of surgery in the management of patients with bleeding into the stomach or duodenum is largely governed by two aspects of the haemorrhage: the total volume of blood lost and the rate of bleeding.

Other factors which are of importance are the cause of the bleeding and the age of the patient. Severe bleeding is one of the most demanding emergencies, and the decision may need to be made rapidly and the operation performed with dispatch. Fortunately most upper alimentary bleeding settles with conservative management and in only a minority of cases does immediate operation have to be considered. However, in all cases the question of surgery to prevent recurrence of the bleeding ought to be considered.

Co-operation

The approach to the diagnosis and treatment of upper gastrointestinal haemorrhage should be co-operative between physician and surgeon. In most centres such cases are admitted to medical units, but in the others to surgical units. The locus of the patient does not matter: the joint consultation is all-important. This joint action is too well established throughout Britain to need much emphasis; the surgeon benefits from seeing patients who do not require surgical treatment, the physician benefits from having earlier recourse to surgical assistance, and, best of all, the patient benefits by having the appropriate treatment at the appropriate time.

* Professor of Surgery, University of Sheffield.

Indications for Surgery

In the overall management of upper gastrointestinal bleeding the priorities may be stated as (1) life saving; (2) diagnosis; (3) definitive treatment. Surgical therapy may be called for in step one, when the endeavour is to accomplish all three objectives, or it may be left to stage three. Definitive treatment is to be preferred where it is compatible with the progress of the patient. The rapidity of the blood loss is the main factor indicating the correct time to operate (Table I).

Bleeding Threatening Life

When the bleeding threatens the life of the patient, despite adequate transfusion, operation must be done even though the diagnosis may not be known, provided that haemorrhagic disorders have been excluded. In some cases a preoperative diagnosis will have been established by a typical history of peptic ulcer, or of ingestion of aspirin, or of hepatic cirrhosis with portal hypertension, and in the last instance the physical examination will usually elicit signs of hepatic failure and the spleen will be palpable. A working diagnosis may be further buttressed by previous radiological findings. However, there may be no time to proceed to further diagnostic measures. Fortunately a bleed as demanding as this is uncommon and some time can usually be obtained for at least a radiographic study in the ward or for an endoscopic examination.

What does the surgeon do at operation? He first attempts to confirm or establish the source of the bleeding, then to stop

TABLE I.—Place of Surgical Treatment in the Management of Bleeding from the Gastrointestinal Tract

it, and finally to attempt to prevent its recurrence. Chronic duodenal ulceration is frequently detectable by inspection of the outside of the duodenum, but the duodenum may have to be opened to be quite sure of the presence of a small penetrating ulcer on the posterior wall. Gastric ulcers may be more difficult to detect and the stomach may have to be opened widely to locate the lesion, especially if it is an acute erosion. Another technique to assist in the location of the bleeding point at operation is to insert a sigmoidoscope through a small hole in the stomach. By inflating the stomach the mucosa may be examined, but the presence of blood and blood clot makes this difficult. I prefer opening the stomach and everting the lining, though blood clot may again make visualization tedious, and the mucosal folds must be carefully separated to make sure that a small lesion has not been overlooked. Portal hypertension is

indices of persistence of bleeding usually are the continued presence of occult blood in the stools and a consistently falling level of haemoglobin in the blood. The bleeding is then more an additional indication for surgery to treat the underlying cause rather than an absolute indication in itself.

Age

It is generally held that patients over the age of 45 to 50 should be considered more readily than younger patients for surgical treatment of bleeding, since vessels affected by the inevitable arteriosclerotic changes of age will be less likely to contract to assist in the arrest of the haemorrhage. However, in the case of the chronic duodenal ulcer this is hardly valid. No matter the age of the patient, the vessels in the base of the

FIG. 1

FIG. 2

FIG. 3

usually diagnosed preoperatively, but, if not, the presence of venous collaterals in the abdominal wall is indicated by the excessive bleeding encountered when making the incision. Once the abdominal cavity has been opened the enlarged spleen can be felt and the cirrhotic liver can be seen together with the distended intra-abdominal veins.

When the source of bleeding has been found it must be stopped at once by direct pressure, by oversewing, or by applying a clamp, and the transfusion allowed to continue for a few minutes to improve the patient's general condition before proceeding with the operation. The choice of procedure will be discussed later.

Severe Bleeding—No Threat to Life with Transfusion

In this group the severity of the bleeding ranges from that in which the blood pressure can be maintained only with transfusion to the patient in whom the bleeding stops quickly and the transfusion replaces the lost volume. The value of time gained by transfusion is that the patient can get into a better condition to undergo surgery or to undergo investigation. History, physical examination, then immediate radiology, assessment of gastric acidity, and immediate gastroscopy combined can give a positive diagnosis in over four-fifths of patients. This is a great advantage to the surgeon, but no time must be lost attempting to make the diagnosis. If the patient's condition deteriorates, as seen by further fall in blood pressure, rise in pulse rate, and fresh blood in the gastric aspirate, immediate surgery is indicated. In this group recurrent haemorrhage is a frequent indication for operation, and usually after the diagnosis has been made.

Moderate Bleeding

When the amount of blood lost does not cause a decrease in blood pressure the problem is much less acute, and the

ulcer undergo periarteritis and become thickened. With this in mind, operation should not be postponed too long simply because the patient is in his twenties or thirties.

Cause of Bleeding

Both the indications for operation and the type of procedure will be influenced by the source of bleeding. The four most common causes in Britain are chronic peptic ulcer, acute ulceration, gastric cancer, and oesophageal varices.

Chronic Peptic Ulcer.—The bleeding is usually from a duodenal ulcer. Apart from the severity of the haemorrhage, the previous history of the patient will influence the decision to operate, especially if his symptoms are escaping from medical control. The general principle with this and any other cause of bleeding should be to treat surgically any patient who continues to bleed, either briskly—when an emergency procedure would be required—or more slowly over two or three days, when a more leisurely approach may be made. The other type of bleeding which leads to operation is recurrent bleeding—again the speed with which treatment is required depends upon the rate of the bleeding. This is assessed by the response of the pulse rate, which rises much earlier than blood pressure falls, the presence of fresh blood in the gastric aspirate (gastric intubation should be routine in these cases), and the clinical response to blood transfusion.

At this point it is well to mention another circumstance which occasionally has to be considered when the patient continues to bleed slowly but requires further transfusion of blood. If blood of the patient's group is in short supply, especially if of a rare group, a decision has to be made when three to four pints (units) are still available. If the bleeding seems to be stopped it may be safe to delay, but if any doubt exists this is a strong indication for operation while there is enough blood to cover it.

TABLE II.—Operations for Upper Gastrointestinal Bleeding

Procedure	Indications	Advantages	Drawbacks	Present Status
Partial gastrectomy	Duodenal ulcer. Gastric ulcer. Acute erosions. Gastric cancer	Removal of source of bleeding and reduced likelihood of re-bleed. Allows a larger gastric remnant	Severity of procedure. Still has some rebleeding. Small stomach symptoms	Most common procedure
Vagotomy with hemigastrectomy	Duodenal ulcer. Gastric ulcer. Acute erosions	More minor operation. No loss of gastric reservoir	As above except fewer symptoms from small remnant. Post-vagotomy diarrhoea	Gaining popularity as a compromise between 1 and 3
Vagotomy and pyloroplasty with oversewing lesion	Duodenal ulcer. Gastric ulcer. Acute erosions		Risk of rebleed. Post-vagotomy diarrhoea	Used when lesion is small (1 cm. or less) but still to find favour with majority

Thus in general a patient with a long history of proved peptic ulcer disease will come to surgery earlier than when the diagnosis is in doubt or when an acute ulcer is suspected.

Choice of Surgical Procedure.—The aim of the operation (Table II) is to stop the bleeding and to prevent its recurrence. Unfortunately none of the procedures available can guarantee to do both in all cases, but all achieve both aims in the majority of patients. The reasons for any choice of a particular operative technique are always multiple and are compounded of the risks involved to life and in terms of later morbidity, together with the efficacy in fulfilling the aims. In the surgical treatment of chronic peptic ulceration until 10–20 years ago the favoured operation was partial gastrectomy. This is now being displaced by vagotomy and a drainage procedure. A similar trend has occurred when treating bleeding ulcers, but it has been much less marked. Most surgeons still prefer to resect the ulcer, and so partial gastrectomy is the commonest operation (Fig. 1). Some surgeons who are more impressed by the reported incidence of undesirable side-effects of gastric resection prefer to resect less of the stomach (hemigastrectomy or antrectomy) and to combine this with a vagotomy to avoid recurrent ulceration (Fig. 2). My own preference is to control the bleeding by local excision of the ulcer if it is gastric or anterior duodenal or to oversew the bleeding point if the ulcer is about 1 cm. in diameter or less; then to attempt to prevent recurrence by performing a vagotomy and pyloroplasty (Fig. 3). It seems rational to denervate only the stomach and preserve the branches of the vagus to the liver, pancreas, and small bowel—a selective vagotomy. However, it takes longer to perform a selective vagotomy than to divide the main vagal trunks as they pass through the diaphragm, and in an emergency the latter procedure being more expeditious may on occasion be preferred.

Apart from the drawbacks of the "dumping" syndromes after gastrectomy and changes in bowel habit after vagotomy, the main untoward sequela of these operations when used in the treatment of haemorrhage is that they fail in 5% to 15% of cases—that is, bleeding recurs in these patients. The bleeding is usually more minor than the acute incident leading to the first operation. Opinions differ on the risks of this occurring with the various operations, but the general trend from the literature is shown in Table III. The further loss of blood

adopted. The aim should be to avoid surgery if this is at all reasonable, since the lesion in many cases is reversible. If the effects of the initial bleeding can be controlled until it stops the patient avoids an operation. In this group especially the use of gastric hypothermia seems to be most rational. The indications for operation are still persistent or recurrent bleeding, but the tendency is to postpone the operation longer than with the chronic ulcer patients. The choice of operation is the same as for chronic ulcer. There is a strong case for the use of vagotomy and a drainage procedure; this avoids the possibility of having to remove almost all the stomach if widespread lesions have all to be resected.

Gastric Cancer.—Gastric cancer is not very commonly the basis of a large haemorrhage, and usually the decision to operate can be made at relative leisure. The resection of the growth is the only practicable procedure: this may be a palliative excision only, but it will serve to arrest the haemorrhage.

Oesophageal Varices.—Massive bleeding often arises from oesophageal varices. This is another condition in which efforts are made to do without acute surgical intervention, particularly since the postoperative mortality and morbidity are high. The death rate from bleeding oesophageal varices is the highest of these four common causes of bleeding from the upper gastrointestinal tract. Management of the condition will be discussed in a separate article in this series.

Summary

The surgeon's role in the acute management of bleeding from the upper alimentary canal is to act when bleeding threatens life by its persistence or its recurrence. He may be called upon to make the diagnosis at operation and to proceed to control the bleeding. More usually the bleeding is less catastrophic and more time is available; the diagnosis has been made before operation and the control of the bleeding is the object of surgery. Partial gastrectomy is still the procedure most commonly performed for bleeding from gastric cancer or peptic ulceration, although direct control of the bleeding point along with vagotomy and pyloroplasty is also being used. Early joint consultation between physician and surgeon is the basis of sound management of upper gastrointestinal haemorrhage.

TABLE III.—Incidence of Further Bleeding After Partial Gastrectomy or Vagotomy and Pyloroplasty

Operation for Bleeding Ulcer	Number	Further Bleeding
Partial gastrectomy	167	12 (7.2%)
Vagotomy and pyloroplasty	142	9 (6.3%)

may be from the original ulcer if it was not removed, from the region of the stoma, from undetected lesions, or from recurrent ulceration. Though the surgeon succeeds in securing a definitive cure in the majority of patients, this worrying minority remains.

Acute Ulceration.—Whether the acute ulcer is peptic in the stomach or duodenum, or due to aspirin ingestion in the stomach, or is due to repeated vomiting tearing the mucosa at the cardia, a much more conservative approach should be

ANY QUESTIONS?

We publish below a selection of questions and answers of general interest.

Lithium in Schizophrenia

Q.—What, if any, is the effect of lithium salts in patients with schizophrenia, and have there been any trials of the use of lithium salts in the treatment of this disease?

A.—There is no unequivocal evidence that lithium salts have a beneficial effect in the treatment of schizophrenia, and a review of the literature does not indicate that any formal trial into the use of lithium salts in this disease has been carried out.

In a series of 28 papers recently reviewed concerning lithium therapy in other than affective disorders there is reference to schizophrenic patients within whole groups of patients suffering from other diseases, and for this reason it is difficult to interpret the claims made by some workers. Treatment responses even among these groups are classified by terms that have not been defined, making it even more problematical what the outcome has been.

The original work done by Rice¹ in Britain described the results of lithium therapy in 12 patients suffering from schizophrenia, and of these one improved but remained in hospital and one improved sufficiently to be discharged. Both of these patients exhibited aggressive behaviour in association with delusional thought content. In contrast with this group, nine patients who were suffering from a schizo-affective psychosis were also studied, and of these seven improved sufficiently to leave hospital. Annell² described a single adolescent patient with periodic catatonia in whom she found that lithium controlled the psychotic episodes.

Clinical impressions suggest that lithium can have a favourable effect in recurrent schizo-affective psychoses. Sir Aubrey Lewis³ has pointed out that it is in this type of psychosis (i.e., with affective symptoms) that the natural prognosis is more favourable, and for this reason it cannot be said that there is satisfactory evidence that lithium has been found to be of benefit in schizophrenia, though "blind trials" may yield further information.

Intermittent Uniocular Diplopia

Q.—What might be the causes of intermittent diplopia in one eye in an otherwise healthy male aged 38?

A.—Uniocular diplopia is usually considered to be rare and caused only by such conditions as partial dislocation of the lens and retinal detachment. However, a type of uniocular diplopia can be demonstrated in a high proportion of otherwise normal subjects under certain conditions.^{1,2} It is best seen when viewing a horizontal white target against a dark background—for example, a fluorescent street lighting or neon signs at

night. The second image is displaced vertically by about 5 minutes of arc and is fainter than the primary image. The doubling is probably caused by the upper part of the lens acting as a weak prism, base down, the base of the prism crossing the upper part of the pupil.

Little attention has been paid to this phenomenon by ophthalmologists, and the symptom is dismissed as being due to astigmatism. Correction of any refractive error reduces the effect by improving the definition of the primary image. The second image is still present, however. Constriction of the pupil or viewing through a pinhole abolishes the diplopia but is not a practical solution. Explanation and reassurance are usually all that is required.

Wounds from Galvanized Wire

Q.—Is there any evidence to support the belief in the wire-rope industry that wounds caused by galvanized wire become infected more often than those caused by other types of wire?

A.—No direct evidence on this point is known. A similar belief was formerly held about injuries from copper, but when this was checked in a comparative study of "swarf" injuries due to different metals no extra incidence of sepsis was found.

Zinc is not very toxic when applied locally. A 1% solution of zinc sulphate, for instance, has been used in eye drops, and a 4% solution for treatment of skin lesions. Antiseptic properties are claimed for these preparations, so it seems unlikely that the zinc present on galvanized wire would itself increase the risk of sepsis. A recent study further claimed to show improved wound healing when zinc sulphate was given orally.¹

If enough comparable wounds caused by wire of different metals are seen a study of their relative sepsis rates would be of interest. It seems likely, however, that ancillary factors such as roughness of finish or extent of bacterial contamination might well be more important than the nature of the metal itself.

Turkey-meat and Tryptophan

Q.—May white chicken-meat be used as an alternative to white turkey-meat in a low tryptophan diet?

A.—Though the beneficial action against psoriasis of a diet containing turkey-meat has been attributed¹ to its low tryptophan content, the validity of this explanation is still doubtful. There is no satisfactory evidence that turkey-meat, either white or brown, is low in tryptophan. The absence of this essential amino-acid from any form of meat derived

from healthy musculature would seem surprising.

Without taking the question of colour into account, turkey and chicken meats have been found to contain about equal amounts of tryptophan. The good effects claimed for the turkey-meat diet can best be regarded as an empirical observation and not as a basis for theory. The substitution of chicken for turkey would not be expected to diminish the efficacy of the diet, but this point apparently has still to be investigated.

Psoriasis has long been believed to be aggravated by a diet rich in meat. Possibly some forms of meat are more harmful than others, with meats from birds less harmful than meats from mammals.

Alternating Hyperglycaemia and Hypoglycaemia

Q.—Is there a disorder of the carbohydrate-regulating mechanism in which bouts of hyperglycaemia are followed by bouts of hypoglycaemia sufficient to cause symptoms?

A.—The typical example of this is the lag type of glucose tolerance which occurs after operations on the gastrointestinal tract, such as partial gastrectomy. A similar response is sometimes found in apparently normal individuals, some of whom may eventually develop diabetes.

Alternating hyperglycaemia and hypoglycaemia occur in poorly controlled diabetics and in those with accompanying adrenal or pituitary insufficiency—for example, after hypophysectomy. Presumably, however, diabetes is not present in this patient, and there is no question of the surreptitious administration of insulin. Even though hyperglycaemia is said to be followed by hypoglycaemia, it would be wise to investigate the patient for other causes of hypoglycaemia.

Malar Flush

Q.—What is the explanation of the "malar flush" in patients with lobar pneumonia, and why do patients with apical pneumonia sometimes present with cerebral symptoms?

A.—The malar flush is due to cyanosis, and this is attributable to unoxygenated blood passing through areas of unaerated lung so that there is poor respiratory exchange. Pain may play a part in diminishing respiratory excursion, and of course in the worst cases cyanosis may accompany peripheral circulatory failure.

I have not heard of any satisfactory explanation for the confusion and delirium that commonly accompany apical pneumonia. Any patient with pneumonia may develop cerebral symptoms, presumably from factors such as toxæmia, anoxia, and retention of carbon dioxide. It is important to bear in mind in this context the occurrence of meningitis and cerebral abscess and the susceptibility of the alcoholic to pneumonia.

Book Reviews

Young Criminals

The Young Offender. By Dr. D. J. West. (Pp. 333, 35s.) London: Gerald Duckworth, 1967.

A review of the state of knowledge of the incidence of crime in young people is well-timed. The book includes a scholarly presentation of the literature of its aetiology and treatment. Dr. West casts doubt upon the reality of the recent increase of juvenile delinquency and calls attention to the trivial nature of much of it, comprising largely cases of larceny and breaking and entering (79% of all indictable offences in young people). There seems no increase of recidivism beyond that allowed for by the increase of population. Convictions for drunken behaviour, the use of prohibited drugs, vandalism, and assault have increased. The majority of young offenders seem not very different from groups of non-convicted, self-admitted delinquents.

Dishonest behaviour often seems more closely linked to the situation in which the juvenile finds himself than to any personality characteristic. The black-out in the north-east of the United States in 1965 led to a spate of looting. Experiments are referred to when the release of aggressive behaviour in normal subjects has been provoked by mild authoritative persuasion. Social pressures alone are not the determinant; multifactorial explanations seem more convincing. Poor education and health, broken homes and lack of adequate parental control, low salaries, and poor housing seem elements of a complex social handicap in

association with other personality and situational factors. The increased pressure towards conformity leads to greater strain upon the socially handicapped, and aspects of the English educational system are criticized for contributing to this.

The changing views on the influence of constitutional factors in juvenile delinquents are recounted. A strong case appears to have been made out for the existence of inherited factors in some serious and persistent criminals, but generally the influence of heredity seems small. A lack of verbal skills rather than poor intelligence is more characteristic of delinquents in general. The influence of minor physical handicaps, minor degrees of brain damage—sustained perhaps at childbirth—abnormal E.E.G., and the association of certain body types are comprehensively documented. Behaviourist theories are lucidly presented and related to psychoanalytic and sociological viewpoints. Adequate reference is made to the work of Piaget on moral development and maternal deprivation, the surveys of Douglas and Blomfield, the Cambridge-Somerville youth study, the important prediction tables of the Gluecks, and different attempts to classify delinquency.

Drug-taking and addiction and possible methods of their control are critically discussed. The incidence and types of sexual offence are competently dealt with. Such

offenders seem usually to have convictions for property offences also, but include many inhibited neurotic types quite different from the ordinary young delinquent. Reasons for the relative infrequency of female delinquency and an assessment of why wayward girls tend to be worse than delinquent boys are analysed. The expression of female maladjustment by promiscuous behaviour and the predominance of care and protection cases are adequately noted. The literature concerning pregnancy in the unmarried was presumably not thought appropriate to the author's task. A historical account of sentencing of young offenders includes nineteenth-century reforms, the development of approved schools and borstals. The innovations made in juvenile courts and the setting up of family councils is fully covered. In dealing with prevention the author argues for a failure of normal social control and efforts to strengthen these as having priority over measures for dealing with individual law-breakers. The treatment of delinquency in terms of reality and group therapy is discussed and an account of such methods as that of Aichhorn and other projects including behaviour therapy is given.

Throughout the book Dr. West uses the language of science in a field when speculative interpretation has often outweighed the facts of research. The book is carefully and logically arranged, is well written, excellently indexed, and is the most comprehensive account of its subject known to its reviewer.

JOHN S. BEARCROFT.

Obstetric Analgesia

Principles and Practice of Obstetric Analgesia and Anaesthesia. Vol. 1. *Fundamental Considerations.* By John J. Bonica, M.D. (Pp. 837+xvi; illustrated. £9 15s.) Oxford: Blackwell, 1967.

This is not armchair reading but a massive reference book to almost everything which can be conceivably connected with obstetric analgesia and anaesthesia. The present volume, which is the first of two, deals with the physiology of pregnancy and parturition and with the pharmacology and clinical effects of the various substances and methods used both for analgesia and for general and regional anaesthesia. The second volume, which is yet to come, will deal with the clinical side of analgesia and anaesthesia. The two volumes together look like containing something over 1,500 pages. By any standard this is a tome, but from the quality of the first volume an immensely important one.

It is essentially a comprehensive review of this field of medicine, and the documentation is therefore a particularly attractive feature. There is hardly a paragraph that does not

include a list of references; in some places every line has three or four. Bonica has already shown in his textbook on pain that he is capable of handling vast fields in a very detailed manner, and this book is further evidence of his capability.

However, even the best and biggest of books—and this surely falls into both these categories—tend to have a national or regional character, and this one is no exception. British readers must not be surprised, therefore, to find that in spite of the thoroughness of the rest of the book the common methods of analgesia used in Britain do not appear to be very important to the author. The self-administration of nitrous oxide is dealt with only in terms of mixtures with oxygen individually made up for each patient, and 75% nitrous oxide is advocated as a satisfactory concentration. Few anaesthetists in this country would be happy to leave a woman with this mixture. Nitrous oxide and air is dismissed in seven lines without any reference to the considerable experience which has accumulated here in 40 years of use, while premixed nitrous oxide and oxygen is not mentioned at all. Heroin is said to be still used in the British Isles, but the supporting

reference given is to a questionnaire sent out by the Association of Anaesthetists some 10 years ago to determine the use of heroin in general by anaesthetists. To this, only four out of 639 anaesthetists said they had ever used this drug in obstetrics.

Another curious feature, for a book which handles in such splendid fashion such a myriad of minutiae, is the juxtaposition of the abstruse and the obvious, the advanced and the elementary. Thus elaborate diagrams illustrate open drop ether, intubation of the larynx, and respiratory obstruction by the tongue. A massive reference book like this is hardly to be expected to offer somewhat elementary teaching material to junior residents and midwifery nurses.

These somewhat minor points caught the eye for obvious reasons. My overwhelming reaction to this volume is one of unstinted praise and recommendation for what must be the finest and most comprehensive book on obstetric anaesthesia and analgesia yet compiled. Everyone interested in the subject from houseman to advanced research worker or clinical teacher is bound to use this fine book sooner or later.

W. W. MUSHIN.

Microbial Disease

Recent Advances in Medical Microbiology. Edited by A. P. Waterson, M.D., M.R.C.P. (Pp. 355 + viii; illustrated. 65s.) London: J. & A. Churchill, 1967.

The forerunner of this new edition in the *Recent Advances* series, *Recent Advances in Bacteriology*, was published 12 years ago. Since then great progress has been made in the study of microbial disease, with major advances being made not so much in bacteriology but in the wider field of microbiology. The publication of this new edition under the title of *Recent Advances in Medical Microbiology* is to be welcomed for a number of reasons, not least because it may reflect a change in attitude towards the teaching of microbiology in medical schools.

It is natural that the number of subjects in a book such as this is limited, but they have been chosen with care to include those in which there have been major advances or in which a comprehensive review was needed. There are altogether nine chapters, five being devoted to various aspects of microbiology, one to the mycoplasmas, two to bacteriological subjects, and a final chapter on a protozoal infection, toxoplasmosis. All are complete in themselves and contain a useful set of references.

E. Norrby's chapter is straightforward and comprehensive, dealing in the main with the biological and antigenic properties of the virus and methods for measuring antibodies to measles, a subject to which the author has made important contributions. He discusses ways of achieving resistance against measles from which it is clear that he favours the use of killed measles vaccines. Whether he is justified in concluding that present evidence indicates that long-lasting immunity can be obtained with a killed vaccine is open to question, and for that matter there is as yet no evidence that a live vaccine will do so either. The next two chapters by D. M. McLean on aseptic meningitis and J. E. Banatvala on respiratory viruses bring the reader up to date with progress in these spheres which are of so much importance to the clinician. The chapter on diagnostic procedures by C. E. D. Taylor contains much information which will be useful to the clinician both on requesting tests for virological diagnosis and in interpretation of the results. The fourth chapter on a virological subject is by the late Alan P. Goffe on immunization against poliomyelitis. In it he gives an admirable account of the processes of immunity to poliomyelitis, and the story of the development of inactivated vaccines and later of attenuated vaccines is well told. This is an extremely well-balanced account of a complicated subject. It will be interesting to see whether Dr. Goffe's forecast that in the future vaccines will be prepared in human diploid cells will come to pass.

The discovery a few years ago that the Eaton agent, the causative agent of atypical pneumonia, was a mycoplasma has stimulated much interest in these organisms. As B. P. Marmion (his name is surprisingly misspelled in the first page of the chapter) records, much of the earlier work on these organisms in relation to veterinary bacteriology and studies on puerperal sepsis has been to some extent overshadowed by the discovery of the identity of the Eaton agent. This chapter describes in detail the general properties of these

organisms and methods for laboratory study. Their role as pathogens in man and animals is discussed in detail as well as the question of the possible association of these organisms with human leukaemia, certain solid tumours, and rheumatoid arthritis. The flag of bacteriology is kept flying in an article by R. Hare on the anaerobic cocci, and one on protein binding by G. N. Rolinson makes useful reading. The last chapter on toxoplasmosis by C. B. Beattie presents a fascinating account of the natural history and diagnosis of the disease caused by this parasite. It is an admirable choice of subject because in the past it has been largely ignored in textbooks, with too little detail on the clinical aspects in some and too much detail of the parasite in others. This lucid account will be of particular interest to pathologists and paediatricians.

This book is strongly recommended for pathologists, clinicians, and many others. At the present rate of progress a further edition will be required before another 12 years has elapsed.

J. A. DUDGEON.

Successful Surgery for Vesico-vaginal Fistula

The Vesico-Vaginal Fistula. 2nd edition. By J. Chassar Moir, C.B.E., M.D.(Edin.), M.A.(Oxon.), D.M.(Oxon.), F.R.C.S.(Edin.), F.R.C.O.G., Hon.L.L.D. Queen's University, Ontario, Hon.M.M.S.A. (Pp. 196 + ix; illustrated. 60s.) London: Baillière, Tindall & Cassell, 1967.

When this monograph first appeared in 1961 it was widely accepted as a gem among medical literature, and quite rightly. The second edition, in which the author's delightful personal style is preserved, is even better. It is a little larger because it contains new illustrations and additional sections which deal with the "circumferential" vesico-vaginal fistula, the construction of ileal and rectal bladders, and the treatment of ureteric injuries. The inclusion of the last (as well as of urethro-vaginal fistulas) is not inappropriate despite the title of the book, and serves to give the gynaecologist and urologist a complete picture of urinary fistulas in women.

The emphasis throughout this book is on the presentation of the technical details of operations (including instruments, suture material, and postoperative care) for the cure or circumvention of fistulas. Its object is to guide the surgeon who only occasionally deals with such problems and who is therefore likely to encounter difficulties and disappointments. In short, Professor Chassar Moir reveals the secrets which determine surgical success rather than failure. And no one is better qualified to do so since he has a unique clinical experience in this field, acquired in this country, in Africa, and in India. His record of achievement is remarkable. Of 350 patients suffering from fistulas of varied types and aetiology, two-thirds of whom had had 1 to 19 unsuccessful operations previously, only three were not treated surgically. And 255 vesico-vaginal and urethro-vaginal fistulas of traumatic origin were tackled with 100% anatomical success. No surgeon can afford to neglect the advice and tips given by one who can obtain results such as these.

Spalteholz in English

Atlas of Human Anatomy. Originally devised by Werner Spalteholz. 16th edition. Revised and re-edited by Rudolf Spanner. (Pp. 904 + xii; illustrated. £13.) London: Butterworth, 1967.

An English version of this atlas, well known to all anatomists since its first edition in 1895-1900, has been prepared in order to reach a wider public. This involved certain technical difficulties in that the plates, with their incorporated Latin terms, had already been printed. It was not possible to print both a running English text and lists of translated terms. The reader is therefore left with only a translation of Latin terms as far as possible picture by picture, although in some figures there are a few lines of useful commentary in English.

There is a wealth of anatomical information for the studious in these "pellucid images," even though the method of reproduction employed does not always succeed in giving the crispest of outlines. Colour is freely used, often to advantage and with clarification, but again in several figures achieves a certain haziness. Some of the neat diagrams in fact carry more conceptual information than the more spectacular contributions such as Fig. 754. This is labelled as a "composite diagram of the circulation," and is a masterpiece in its own right. Truly did Ruysch, the greatest of "injectionists," maintain that anatomy was blood vessels "variously arranged"; he would, even so, have hesitated before this phantasmagoria. Many of the radiographs, on the other hand, are quite excellent reproductions. The price of the atlas will, however, preclude any undergraduate buying it for himself. In this country it can only find a place in a dissecting room.

R. J. HARRISON.

Bile Pigments

Bilirubin Metabolism. Edited by Ian A. D. Bouchier, M.D., M.R.C.P., and Barbara H. Billing, Ph.D. (Pp. 294 + xii; illustrated. 63s.) Oxford: Blackwell, 1967.

This book gives a verbatim account of a conference held in the medical unit of the Royal Free Hospital in 1966. These international symposia have been held annually under Professor Sheila Sherlock's chairmanship for some years and now form an important contribution to medical literature. The present volume is edited by Drs. I. A. D. Bouchier and Barbara H. Billing, who are to be congratulated on the accuracy and completeness of the text.

The proceedings were divided into five main sections. The first on the origin of bile pigments was concerned with "early bilirubin" and includes important new information on this subject. The second section on the structure of bile pigments is mainly chemical. The hepatic transport of bile pigments was dealt with in the third section, and the last two were concerned with bilirubin metabolism in obstructive jaundice and with renal excretion of bile pigments.

With 50 contributors from 12 countries it is natural that many new experimental data were presented, and it is particularly valuable to have a complete record of the discussion

at the end of each section. It would be invidious to select any special article for comment, since the general standard is so high. The book seems to have appeared reasonably quickly after the conference, although the actual date is not mentioned. It can be strongly recommended both to clinicians and to laboratory workers interested in bilirubin metabolism.

N. F. MACLAGAN.

Cerebral and Spinal Disorders in the Young

Pädiatrische Neurochirurgie. Edited by Professor Joachim Gerlach *et al.* (Pp. 875 + xix; illustrated. DM. 287.) Stuttgart: Georg Thieme, 1967.

Paediatric neurosurgery is rapidly assuming an important position as a specialty in its own right, and a few surgeons in many countries are devoting their attention almost exclusively to the study and care of cerebral and spinal disorders in the young. There are numerous important differences in pathology, presentation, and prognosis between the surgical disorders of the nervous system in adults and in those in children and infants which demand special study and special modifications of treatment and management.

As a source of reference and information for the neurosurgeon and neurologist whose practice includes all age groups this new book, *Pädiatrische Neurochirurgie*, will prove invaluable. It will also, no doubt, be gratefully welcomed by paediatric neurosurgeons and their assistants as a detailed, comprehensive, and informed account of their specialty. The editors and most of the contributors are from the university clinics and hospitals of Würzburg and Vienna, but there are two contributors from Paris and one from the university of Groningen in Holland.

The work is in two parts. The first is a general section containing chapters on the anatomy, physiology, and embryology of the nervous system. Chapters follow on the examination of the central nervous system in infants and children, upon general clinical methods of examination, and special diagnostic procedures, referring separately, where appropriate, to the newborn, young children, and children of school age. Brief reviews of the bases of echoencephalography and

isotope scintillation scanning of the brain are included. There is also a useful section on anaesthesia and pre- and postoperative care.

In the second and larger part of the book the special pathology, diagnosis, and treatment of the various surgical disorders of the central nervous system in infancy and childhood are considered in methodical detail. Particularly valuable to the surgeon are chapters on some of the "medical" problems such as virus and parasitic infections and the demyelinating disorders of uncertain aetiology. This book is too detailed to be read from cover to cover by even the most assiduous student of neurosurgery, but it is a sound and orthodox work of reference. I am convinced that works of this calibre and scholarship dealing with a fairly small field should receive a wider readership by translation into other tongues.

There is an excellent general index, and a useful bibliography follows most of the chapters. The illustrations, x-rays, and diagrams are beautifully reproduced.

B. J. HARRIES.

Medical Society of New Jersey

The Healing Art. A History of the Medical Society of New Jersey. By Fred B. Rogers, M.D., and A. Reasoner Sayre. (Pp. 346 + ix; illustrated. \$10.) New Jersey: The Medical Society of New Jersey, 1966.

The Healing Art is an interesting account of the New Jersey Medical Society, which dates back farther than any other American or British medical society with the exception of the Royal Medical Society of Edinburgh. In the first chapter the authors give a brief account of early colonial medicine, which was very crude, as may be judged by the fact that John Wesley's *Primitive Physic* was much used. Throughout the whole book the stages of medical progress are described, and with just pride the authors point out how quickly the New Jersey Medical Society either took advantage of new discoveries or initiated reforms in the public health of the State.

The Society began on 27 June 1766, when fourteen physicians met together and signed the attendance book (still preserved) of this inaugural meeting. The first regular meeting of the Society took place a month later, but

for some years the Society met only twice a year, for difficulties of travel were great. The newly formed State Society recommended the physicians of each county to form a local medical society, and to elect delegates to the State Society. (By 1885 all 21 counties possessed a local medical society.)

During the War of Independence much fighting took place in New Jersey, and some members of the Society acted as medical officers in one or other army. Meetings of the Society were necessarily irregular during this period and for some time afterwards, for we learn that no meeting took place between 1795 and 1807. After that date the Society was re-established and has flourished ever since.

The Medical Society of New Jersey always had considerable political influence. As early as 1772 two members of the Society advised the two judges who granted licences to practise medicine in New Jersey, and for many years the Society possessed the right to grant an M.D. to suitable candidates. The Society often discussed the question of fees, and rightly so, because in 1849 it was stated that one-fourth of the members of the Society left their families destitute.

During the last hundred years many thousands of immigrants from Europe entered the State, so that in 1912, when the New Jersey Midwife Association was formed, it was necessary to provide lecturers in English, German, Italian, and Polish. The number of doctors increased along with the population, and in 1965 its membership reached 7,316 out of a total number of 8,734 doctors in the State. The Society always strongly opposed any undue encroachment of the State or Federal Government on the legitimate province of the general practitioner, and supported measures (such as the Blue Shield) that encouraged insurance for health by the individual.

Throughout the book there are numerous short biographies of physicians who have played an important part in the Society, and a timely tribute is paid to the many famous pharmaceutical firms whose centres of research are situated in the State of New Jersey. In 1928 a Women's Auxiliary to the New Jersey Medical Society was founded and since then has published a short history of its foundation, including an illustrated map of New Jersey. We commend its foresight, for this reviewer of *The Healing Art* had frequently to refer to an atlas.

GENERAL PRACTICE OBSERVED

Use of General Practitioners in the School Health Service

ALAN R. BUCHAN,* M.D., D.P.H.; A. PARRY JONES,† M.B., B.CH., D.P.H.

Brit. med. J., 1967, 4, 797-799

In recent years there has been increasing discussion on the use of general practitioners in the school health service. This has been motivated undoubtedly by the desire to secure better integration of the curative and preventive services, and to provide a more effective service for the schoolchild. Attempts to bring general practitioners into the school health service, however, raise administrative and organizational problems which are almost insurmountable, and so local education authorities have tended to employ selected general practitioners on a sessional basis in the neighbourhood of their practices but not solely on their practice patients (Chief Medical Officer, 1966a).

For some this is not acceptable, and a recent editorial in the *Practitioner* (1967) asks: "Has not the time come—indeed, been long overdue—when the care of our children be placed fairly and squarely upon the shoulders of family doctors. This would involve, among other things, routine medical examination of every child on first going to school. If any condition be found that should require special consideration, then the school authorities should be informed. The function of what would then be a much depleted school medical service would be the supervision of handicapped children—for example, the hard of hearing, the partially blind, the epileptic, the crippled. In this capacity they would act as paediatricians in conjunction with the local children's hospital."

In Somerset an attempt has been made to employ general practitioners in this more radical manner, and it is hoped that our experiences with a pilot scheme may be of interest.

Early in 1966 a full-time school medical officer retired unexpectedly. He had been solely responsible for the schools in a thinly populated and rural part of the county. The only towns in his area had populations of 3,000 to 4,000, and all of these were some miles apart. In the main, the general practitioners practised in groups from these towns, and each practice tended to have a distinct and local sphere of influence. Thus the majority of schoolchildren in each primary school in the area were patients of the local practice. Even in the secondary schools, which had wider catchment areas, circumstances were such that general practitioners could be employed to carry out school medical work on their own practice patients without causing chaos in the schools.

The Scheme

The scheme was confined to the Wincanton Rural District and covered 1,253 children at 15 primary schools and 821 children at three secondary schools, one of which had boarding facilities.

* Deputy Principal School Medical Officer, Somerset. Now Principal School Medical Officer, Leicestershire.

† Principal School Medical Officer, Somerset.

Eleven general practitioners in the selected area were approached and all agreed to participate. They were asked to undertake all the duties (as under) carried out by full-time school medical officers, with the following exceptions: examinations under S.34 of the Education Act, 1944 (to "ascertain" which children require special educational treatment); examinations under S.57 of the Mental Health Act, 1959 (to find those children thought to be unsuitable for education at school); and Heaf testing and B.C.G. vaccination for schoolchildren registered on their National Health Service list or that of the practice. For children from other practices different arrangements were made (see Results, below).

Duties Required of Practitioners.—(1) Basic routine medical inspections at school entry. (2) Selective examinations at school-leaving age and at an intermediate stage. (3) Special examinations as necessary after referral by heads of schools, educational psychologists, parents, etc. (4) Re-examination of children previously found to have defects. (5) Accident cover. (6) Completion of immunization and vaccination programmes (Modified Schedule P). (7) Annual hygiene inspection of school and report.

Routine screening tests were continued as for other parts of the county, as were the services of the school nurses, educational psychologists, peripatetic teachers of the partially hearing, and speech therapists.

Full-time county school medical officers were expected to deal with the ascertainment of physically and mentally handicapped children, problems associated with special educational treatment, B.C.G. vaccination, and with the children of those general practitioners outside the area who were not in the scheme.

Initially both parties had misgivings. The schools and our committee appreciated the value of having the services of family doctors who were on the spot, but had doubts about whether they would have sufficient time to devote to their new duties. Some felt that a full-time school medical officer wholly in county employ offered a second line of defence in the detection of defects in schoolchildren, and that a new pair of eyes could discover defects that previously had been missed.

In preliminary discussions all the general practitioners stated their preference for payment on a sessional basis, but were persuaded to accept an annual capitation fee despite long-standing antipathy towards this form of payment. However, it was thought likely that the general practitioners would not wish to devote a full two and a half hours one or more times a week to school work, but would develop a pattern of short though frequent visits to schools, thus providing closer linkage than could be given in this rural area by the existing full-time school health service. Remuneration by capitation fee obviated

the need for the general practitioners to keep records of the time that they worked, and it did away with the need to impose definitions of sessions and norms of work—for example, 15, 18, or 20 children per session. Though the doctors had reservations about "open-ended contracts" they agreed to accept them and to keep careful records of the time and effort involved for the duration of the trial.

Finally, it was agreed that fees from the local authority for vaccination and immunization record cards would continue until April 1967, and thereafter the practitioners would claim the revised fees for each procedure from the Somerset Executive Council.

Results

The scheme started in January 1967, and Table I gives the number of pupils on the register of each school and the number inspected during the spring and summer terms. Some 572 children were found to be on the lists of practitioners outside the prescribed area and for whom separate arrangements were made.

TABLE I.—*Number of Pupils on the Registers of the Maintained Primary and Secondary Schools in the Selected Area and the Number of Pupils Inspected by Practitioners*

School	No. of Pupils on Register	No. of Pupils Covered by G.P.s in Scheme	No. of Pupils Inspected by G.P.s		
			Arrears of Inspections	Current Inspections	Total
15 Primary schools ..	1,495	1,253	219	422	641
3 Secondary schools	1,151	821	231	44	275
Total	2,646	2,074	450	466	916

The spring term was devoted mainly to the examination of those children who had missed routine school inspections and re-examinations at the appropriate age owing to the illness of the now retired medical officer. In all, some 916 children were examined during the two terms, 608 of whom were seen for periodic inspections.

The number of pupils inspected at periodic inspections, together with the numbers found to require treatment (excluding dental disease and infestation with vermin), are given in Table II. Of the 159 pupils found to require treatment 50 were recorded as having visual defects.

TABLE II.—*Number of Pupils Medically Inspected at Periodic Medical Inspections, Together with the Number Found to Require Treatment (Excluding Dental Disease and Infestation with Vermin), During the Spring and Summer Terms 1967*

Age Group	No. of Pupils Inspected	Individual Pupils Found to Require Treatment	
		No.	%
5	53	16	30.2
6	162	35	21.6
7	91	39	42.9
8	39	7	18.0
9	25	7	28.0
10	23	9	39.1
11	85	14	16.5
12	34	7	20.6
13	20	3	15.0
14	12	5	41.7
15 and over	64	17	26.6
Total	608	159	26.2

The rate of defect finding (26.2% of children examined) compared favourably with that for the whole county, which averaged 18.3% over the previous five years, and the 15.8% for England and Wales (Chief Medical Officer, 1964, 1966b) over the four years 1962–5.

Seventy-one per cent. of the examinations carried out by general practitioners were attended by parents, compared with 64% for the remainder of the county area. The increase was

noticeable in the secondary school age group, where over a third of the children were accompanied by a parent.

Some 42 children were referred to appropriate specialists for further advice or treatment as follows:

Referred to orthopaedic clinic	20
Referred for ascertainment under S.34 of Education Act 1944	9
Referred to audiology clinic	6
Referred to child guidance clinic	4
Referred for speech therapy	3

The remaining 67 pupils were treated by the general practitioners. These defects fell broadly into three groups—namely, respiratory tract infections, skin disease, and minor emotional and behavioural disorders. By dealing satisfactorily with the behavioural disturbances, our impression is that the practitioners substantially reduced the number of referrals to the child guidance clinic.

These preliminary statistics appear to offer no support to the contention that general practitioners would find fewer defects than full-time school medical officers, and the system had the undoubted advantage that the doctor who found the defect was also responsible for its continuing treatment.

At the end of the summer term all the doctors and the schools were visited by one of us (A.R.B.) in order to assess the reactions of the participants. In general, the schools thought that the scheme offered considerable advantages to the children (and to the schools) over the traditional school health service, mainly because of closer contact with the doctor and ease of reference of problems at local level. The schools were also impressed that the new system had been well received by the parents concerned.

From the point of view of the school the scheme involved co-operation with more than one doctor, and necessitated coping with different techniques, and, more important, an increase in the frequency of visits. Most schools found that there was an additional work load placed in the school secretary, but part of this burden was occasioned by the backlog of children not examined, and by the newness of the system. One or two of the larger secondary schools were served by two and occasionally three practices. As might be expected, clerical difficulties increased when more doctors were involved with the school. In our view, and in that of the head teachers, these disruptions in the life of the school were more than outweighed by the advantages in having general practitioners doing the work. All are agreed, however, that a further increase in the number of doctors visiting a school would be undesirable. In urban areas the children at each school may have up to 20 different general practitioners. If the school health service is to be carried out in a school setting the number of general practitioners serving each urban school would make the administrative burden intolerable. In towns general practitioners could undertake school health work either on a sessional basis with one practitioner to each school or by conducting the examinations in their own surgeries. The latter solution would break the ties with the schools and in our opinion would be unacceptable to most teachers.

The general practitioners were, on the whole, well satisfied, and all agreed to continue the scheme. Several general practitioners appreciated the opportunity of acting as school doctor, and mentioned that there was no longer any likelihood of anxious parents presenting problems, previously discussed with their family doctor, to an unsuspecting school medical officer. We were impressed by the enthusiasm with which they carried out the work, and felt, like Didsbury (1964), that selective medical examinations were better carried out by doctors who already had a detailed knowledge of the child and its background and family. Referral for specialist advice and treatment had been simplified, and subsequent follow-up with the school had been improved.

Summary and Conclusion

An account is given of a trial project in Somerset employing general practitioners to undertake school health service duties for schoolchildren registered on their National Health Service list or that of the practice.

After the trial had lasted two terms everyone concerned wished to continue the scheme. Undoubtedly both parents and teachers appreciated having their own family doctors acting as school medical officers, and this advantage clearly outweighed the increased clerical work for the school. From the outset we

thought that these arrangements could only have a chance of working in a rural area. This view has been confirmed.

MEDICAL HISTORY

A Letter from Sir Morell Mackenzie

MAXWELL ELLIS,* M.D., M.S., F.R.C.S.

Brit. med. J., 1967, 4, 799-800

A few months ago Sir Terence Cawthorne was moving house and was in the usual dilemma of what to take with him and what to leave behind or give away. Among the gifts was a fine mounted, framed, and signed Spy cartoon of Sir Morell Mackenzie, of which I was the fortunate recipient. I wanted

to hang it in my room at the Institute of Laryngology and Otology and decided that it should be reframed to match the other pictures. When the frame was removed the apparent signature "Yours truly, Morell Mackenzie" was found to be the ending of a letter which had been folded behind the picture,

exposing the signature to give the impression of an autographed portrait. The letter must have been in this position for a good many years, forgotten or unknown. The ink of the signature is greatly faded compared with the rest of the letter. The paper was dry and split at the folded edges, but the script is easily legible. Through the kindness of Dr. Noel Poynter at the Wellcome Institute the letter was carefully restored and mounted and is now in our historical museum at the Institute (see Figure).

Mackenzie was writing from Potsdam, the palace of Emperor Frederick III at Charlottenburg, and had been in almost constant attendance on the Emperor for four months, enduring the emotional professional complications which have been so exhaustively described by Mackenzie himself and many others. In Mackenzie's book *Frederick the Noble* he has a note on 10 April 1888 of the Emperor's remark about the patients in England almost identical with that in this letter of six weeks later, but the letter is unrecorded. It is of some additional historical interest as it is an uninhibited *cri de cœur* from the writer in a private communication to a friend. Mackenzie reveals how keenly he felt the anomalous position he was in and how he found it impossible to extricate himself. However, the Emperor's condition rapidly worsened and he died just over two weeks later, on 15 June.

By all standards this was a difficult case, the management of which was made more difficult by the blaze of publicity in which it was conducted and the personalities and jealousies of the numerous doctors concerned. Lionel Colledge held strongly

* Dean, Institute of Laryngology and Otology, London W.C.1.

Königsches Schloss
Charlottenburg
May 27 1888

My dear Cork

Thank much
for a small contribution
to the *Forbes*. A letter
from Lodge Place Harley
makes me feel very
much inclined to leave
this hole and retire to my
native river. I fancy
from the photographs I have
received that "The Little
House" has been
greatly improved since
I was at Wargrave.

My own idea is to when I have
be back in England
again. When I see a
time the Emperor seems
anxious for me to go, but
when the time comes for
my leaving he moves
suggests my departing
my departure for a little
time he does in the most
delightful way, saying
"I know your journey must
want for very much"
and "What can your
patients in England do
without you etc. But
all the same he seems
to think it quite
natural that I should
stay on! I don't like
to tell you I cannot
get away. This is most
disagreeable position but
I must in. I hope
Cork is well and
that the air there
is flourishing. It seems
as if you would send
him a letter before
I come back.

Yours truly
Morell Mackenzie

that the tumour from which the Emperor suffered probably arose below the vocal cords (subglottic), a condition which often presents diagnostic difficulties even nowadays. In 1887 the early diagnosis of such a lesion was virtually impos-

sible, and with the treatment available the outlook almost hopeless even if a diagnosis had been made. This illness must have been among the most fully recorded in medical history and one of the saddest from so many points of view.

CONFERENCES AND MEETINGS

Family Doctors Practising from Health Centres

[FROM A SPECIAL CORRESPONDENT]

A conference of family doctors practising from health centres was held at the Ministry of Health in London on 21 December. Opening the conference, the chairman, Sir GEORGE GODBER (Chief Medical Officer, Ministry of Health) said that it had been directly inspired by a letter to the *B.M.J.* by Dr. E. J. Lace and Dr. H. I. Howard, of Bristol (7 October, p. 49), which had suggested that the time had now come for a conference of general practitioners who actually worked in health centres to pool their views and iron out problems. It was not generally appreciated, Sir George said, how rapidly progress was occurring in developing health centres. Whereas only a few had been built from the beginning of the N.H.S. to 1965, since the latter year 23 had been built, 38 centres were under construction, and plans for a further 50 had been approved. For the 10 years before 1965 only £70,000 had been spent on health centres in every financial year; since then figures for the succeeding financial years were £340,000, £1 million, and £2 million, respectively—and in future he hoped that three times this last sum would be spent.

Why the Conference was Suggested

Giving his reasons for suggesting the conference, Dr. HOWARD said that several previous conferences had been held on the subject of health centres. Almost all of these had been devoted to contributions by well-intentioned theorists and paramedical workers. A number of articles had also been published on the subject by interested academics. Nevertheless, the views of the general practitioners working in the centres remained unknown, and what was wanted was an exchange of ideas. In his opinion the present-day family doctor working from a health centre had the opportunity of being a complete doctor, with co-operation from academic staffs and hospital consultants. It was almost 50 years since the Dawson Report had first defined a centre—but the authors of the report could never have envisaged the effects of such things as the population explosion and the brain drain.

The discussion on "The Health Centre and Hospital Service" was opened by Dr. M. A. SLEE (Witney, Oxon.). His centre, which had started two years ago, was situated 13 miles (21 km.) from the nearest district hospital at Oxford. It offered general-practitioner, local authority, and virtually full consultant services in the same building. Of the last, 28 sessions were held every month, though there were no sessions on otorhinolaryngology and children's and skin diseases. There were advantages for both patients and

doctor—the absence of travelling, and the ease of consulting with the specialist and obtaining a direct opinion. Diagnostic facilities at the centre included an x-ray department and a pathological laboratory, both of which were manned by part-time technicians, and even their own thermography unit. Doctors working there had established informal links with the teaching hospital at Oxford, with students undertaking attachment and attending outpatient sessions with the consultants.

Casualty services were restricted to minor injuries, and often these patients were seen by the nurse in the first instance. Concluding, Dr. SLEE emphasized that this centre had been founded by private capital and not by the Ministry of Health.

Dr. G. W. PAGE (Coventry) stressed the importance of geographic factors. It was not an economic proposition to have a casualty department and diagnostic facilities in a health centre when the hospital was just round the corner. He himself had a clinical assistantship in the orthopaedic and accident department in his local hospital, and he wondered whether, in collaboration with industry, it was not possible to develop peripheral casualty centres. These would not treat major injuries but would do much to relieve the load on the central hospital.

Speaking as the representative of a university teaching health centre, Dr. H. W. ASHWORTH (Manchester) said that it had been shown that it was uneconomic to provide diagnostic facilities in a health centre if there was open access to these in a local hospital. What was needed was really quick service. Dr. J. A. M. VASEY (Risca, Monmouthshire) spoke of difficulties in transporting specimens to the pathology laboratory, which was 5 miles (8 km.) away. In his view there was sometimes a strong need for a general-practice diagnostic unit, particularly when there were excessive delays; in his area it might take six weeks for a plain x-ray film, nine months for a barium meal, and ten months for a barium enema to be done.

Value of Consultant Services

Dr. G. G. WARD (Ottery St. Mary, Devon), who practised with two other doctors in a rural area with 8,000 patients, emphasized the value of consultant sessions in a health centre, for both the patient and the general practitioner. There was an excellent service for pathology tests from the laboratory of their local hospital. The family doctors had their own haemoglobinometer and electrocardiograph, and, armed with the results of tests done beforehand, they could present a "worked-up" patient to a visiting consultant.

Dr. D. H. KAY said that at Hythe (Hants) they had been fortunate in having a health centre built on to a pre-existing cottage hospital. A casualty service was provided by a rota of general practitioners, and they had a minor operating-theatre and an x-ray unit. Part of the success of their centre was due to the contact with the postgraduate medical centre at Southampton, 11 miles (18 km.) away. He thought that one of the most important things to have come out of the health centres so far was the increased mutual respect between consultants and general practitioners.

Dr. W. A. BROWN (Peterlee, Co. Durham), who said that their requests for consultant sessions had been rejected, called for residential accommodation to be provided for two medical students in every health centre. He and his colleagues at the centre were co-operating with the local technical college in the training of medical secretaries.

Dr. R. H. GLENDINNING (Bristol) asked what was the best size—for the health centre building, its staff, and the population served. He thought that the optimum size lay somewhere between the single-doctor centre, of which there was one in Devon, and the vast polyclinics found in Eastern Europe. Could the essential doctor-patient relationship be preserved with a large team which included laboratory technicians and visiting consultants? He had found after working in a centre for four years that his referrals to hospital consultants were now more specific—for example, he now referred an individual patient to a genito-urinary specialist rather than to a general surgeon.

Sir GEORGE GODBER asked whether it was a waste of doctors' time to do too many laboratory investigations themselves. Where should the main diagnostic services be situated? What was needed was a specialist service based on the hospitals, and a generalist service based on the health centres.

Size of Health Centres

Discussing the size of health centres, Dr. VASEY emphasized the need to plan for increases in the population served. Since their centre at Risca had been planned the population had risen from 10,000 to 14,500. The centre was now too small to serve these people properly and he was worried lest the good work already done should be wasted because of lack of space. Dr. S. DILLON (Rugely, Staffs) said that they had the same problem, with a continual rise in the number of patients served by the practice. Should the health centre be enlarged, or should it stay at its present size and develop satellite centres? Dr. BROWN said that at Peterlee they had resisted the temptation to build

satellites and had built more consulting suites at the main centre.

Dr. L. ROODYN (London) pointed out that it had been shown that a population of at least 60,000 was needed for x-ray and consultant services to be provided on an economic basis; hence they probably could not be provided in health centres. He thought that a third of all patients coming to the surgery did not need to see a doctor, but could see a nurse. The patients themselves would accept this approach, and the nurse should work on an appointments system.

Speaking of ancillary workers Dr. A. DUNNILL (Oxford), said they already used the district nurse to do simple treatments on patients at home. In their practice the midwives helped the general practitioner at the antenatal sessions and in the maternity unit, which was linked to the specialist unit and the teaching hospital.

Dr. D. A. MOORE (Buckfastleigh, Devon), who practised with a partner in a health centre serving a scattered rural population of 4,500, also spoke of delegating work. It was no use having high-powered equipment in a centre if there was no time for the doctor to use it. Recently he had concluded that only one out of eight patients seen on a visit needed to be seen by a doctor. They had recently abandoned a branch surgery to get one extra visiting day a week.

Dr. ASHWORTH said that if the nurses were to do visits and treat patients a change in the attitudes of both doctors themselves and of the Royal College of Nursing would be needed. Dr. A. J. BRAY (Ilfracombe) urged doctors not to lose sight of the personal element of general practice. Consultations should still be run on traditional lines, with the patient seeing his own doctor, and sufficient time would be gained by centralization and the introduction of an appointments system.

Role of Practice Nurse

Dr. R. N. CARTER (Peterlee, Co. Durham) spoke of their two months' experience with a practice nurse, who divided her time between district visits and work in the surgery. Some of these sessions were by appointment, and her other duties included taking the blood pressure of patients with hypertension and weighing obese patients. Future duties planned included taking smears for cervical cytology, visits to the chronic elderly sick, and follow-up visits to patients with minor illnesses.

Dr. H. E. BACH (Harlow, Essex) thought that some first visits could be done by nurses. He called for interchangeability of nurses' superannuation rights between hospital and general practice. Dr. R. H. GLENDINNING (Bristol) said that they were trying to abolish the boundary between what the general practitioner and what the local authority was expected to provide. Though in their own practice all the clinical work was done by doctors, many duties were delegated to the nurse—thus she did 200 venesections a week, for which the doctors took full responsibility. At the child welfare clinics the family doctor was in one room, and the health visitor in another.

There was also a geriatric clinic, based on the age-sex register compiled at the centre. A carefully worded letter was sent to patients on the practice list who were about to retire

asking them to come to the centre for a check-up. The health visitor visited the patients and inquired into the patients' social circumstances; a very full medical examination was done by a local authority medical officer; and the patient was referred back to his own general practitioner if treatment was needed. The number of visits required to the chronic sick patient had gone down considerably.

Dr. Page emphasized that the health team must be a permanent one, with nurses of high quality who received additional training in medicine as seen in general practice. A seven-year experience of working with a psychiatric social worker had convinced him of their value, particularly in dealing with emotional and marital problems and with patients of inadequate personality.

Miss A. M. LAMB (Deputy Chief Nursing Officer, Ministry of Health) pointed out that because of the general shortage of nurses it was essential for them to be used for the tasks for which they had been trained. Nevertheless, there was a place for all types of nurse in the community services. Job-satisfaction was of paramount importance for the health centre nurse, and in this communications were all-important; doctors and nurses must meet at least once a week. She emphasized that State-registered nurses working in the community had already been trained to the standard of ward sister, and they had usually had additional training in community services. These workers must be kept up to date with developments, from the nurses' point of view. Finally, Miss Lamb referred to the conditions of service, saying that the provision of cars, housing, adequate off-duty periods and holidays, and refresher courses were essential.

Dr. G. H. LEWIS (Harlow, Essex) regretted that in some health centres the nurses' first loyalty was to the M.O.H. and not the family doctors. He called for more flexibility by local authorities. Miss Lamb pointed out that this situation described a liaison scheme and not a true nursing attachment. Full consultation between doctors, nurses, and the local authority chief nursing officer was essential in planning attachment schemes, and an agreed local scheme took a minimum of three months to draw up.

Taking Patients to Doctors

Dr. VASEY described an experimental scheme for transporting patients to the health centre, which was sponsored by the Ministry of Health and was due to start on 1 January 1968. If the scheme was successful it might reduce the work load tremendously, and possibly 30% of patients who requested visits might be taken to the centre. Two minibuses had been bought, and an extra secretary engaged to deal with the scheme. Though extra consulting time would have to be provided, he thought that this would be an economic proposition.

Continuing, Dr. Vasey spoke of two fears. Firstly, that the scheme might be abused and used merely as a transport service. Secondly, if the scheme failed, that the visiting rate might rise rapidly and the doctors would be unable to cope.

demanded from doctors for maintenance costs attached to large health centres for transporting patients and specimens to the pathological laboratory. Dr. D. FARQUAR (Romford, Essex), referring to the high sums being

demanded for doctors for maintenance costs and ancillary help at health centres, said that caution was necessary with these grandiose schemes. Eventually the general practitioner might find himself paying for the transport service out of his own pocket.

Dr. BACH called for the Ministry to encourage the Bristol family folder scheme [*B.M.J.*, 1965, 1, 662] and asked what was the value of an intercom system.

Dr. KAY said that their intercom was at once a great help, particularly for doctors, midwives, and the mental welfare officer travelling in their cars, and a distraction—for example, when it disturbed a consultation. Dr. W. L. SELKIRK (Liverpool) had found it of great value, and they had agreed if a doctor did not answer the first signal that it would not be repeated for five minutes. Discussing the management of health centres, he suggested that the ideal person for this was a retired general practitioner. Every future health centre should consider appointing a manager.

Design and Function

Dr. BRIAN DIDSBURY (Ministry of Health) discussed the design and function of health centres. The present-day ones, in his view, were good examples of how they should not be built. Far too many of them had neglected the key role of the family doctor, not only in relation to traditional medical practice but also to the remainder of the community services. Thus some health centres were basically branch surgeries; others had separate wings for general practitioners and local authority services. He called for enlightened participation by general practitioners at the design stage of health centres. The advantage of the English system was the flexibility of design to meet local conditions of practice.

Practical difficulties were encountered in health centres serving over 25,000 patients; above this figure many facilities had to be duplicated—otherwise an institutional atmosphere was created.

Sir GEORGE GODBER asked what was the optimum size of a health centre. Dr. WIGRAM said that it was not the size that was of critical importance but the number of groups of doctors working within it. Dr. CARTER said that at Peterlee there were 18 doctors, eight partnerships, and four consulting-rooms—and the system worked well. Dr. SLEE thought that six doctors was the right size for a group. They had made it a rule for the doctor always to speak to a patient if he telephoned, and with this number of doctors the telephonist could always contact them. Dr. LEWIS said that at Harlow in Essex they had found that one large partnership served the needs of the new town best. This was a special sort of community, with unsettled, newly moved people who often liked to change their doctor until they found what they thought was the right one.

Speaking of interesting young doctors in general practice, Dr. VASEY said he had recently shown a group of students from Cardiff round their health centre. They had made two main comments. Firstly, they were quite taken aback that the general practitioner was expected to see a patient every five minutes. Secondly, they thought that general practitioners ought to have some institutional responsibility, whether a few general-practitioner beds or in a general-practitioner maternity unit.

Correspondence

Letters to the Editor should not exceed 500 words.

Requests for Abortion

SIR,—The anticipated increase in requests for termination of pregnancy would appear to have materialized. At my gynaecological outpatient clinic in the Hospital for Women, Birmingham, on 12 December there were seven such referrals from local doctors. The majority of these patients had been given urgent bookings at the clinic at the special request of their general practitioners. The time required for proper assessment of these patients interfered materially with the proper treatment of the remaining patients, and incidentally with the lunch-time arrangements of my staff and myself. One termination was advised, one patient was referred to the cardiologist for his opinion, and one was referred to the medical social worker for her assessment. In no case was referral to a psychiatrist deemed necessary.

These patients included one whose referring practitioner advised specifically against ter-

mination, and another girl, aged 20 and unmarried, who had previously had a pregnancy terminated last July and was now pregnant by another man. My mail the same morning had contained a letter from a nurse, who was also a doctor's daughter, requesting an appointment to discuss termination, but who could not get a referring letter because her practitioner was her father's partner. My antenatal clinic the following day included one more patient requesting termination against the advice of her practitioner.

If every unexpected conception is to be referred to a gynaecologist for comprehensive consideration of indications for termination, it is difficult to see how this can be contained within the present gynaecological structure of the National Health Service.—I am, etc.,

Clomiphene for Ovulation

SIR,—I apologize for this rather long and detailed reply to Dr. Arnold Kloppe's letter (16 December, p. 680), but as I disagree with practically everything he says and as our disagreement is one of fundamental principle rather than technical detail I must answer his points *seriatim* and rather fully.

He takes me to task for saying that steroid chemists should "get on with their research work" rather than waste their time doing innumerable oestrogen (and pregnanediol) assays to select suitable patients for clomiphene therapy and to monitor the day-to-day response to the treatment. As a do-it-yourself gynaecologist who is familiar with the laboratory as he is with the clinic and operating theatre, I would have thought he would have agreed that steroid chemists still have an enormous amount of research to do, especially in methodology, and that few laboratories were so equipped as to afford the time, the pairs of hands, and the money to do so much routine work as your leading article (25 November, p. 434) suggested was essential when there are other adequate methods of assessment and monitoring.

He contends that the selection of suitable women for treatment, the identification of amenorrhoeic subjects with sufficient residual ovarian activity to respond to the treatment, and the detection of women with regular but persistently anovular cycles require "accurate hormone assays." Hasn't he got the picture somewhat out of focus? Suppose one just gave a course of clomiphene to such an amenorrhoeic woman and saw whether it produced a period or not. This would demonstrate whether she had sufficient residual ovarian activity to respond to the treatment.

Suppose one supplemented this with daily basal temperature records. This, in my experience of careful charting of many thousands of records over at least 20 years, would tell you in at least 80% of the cases whether the response, if there was one, was ovulatory. Incidentally, I have found that it is very rare to have regular anovular cycles. Furthermore, suppose one had a vaginal cytology unit at one's disposal, which should be much more likely than a steroid chemistry unit capable of performing "accurate hormone assays," one could certainly answer these questions.

He says that "few would deny" that vaginal cytology is inadequate for "categorizing" the women subjected to treatment or determining the nature and timing of their response. How many gynaecologists in this country have sufficient experience of endocrine vaginal cytology and its capabilities? The answer is "few" and it is these few who would deny Dr. Kloppe's contentions. Most certainly serial vaginal smears can "categorize" and determine the nature and timing of the response.

He says that by means of hormone assays (and I suppose he means urinary oestrogen estimations) "most advanced laboratory services" can predict the day of ovulation. Dr. Sommerville's Endocrine Laboratory Unit at Chelsea can't and I should have been very surprised if it could. Just because the urinary oestrogen level is so many $\mu\text{g.}$ on day x of the cycle it certainly doesn't mean it will reach an ovulatory peak on day y . Nor is it our experience that the hormone assay pattern of one cycle is necessarily likely to repeat itself in subsequent cycles.

He implies that one can only determine that there is any ovarian response, that the oestrogen response is equal to or much above that of the normal cycle, whether ovulation occurred, or how adequate the luteal phase was by the urinary hormone assay. We contend at Chelsea that we can answer these questions equally well by means of serial vaginal cytology—and let him produce adequate vaginal cytological evidence to disprove our contention!

His belief is that the individual doctor should not be allowed to treat his patient with clomiphene unless the patient has been selected as suitable by, and unless the treatment is carried out under the supervision of, daily 24-hour urinary hormone assays. At least six years' intensive study both in the United States and in this country has been devoted to the clinical effects—and side-effects—of clomiphene. Both the Food and Drug Administration and the Dunlop Committee have agreed that it is sufficiently safe to be administered by gynaecologists and endocrinologists. No doubt it will be administered frequently to the wrong type of patient—it only induces ovulation and should therefore not logically be administered to a patient who is ovulating—but let us not have Dr. Kloppe and your leading article preventing us from using it unless our patients are prepared to become urinary prisoners of some rare laboratory.

This present correspondence applies in particular to clomiphene. It could equally apply in general to other drugs and other diagnostic investigations. I believe too much hospital time, too much public money, and too much interference with the routine of the patient's private life is being spent on many such investigations.—I am, etc.,

PETER BISHOP.

Chelsea Hospital for Women,
London S.W.3.

SIR,—The recent studies reported by Dr. D. Ferriman and others (25 November, p. 444) and Dr. E. Rabau and colleagues (p. 446) on the use of clomiphene therapy in the management of patients with infertility have stimulated me to present some preliminary results with low dosage oestrogen.

The patterns of follicle stimulating hormone and luteinizing hormone excretion in the normal menstrual cycle as reported by Stevens,^{1,2} in association with the usual oestrogen excretion pattern,³ together with the data observed following the use of oral contraceptives on gonadotrophin² and oestrogen/pregnanediol excretion,^{4,5} led to the theory that precise endogenous oestrogen production may be necessary to stimulate normal gonadotrophin secretion and the chain of events leading to ovulation.

After a discussion on the problems of infertility the hypothesis was further developed, and I suggested that such patients should be studied during oestrogen medication, the daily dose being determined by stepwise reduction every four weeks, the medication being prescribed daily for five to ten days. Each patient where possible was followed by

oestrogen and pregnanediol excretion. In some instances gonadotrophin excretion was determined. Very small doses of conjugated oestrogen (Premarin) gave encouraging results in a group of patients who had been followed most carefully. A number of these patients clearly ovulated, and in some instances pregnancy followed.⁶ Ethinyl oestradiol has also been used with some success in a dosage of 0.001 mg. That these small doses do stimulate F.S.H. secretion has recently been demonstrated by Stevens.⁷ At the recent World Congress of Obstetrics and Gynaecology, held in Sydney, McBride reported on the successful induction of ovulation in 12 of 18 women treated with 0.001 mg. of ethinyl oestradiol daily for 10 days. Although only four pregnancies were reported at the time the number has risen to eight.⁸

Clomiphene citrate is a non-steroidal com-

pound with both oestrogenic and antioestrogenic activity, but its precise mode of action in relation to ovulation stimulation is not clear. In view of the chemical similarity to chlorotrianisene (Tace) it is not unlikely that it may operate in a similar manner to very low dosages of Premarin or ethyl oestradiol.—I am, etc.,

Aylesbury, Bucks.

Nursing Services in General Practice

SIR,—I read with great interest the article on the above subject by Dr. J. Weston Smith and Mrs. E. M. Mottram (16 December, p. 672), and I would like to compliment them on the initiative and enterprise shown in meeting present-day problems in general practice. In all branches of medicine we need to look again at the established traditional ways of providing a service, particularly in view of the shortage of doctors in all three branches of the National Health Service. I would like to make a plea that the work of a nurse in a practice be undertaken by a fully trained district nurse attached to the practice. In a practice such as Dr. Smith's, the work could be undertaken by two nurses, one S.R.N. and one S.E.N., and this would include the work outlined in the article and the home-nursing and any treatment in the surgery.

The merit of this recommendation is that there would be no need to introduce another worker into the practice, which inevitably causes certain difficulties. The advantage of the attached district nurse undertaking practice duties is that she has a knowledge of, and direct access to other local authority health and welfare services—mental welfare officer, child care officers, home helps, medical loans, etc. This is particularly true of the district nurse with district training; and any other training to meet the particular needs of a practice can usually be arranged by the local authority.

In this county we have several district nurses, S.R.N. and S.E.N., attached to practices, and the scope of their work outside traditional district nursing is a matter that is left to the individual practice. The fear of interference by the local authority is much more imaginary than real, as details of working arrangements are fully discussed and agreed before attachment takes place. Not all doctors want district nurses attached to their practice, and not all district nurses are suitable for this work, but a great deal more can be done by experiment and trial to provide the nursing cover best suited to present-day general practice. We have found that where attachment schemes have been agreed better understanding and closer working relations have been established between general practitioners and nurses. It is the policy of this authority to foster attachment of district nurses to general practitioners, and I would be very willing to discuss such schemes with

any general practitioner in the county who is interested.—I am, etc.,

County Health Offices,
Mold, Flintshire.

G. W. ROBERTS.

SIR,—It would be a pity to allow the highly significant article by Dr. J. Weston Smith and Mrs. E. M. Mottram (16 December, p. 672) to pass without comment.

The National Health Service set out to provide medical treatment free at the time. Patients were left with the responsibility of deciding when a doctor was needed. Now, 20 years later, we are told they are not prepared to accept this responsibility but require a new service to advise them whether they need a doctor, to treat illnesses not serious enough to require a doctor, and to secure the provision of free medicine for these minor ailments.

Thus, a nurse was able to deal with over a third of first visits (requested before 10.30 a.m.) in a two-man partnership, and in only 67 out of 537 first visits did she find it necessary to ask a doctor to call subsequently (Table I of the article). She might recommend the doctor to prescribe "a simple cough linctus or antacid." Not only did the patients accept the arrangement, they began to ask for the nurse directly, and the "threshold at which a visit is requested has become lower." Dr. Weston Smith has dramatically extended the scope of the National Health Service. Without breaking the regulations, without an Act of Parliament, perhaps without even a word with the Minister, he has introduced a new service which will no doubt uncover further hidden needs. Others are doing the same by introducing, for example, organ transplantation. They will be competing with Dr. Weston Smith for the available public funds. For, although this article confirms that doctors all over the country are performing the duties of a nurse or wise grandmother at a time of medical manpower shortage, it does not offer the nurse as a solution. On the contrary, the doctors had the impression that, "far from lessening the amount of work done by doctors the amount of consultative work has actually increased."

Here, then, is a vivid illustration of the insatiable demand for medical care and of public readiness to abdicate personal responsibility in health matters. We can choose whether to extend the scope of the National

Health Service in the direction of serious illness and introduce charges for minor illness or whether to extend it in all directions at even lower standards. We can even choose to support Dr. Weston Smith's new service and pay through taxation. But, at a time when child poverty needs relief and old-age pensions are inadequate to provide both food and fuel, there is something seriously wrong with a system which can nevertheless provide an ever-increasing army of expensive social workers, doctors, and nurses to visit, console, and treat the victims.—I am, etc.,

Holywell,
Flintshire.

DAVID L. WILLIAMS.

Early Work with Blood Transfusion

SIR,—Sir Geoffrey Keynes (18 November, p. 410) refers to the tercentenary of blood transfusion. The idea of transferring blood from a healthy person to a sick one had been mooted long before 1667, and apparently attempts had been made to carry out transfusions. In 1492 Pope Innocent VIII died after receiving blood from three youths,¹ all of whom also died, so that it would seem to be a fair presumption that this transfusion was a massive one, and even if by some near miracle all three of the donor bloods were compatible with that of His Holiness the circulation must have been grossly overloaded.

My primary concern in referring to the article mentioned is to draw attention to the fact that in Dublin in the early eighteenth century there was at least one man interested in the possibility of carrying out intrahuman transfusion. This was Richard Pockrich (1695–1759). His own description of the process is nowhere to be found, but a presumably full account appears as a footnote to "The Projector," a "Poem in an Epistle to Richard Pockrich, Esq.," by the satirist Brockhill Newburgh.² Though this was published in 1769 it had apparently been written in 1743. Newburgh was related to his subject on the latter's distaff side.

As the description appears in this work it reads "Take an Inflex Tube in the Nature of a Scyphon, fix it at the extreme Ends in the Veins of two different Persons to be open'd to receive them, the one youthful, adult, and sanguine, the other aged, decrepid, and wither'd. . . . The redundant fermenting Blood of the one, will immediately flow like Wine decanted into the empty shrivel'd Veins of the other. The Effects will be found no less uncommon than surprising. The wither'd Skin Braces, the Flesh plumps up and softens, the Eyes sparkle, the Visage blooms, and the Blood is invigorated with new Supplies of vital Warmth. When the Blood or Spirits begin to fail, or any Symptoms of Mortality do approach, the Experiment is only to be repeated, and so on, with equal success *ad infinitum*. 'Tis a common practice in Housewifery, to renew strong stale Beer for twenty, thirty, or any other Number of Years. Why may not the Fluids of the human Body be renew'd in like Manner? 'Tis certain the Experiment has been try'd on other Animals with Success and if such creatures have happen'd afterwards to die, it has been wholly owing to the Neglect of the propos'd Discipline."

Pockrich apparently realized either that there were major difficulties or possibly never made any effort to carry out practical experiments, but he was so convinced that his blood-transfusion scheme could be successful that he proposed that a Bill be introduced in Parliament which would provide that a person could be legally declared dead when

he reached 999 years, and that among others the local clergyman might claim the fees he would normally receive for the burial service. Pockrich was a most remarkable rather off-beat character who produced visionary schemes which caused him to be referred to at a recent meeting of the Section of History in the Royal Irish Academy of Medicine in Ireland as a poor man's Leonardo da Vinci.

—I am, etc.,

Blackrock,
Dublin.

"Acrosclerosis"

SIR.—The recent article by Drs. A. W. Dellipiani and M. George (11 November, p. 334) on the syndrome of sclerodactyly, calcinosis, Raynaud's phenomenon, and telangiectasia, prompts us to report a further case.

A 75-year-old lady was admitted because of a hemiplegia due to cerebrovascular disease. She was noted to have tight shiny skin on some of her fingers, together with very rigid flexion deformities. Both thumbs showed dislocation of the distal interphalangeal joints. The tissues of the affected fingers were curiously hard and thickened. There were telangiectases on the lips,

FIG. 1.—Hand showing deformity and discharging area.

FIG. 2.—X-ray of hand.

face, and the palmar surface of the affected fingers.

Until the onset of the hemiplegia, which has been accompanied by severe dementia, she had been able to look after herself—including cooking, shopping, and doing housework—with some social support. History from friends and relatives gave no evidence of bleeding from the nose or gastrointestinal tract, nor was there any family history of bleeding. The patient had been troubled with Raynaud's phenomenon for as long as anyone could remember.

Later during her admission the skin of one of the affected fingers became inflamed and broke down, resulting in the discharge of a white pulsatious material, which on analysis proved to be composed of calcium and phosphate. The rest of the physical examination was not contributory.

Investigations revealed no definite evidence of involvement elsewhere, but the serum proteins were low at a total of 4.7 g./100 ml., with 3.4 g./100 ml. albumin, and 1.3 g./100 ml. globulin; electrophoresis showed a rather low γ and a high α_2 globulin. The white cell count persisted at a level of 20,000/cu. mm. and she has an iron deficiency anaemia with a haemoglobin of 7.6 g./100 ml. and a mean corpuscular haemoglobin concentration of 27%. However, these findings can be explained by the presence of a large bed-sore. X-ray of the hands showed extensive soft tissue calcification. There being no history or clinical evidence of dysphagia, a barium swallow did not seem justified in our patient. An electrocardiograph revealed nothing compatible with scleroderma.

This patient's history and progress support the contention that this syndrome has a benign course, but the deformities produced in our patient must have been at least to some degree incapacitating.

We are grateful to Dr. Harold Davis for his permission to publish details of this patient.

—We are, etc.,

STEPHANIE A. DAVIES.

Disinfectants and Plastic Mop Heads

SIR.—Prompted by the letters of Dr. D. A. Leigh and Miss Christine Whittaker (12 August, p. 435) and Dr. L. Steingold, Mr. L. J. Dunn, and Mr. S. Henman (2 September, p. 620) we have investigated the effect of polyvinyl acetate, polyurethane, and cellulose sponges on the germicidal activity of various phenolic disinfectants:

One-inch (2.5-cm.) cubes of the plastics were immersed in 50 ml. of the disinfectant solution; allowed to soak for 24 hours; then the solution, with plastic still immersed, was inoculated with 0.5 ml. of a culture of *Pseudomonas aeruginosa*. Reinoculation was made each day over a seven-day period, and 7½, 15, and 30 minutes after each inoculation a 0.1-ml. sample of the disinfectant was withdrawn and examined for surviving bacteria. Not more than 10 survivors from the 0.1-ml. sample at 30 minutes was regarded as a satisfactory result. Controls of disinfectant without plastic were satisfactory over the whole seven-day period even at the seven-and-a-half-minute sample.

Polyvinyl acetate had the greatest effect. At the normal dilutions of use none of the disinfectants retained activity for more than the first inoculation. Polyurethane had only slightly less effect than polyvinyl acetate, none of the disinfectants at their normal dilution of use surviving more than one or two inoculations. Cellulose sponge, however,

did not affect germicidal activity to any great extent, the use-dilutions of all the disinfectants being satisfactory during the complete seven-day inoculation period.

When the disinfectants were tested at one and a half to three times their normal use-dilutions against polyvinyl acetate and polyurethane activity was retained for periods ranging from two to seven days. We found some evidence that the plastics and disinfectants behave in different ways—for example, disinfectant A was less affected by polyvinyl acetate than disinfectant B, while with polyurethane the reverse occurred. We repeated the investigation with polyvinyl acetate and polyurethane, pre-soaking the sponge for 24 hours in disinfectant before transferring it into a fresh solution at the same concentration for testing. While interference with the germicidal activity could still be found it was much less severe than in the earlier investigation, all the disinfectants retaining activity at one to two times their normal use-dilution over the seven-day period.

It would appear that cellulose sponge is the plastic of choice to avoid loss of phenolic germicide from solution. With other sponge materials the problem can be overcome by pre-soaking (preferably in overstrength) disinfectant and/or changing the solutions frequently as a matter of good housekeeping.

Carcinogenicity of Tobacco and Tobacco Smoke

SIR.—Dr. M. Glass has asked two pertinent questions (5 August, p. 373), reiterated (9 December, p. 621), to which, he says, he has had no answer. I doubt if anyone can answer completely the vexed question of the pathogenesis of lung cancer in cigarette smokers, but the possibility that "some other essential factor, in addition to cigarette smoke," may be involved cannot be excluded. The important point is that in the absence of cigarette smoking, as opposed to smoke, to which non-smokers are often exposed, other possible factors that may be concerned in the evolution of cancer of the lung are less carcinogenic.

The absence of neoplastic reactions in the skin of the often heavily stained fingers of habitual chain-smokers may be related to the paucity, or absence, of pilosebaceous follicles in the lateral aspects of the fingers; assuming that the distillate from the tobacco contains fat-soluble potential carcinogens. There is experimental evidence from several independent sources which would support this explanation, which I reviewed in a different connexion.¹

The more difficult problem of the sequence of events in the pathogenesis of lung cancer in man, though unsolved, is not without clues. The demonstration² of basal cell hyperplasia and squamous metaplasia in the tracheobronchial tree in smokers, with or without lung cancer, as a more frequent finding than in non-smokers; and the observation³ that the increased incidence of primary lung cancer in smokers is practically limited to the epidermoid and undifferentiated

types suggests that these facts are causally related. Coughing, a regular accompaniment of smoking in many people, may be a contributory factor in the detachment of ciliated epithelium.

These may be some of the "other possible factors" postulated by Dr. Glass to which smokers are more liable than non-smokers.—I am, etc.,

Antibiotic Combination in Staphylococcal Infections

SIR,—A recent *in vitro* study¹ has shown the advantages of kanamycin and cephalothin or kanamycin and methicillin in combination against methicillin-resistant strains of *Staphylococcus aureus*. It was suggested that combination therapy be initiated against all methicillin-resistant strains while awaiting the outcome of the appropriate *in vitro* tests. Others have recently extended this recommendation and have suggested combination therapy in all serious staphylococcal infections even before it is known whether or not the infecting strain is methicillin-resistant.^{2,3} Before accepting this latter recommendation, especially since infections with methicillin-resistant strains are uncommon, it is important to know whether antagonism occurs when the combination is used against methicillin-sensitive strains of *Staph. aureus*.

Ten strains of methicillin-sensitive coagulase-positive *Staph. aureus* isolated from clinical specimens were used to investigate this possibility. Pure cultures were obtained by transfer of single-colony isolates. Routine disc sensitivity tests were done on all strains according to the method of Bauer and Kirby.⁴

Routine tube dilution minimal inhibitory tests (M.I.C.) were performed simultaneously, comparing kanamycin, cephalothin, and kanamycin/cephalothin. All tests were made of an inoculum of 10^7 organisms per ml. using tryptose-phosphate broth; tubes were read for macroscopic turbidity after 18 hours of incubation. Subcultures of 0.01 ml. of all clear tubes were made on to agar plates; the concentration of antibiotic which yielded no growth was considered to be the minimal bactericidal concentration (M.B.C.), although this test guarantees only that there are less than 10^3 survivors/ml. With two strains, dynamics of growth were studied

in the presence of antibiotics singly and in combination, with counts of colony-forming units made at 0 time, 1, 2, 4, and 24 hours. The rate of killing over the first four hours is thought to be particularly important in evaluating antibiotic combinations.⁵

The patterns of antibiotic resistance and the M.I.C. and M.B.C. are shown for all 10 strains in the Table. On the basis of minimal bactericidal concentrations, the combination was of some advantage in five cases, but in the others was only as effective as cephalothin used alone. Nine of the 10 strains were killed in 0.5 µg./ml. of each of the agents in combination.

Growth curve characteristics of strain 2576 are shown in the Figure and illustrate some synergism. The second strain tested in this fashion showed no difference in the rate of killing between the combination and cephalothin or methicillin used alone.

Against a large inoculum of a methicillin-sensitive strain of *Staphylococcus aureus*, the kanamycin/cephalothin combination, in concentrations easily attainable in the blood stream, shows greater bactericidal activity than either agent used alone.

In these studies of 10 methicillin-sensitive strains of *Staph. aureus* there were no evidences of antagonism. Since cephalothin and kanamycin are bactericidal in different ways, it would be predicted that there would be no antagonism and that synergism might occur.⁶

On the basis of these tests, it seems reasonable to consider using the kanamycin/cephalothin or kanamycin/methicillin combinations when confronted with a life-threatening staphylococcal infection. If disc tests show sensitivity to methicillin, the kanamycin may be stopped, although some experts prefer the combination in endocarditis, regardless of sensitivity to methicillin. If

the infecting strain is methicillin-resistant, the combination could be used until appropriate *in vitro* tests confirm its efficacy.—I am, etc.,

Dysmenorrhoea

SIR,—Mr. A. Davis (11 November, p. 357) supports Muir's hypothesis that dysmenorrhoea results from myometrial ischaemia due to hypercontraction of the uterus, but this view is not supported by the studies of Wilson and Kurzrok.¹ Severe ischaemia of the uterus often occurs during the early hours of the puerperium and is not associated with pain.^{2,3} Pain indistinguishable from dysmenorrhoea can be provoked in all women by means of chemical, mechanical, and electrical stimulation of the cervix uteri. A simple and precise method for measuring the critical electrical stimulus which when applied to the cervix causes pain was described in your columns.⁴ If these results are confirmed a foundation for dysmenorrhoea will be established.

A lowered threshold to pain arising in the uterus does not mean, as Mr. Davis suggests, that "it's all up here." He is well aware that but a small proportion of signals arising in the periphery reaches consciousness, for there are many "censors" in the nerve pathways concerned. The operation of these censors can be affected either way by impulses both from the higher centres and from the periphery. Further, the actual cells in the apperception area can similarly be affected. There is no need to stress the point that it is the destination of the signals which determines their message. Experimental studies^{5,6} show that the effects caused by stimulating the hypogastric nerve vary with the hormonal state of the subject.

Such a concept would explain why the same individual can have both painful and painless periods, the degrees of intensity of the pain, why women complaining of severe dysmenorrhoea may have painless periods when admitted to hospital for investigation, as well as the undoubted benefit derived from the varied and multitudinous methods of treatment, ranging from exercise, hygiene, and spinal manipulation to presacral neurectomy. It would also explain why any and all of these treatments may prove unavailing.—I am, etc.,

* Refers to antibiotics to which the strain is resistant on testing with high concentration discs according to the method of Bauer *et al.*⁴. Antibiotics tested were: Penicillin G (P), Erythromycin (E), Streptomycin (S), Chloramphenicol (Ch), Tetracycline (T), Kanamycin (K), Cephalothin (C), and Methicillin (M).

Improving the Psychiatric Services

SIR,—Being very interested in and committed to the task of trying to plan and provide suitable hospital services for elderly people, I think that Dr. H. Jacobs's letter (16 December, p. 681) calls for some comment.

I refer to the very popular notion of "x weeks in and x weeks out geriatric service." Such service is not necessarily the sort of panacea that many people seek. It is very difficult indeed to keep to any such timetable. One knows that shutting the elderly from here to there will in itself very often affect them adversely and one had found that at the end of the allocated stay in hospital the patient is much worse than at the time of admission. Although one is keen to help the relatives and benefactors of frail elderly people by giving them respite, and is able to do this in selected cases, I have come after many years to believe that the primary task of the geriatrician is to treat vigorously whichever patients have tractable diseases, tempering such treatment with, one hopes, humanity and common sense.

As for day hospitals, I am completely sold on their virtues and efficacy. I am beginning to think that these, paralleled by local authority day centres, might very well reduce dramatically the expense of providing in future for the needs of the elderly.—I am, etc.,

St. Edmund's Hospital, J. H. RAPHAEL.
Northampton.

Tetanus Prophylaxis

SIR,—I was very interested to read your leading article on tetanus prophylaxis (16 December, p. 635). I was pleased to see that you made it very clear that prophylaxis in the non-immune wounded patient for practical purposes rests between antibiotics and antitetanus serum. Neither of these has been proved to be 100% effective, but nevertheless clearly must be largely effective, for, as you state, the number of tetanus cases in this country is quite small.

I do wish, however, that you had made it very clear that tetanus toxoid has no practical value in the immediate prophylaxis of tetanus. We see a number of patients in this hospital who have had their initial treatment of wounds at a neighbouring hospital where the staff seem to be convinced that either tetanus toxoid alone, or tetanus toxoid plus one injection of penicillin, is adequate prophylaxis. At the recent symposium on tetanus held in Leeds in April,¹ which is referred to in your leading article, both Mr. Sharrard and I emphasized that a course of antibiotics was necessary for adequate prophylaxis. This point you have brought out in your leading article. Recently, however, my colleague Dr. J. J. L. Ablett lectured on the treatment of tetanus to a society some 40 miles from here. As a matter of interest, at the end of the lecture he inquired from all those present what method of prophylaxis they themselves used in the patient at risk. The majority of those present stated that they gave tetanus toxoid and one injection of penicillin. I am sure that Mr. Sharrard will join with me in condemning this as inadequate and in stressing once more that tetanus toxoid is of no immediate prophylactic value.

All except one of our last 10 patients undergoing treatment in our tetanus unit had

been given this form of prophylaxis, emphasizing its inadequacy from a different point of view.—I am, etc.,

Tetanus Unit,
General Infirmary,
Leeds.

M. ELLIS.

Low Back Pain

SIR,—I was interested in Dr. W. I. D. Scott's comments on back troubles in industrial and general practice (9 December, p. 618). I would agree with him that strict bed rest in simple lumbago is impractical. Indeed, I would suggest that it may be harmful in some patients by providing yet another somatic outlet for their psychological stresses.

After all, the acute prolapsed disc is rarely seen in general practice, and most cases of lumbago-sciatica fall into the category of musculo-ligamentous strains.

These cases respond admirably, in my experience, to infiltration with local anaesthetic solutions, with or without hydrocortisone, together with manipulation and early mobilization.—I am, etc.,

Elgin,
Morayshire.

A. M. BLAIN.

Bromism

SIR,—We should like to point out once more the dangers of the long-term administration of carbromal, especially as the amount prescribed may go somewhat unnoticed when it is combined with a hypnotic such as pentobarbitone as in Carbrital (carbromal 250 mg., pentobarbitone 100 mg.). The danger lies in the fact that bromide (to which most of the carbromal is metabolized) is much more slowly excreted from the body than pentobarbitone and therefore has a cumulative effect. A recent case illustrates this.

A 75-year-old man who had been taking Carbrital as a hypnotic for many years, and who possibly took more than his usual dose of two capsules four days prior to admission, was admitted in a very confused state with nystagmus, marked ataxia, and generalized diminution of sensation. His serum bromide level at this time

was 60 mg./100 ml. Without treatment this had fallen to 40 mg./100 ml. in five days and the above symptoms and signs had disappeared.

In the past nine years he has had five admissions to mental hospitals with episodes of confusion, delusions, and hallucinations. On each occasion these settled down without any specific treatment, within a few days of admission. A number of psychiatric diagnoses were suggested, but none were consistent with the transient nature of the symptoms.

As the serum bromide was not recorded during these admissions we have no definite proof that they were due to bromism, but in view of his recent illness and the well-documented evidence of psychiatric symptoms in bromide intoxication^{1,2} we consider that these were manifestations of a toxic level of bromide.

We would like to thank Dr. J. E. G. Pearson for his permission to report on this case.

Cause of Death

SIR,—Why in the obituary notices of doctors published in the *British Medical Journal* is the cause of death never stated? In the *Journal of the American Medical Association* it invariably is.

The American practice is, I suggest, more seemly. After all, the *British Medical Journal* is written by doctors for doctors, and deals mainly with disease and death; and it would be easy to make provision for that very small minority of deaths in which a public statement of the cause might distress relatives. Certainly a changed practice in this respect would have the incidental advantage of reminding us in a most direct way that we too are mortal. And lastly, one task of medicine is to discover and to set forth the truth, and reticence of the kind in question would seem to be at variance with it.—I am, etc.,

Little Missenden,
Amersham, Bucks.

S. BRADSHAW.

Hospital Management

SIR,—In your leading article (28 October, p. 187) you draw attention to the report on *The Shape of Hospital Management in 1980* by the King Edward's Hospital Fund.¹ The report of the joint working party set up by the Joint Consultants Committee and the Ministry of Health on the "Organization of Medical Work in Hospital"² has also just been published (4 November, p. 252). These two documents form an interesting comparison and deserve careful study by members of the medical profession who work in hospitals.

Considerable attention has rightly been given to the question of remuneration and to hospital buildings, but the administration of hospitals has tended to be considered of less importance. This, I think, is a mistake. Given a reasonable standard of remuneration and freedom from financial worry most doctors can put up with considerable difficulties as

regards their buildings, provided that the administration of the hospital satisfies them. In my view one of the causes of frustration and the so-called "brain drain" is the administration of hospitals. Members of the medical staff have difficulty in getting their views made plain and in getting their needs carried out efficiently, quickly, and economically. Although the consultant medical staff are not trained administrators they do have to make many decisions quickly and under difficult circumstances. It therefore causes them irritation when they see what appears to be quite a minor decision being shelved or wrongly made. Committee structure and multiplicity is often wrongly blamed for this when the trouble is the shortage of trained administrators of adequate calibre. Decisions are put off and shelter taken behind committee procedure.³ I would like at this point

to specifically exclude the administration of my own hospital group, for which I have a high regard.

There are certain issues that need to be clarified in the Joint Working Party's Report. The first and most important is the method of appointing the chief of staff, and the second is what his exact responsibility and powers would be. It would seem that they are really intended to be advisory. However, I think in the view of many this would not be sufficient. An executive committee needs executive powers and is not purely advisory. Economy can best be achieved by delegating the responsibility for estimates and budgets to the department head concerned. The question of the divisions needed would be a problem. In the development of hospital services many of the new specialties have already developed departmental set-ups with secretarial services. The older service specialties such as x-ray and pathology also have these arrangements. Anyone who has worked in a specialty which has a department with secretarial services and methods of keeping their own statistics knows how valuable this is and would be very loath to lose them to a broader divisional network.

Clarification is also needed about where the manpower, the secretarial services, and the space for them are going to come from. Unless these were very quickly provided this suggested administrative network would be doomed from the start. Consultants have suffered from lack of secretarial help for too long. Only recently has it been recognized that they should have secretaries of personal secretary grade. This is one of the reasons why I think they have given up many of the old administrative functions that they used to carry out and why hospital statistics and hospital activity research are not often done.

Business analogies should not be pursued too far where hospitals are concerned. The fundamental purpose of a hospital is to care for and to treat sick people. The consultant staff have the ultimate responsibility for ordering the expenditure of the very considerable sums that are now necessary to treat patients. To my mind, therefore, it is essential that the consultants should be able to take part in the management of hospitals at the highest level. They need to be involved in more than an advisory capacity and be given both executive and financial responsibility. There are many difficulties to be ironed out, but, given the sympathy and support of the consultants and proper secretarial backing, I think the suggestions of the Joint Working Party would be a great start towards a more efficient and human administration of hospitals. It is to be hoped that the Joint Working Party will consider the total administration of hospitals in addition to the medical side, as it would seem to me, from the point of view of the medical staff, an alternative to the present situation, and the "Shape of Hospital Management in 1980" is badly needed.—I am, etc.,

Bury St. Edmunds,
Suffolk.

J. WEDGWOOD.

SIR,—It is sad to note in the letter written by Mr. J. Blundell and Dr. J. Lowry (9 December, p. 617), regarding the subject of managing the hospitals, that they confuse opinion with fact in dealing with the hoary old chestnut of the takeover of the running of the hospital by lay administrators.

As a member of the King's Fund and Institute of Hospital Administrators Working Party on *The Shape of Hospital Management in 1980* I bore certain responsibility for the issue of its report.¹ I have a copy before me as I write, and it is very clear that the general manager envisaged would, without question, be the best manager available, whether medical, lay, or nursing, or from other sources. The report made it quite clear that the manager could be a doctor, nurse, or lay administrator with the appropriate management attributes—these are the facts.

Taking this further the report itself stresses that all persons, medical, nursing, and administrative, who in future would hold managerial appointments in the hospitals should have received both training and experience in management and management needs to be able to measure performance. It also provides training posts for this to be achieved in each sphere of activity. Good management must be done and be seen to be done in the future so that we may run our hospitals more efficiently for the benefit of our patients as well as the satisfaction of the staff.—I am, etc.,

Approval of Emergency Treatment Service

SIR,—Dr. W. P. Fitt (9 December, p. 623) questions the need for the Emergency Treatment Service in a well-organized general-practitioner service. Since he suggests that a four- or five-partnership rota is desirable, why not also the next logical step of an efficiently organized larger rota, the Emergency Treatment Service, particularly as it has been proved successful in practice?

The other question, "Are doctors really happy about State-registered nurses answering the phone?" would be answered with an emphatic "yes" by those of us lucky enough to have had the chance to use such a service. It is certainly to be preferred to the previous alternatives, ranging from non-medical secretaries to au pair girls. But perhaps of greater importance than the satisfaction of the subscribing doctors to the Emergency Treatment Service is its acceptability and indeed popularity with the patients whom it serves.—I am, etc.,

St. George Health Centre,
Bristol 5.

A. DOWLING.

service "in keeping with the traditions of our profession."

Let us look at some facts. An analysis of my patient contacts in the past month has shown that less than 4% of my patients seen at home and 0.8% of total patient contacts were by an Emergency Treatment Service doctor. My off-duty, however, has been increased by 48 hours per week over what it was in our three-doctor practice prior to using the Emergency Treatment Service. It has been our experience that patients urgently requiring medical aid wish in the first place their own doctor, but if he is not available then they do not care particularly if it is one of a large group practice or another doctor provided he copes adequately with the situation, and provided he arrives promptly. Dr. Fitt talks about increasing efficiency. Is it more or less efficient to have nine doctors actually working with two-way radios in their cars so that always at least one is available for an urgent call, or to have 200 doctors tied to the phone or on call from the golf course? As for his point about nurses answering the phone, a ring round his colleagues will show that it is much more likely that the phone will be answered by the doctor's wife, an unqualified receptionist, or a Robophone than the doctor himself.

I am firmly in support of the value of a personal doctor, but his real value is in coping not with an acute appendix but with medical, emotional, and social problems of a more long-term nature. To cope adequately with these it is essential in the long term to have adequate time off call, and this can be done by allowing an efficiently run deputizing service like E.T.S. to cover urgent out-of-hours calls.—I am, etc.,

Bearsden,
Glasgow.

KENNETH HARDEN.

Points from Letters

Casualty Staffing

Mr. J. W. WILSON (Belfast City Hospital) writes: It appears from the report of the proceedings of the Central Committee for Hospital Medical Services (4 November, *Supplement*, p. 36), and the more recent letter of Mr. G. Rigby-Jones (11 November, p. 360), that the staffing of casualty departments is again the subject of interest, if not possibly of the anxiety that it merits. This problem is not one that can be dealt with in isolation; decisions taken here affect the whole hospital beneficially or adversely. The whole question of the department's responsibilities to the public, and equally to its nursing and medical staffs as regards teaching and career possibilities, must be fully appreciated before any acceptable decision on its staffing can be made. . . . It is to be hoped that when the Central Committee for Hospital Medical Services sets up its subcommittee to study this question it will seek the advice of, or, better, co-opt, consultants with wide experience in this very important hospital department.

Anaphylactic Reaction and Soap Enema

Dr. TORGILS AANELAND (Bærum, Norway) writes: In the very interesting article by Dr. Donald Smith (28 October, p. 215) there is no information about former contact between the patient and the "proprietary brand of soap-flakes," or a similar one. As long as this important information is lacking the soap allergy will continue to be a "foggy" problem in the future too.

SIR,—It is interesting to note that in the opinion of Dr. W. P. Fitt (9 December, p. 623) I, along with over half the general practitioners in Glasgow, belong to a service (the E.T.S.) of which there is need, and also by so belonging we are failing to provide a

Obituary Notices.

G. L. ROBERTS, M.B., CH.B., B.D.S., F.D.S. R.C.S., F.F.D. R.C.S.I.

Professor G. L. Roberts, for 32 years professor of dental surgery and director of dental studies at the University of Sheffield, died suddenly in his office at the Charles Clifford Dental Hospital on 14 December. He was 63.

George Laurence Roberts was born on 14 January 1904, and received his medical education at the University of Liverpool, where he had a distinguished career as both

a medical and dental student. He graduated M.B., Ch.B. with honours and a distinction in surgery in 1927. In 1928 he was successful in obtaining the degree of Bachelor of Dental Surgery with first-class honours. He held teaching posts in the universities of Liverpool, Leeds,

and Birmingham before being appointed to the chair of dental surgery in 1935.

Laurie Roberts started his work in Sheffield in a very tiny dental school which was housed mainly in a small part of the Sheffield Royal Hospital. He immediately persuaded the university and hospital authorities to build a new dental school. This was about to be done, when the second world war postponed the building indefinitely. Although deeply disappointed, Roberts, with a handful of loyal general practitioners and one full-time lecturer, developed the teaching to a standard which compared well with other schools in Great Britain. After the war he supervised the planning of the new school, and was responsible more than any single person for its coming into being. One of the proudest days of his life was in 1953, when the Charles Clifford Dental Hospital was opened by the Duchess of Gloucester. Although the new building appeared at first to be much too large for the requirements of a small dental school, Laurie Roberts had so built up its strength and students by 1964 that considerable additions, in the form of a new floor and extra laboratories and facilities for staff, were added. Again these improvements would not have been possible but for his skill in persuading others of the need and desirability of the extensions.

Professor Roberts was not only active in his own university, where his great experience enabled him to express views which were always listened to with respect, but was a great force in the wider world of dentistry. He was a leader in the Faculty of Dental Surgery of the Royal College of Surgeons of England, of which he was vice-dean in the session 1963-4, and member of the General Dental Council and the chairman of many important committees concerned with the affairs of the Council. He was consultant

adviser in dental surgery to the Ministry of Health, and adviser on dental health to the World Health Organization.

Laurie Roberts was always anxious to have what he used to refer to as a happy ship. He was, like all great captains, able to inspire his staff and to gain their respect by his obvious sense of "service." All who knew him were certain that all his actions and thoughts were concerned only with the advancement and improvement of his dental school and his profession. He gave all he had to his profession,

V. H. J. DAVIES, M.D., F.R.C.S.ED., D.OBST.R.C.O.G.

Mr. V. H. J. Davies, formerly senior consultant gynaecologist and obstetrician to the Swansea and Morriston Hospitals, died suddenly in his consulting-rooms on 15 December. He was 66.

Vyvyan Henry Jeremy Davies was born in Landore, Swansea, on 17 July 1901. He received his early education at the Swansea Grammar School, and from there pursued his medical studies at Charing Cross Hospital, London. He took the Conjoint diploma in 1924, and after holding posts as house-physician and resident obstetric officer at Charing Cross Hospital, he became resident medical officer at Queen Charlotte's Hospital. He settled in general practice in Swansea in 1927, and in the same year married Dr. Margaret Hughes Brown, who had been a contemporary of his at Charing Cross. He soon became established and built up a large practice. In 1932 he was appointed honorary anaesthetist at Swansea Hospital, and in 1935 police surgeon to the county borough. In 1934 he took the D.Obst.R.C.O.G. and in 1935 graduated M.B., B.S., proceeding to M.D. in 1937 with midwifery and gynaecology as his special subjects. In 1943 he became F.R.C.S.(Ed.), and thereafter his course was set. He left general practice and resigned from all his other appointments in 1946, when he became honorary consultant gynaecologist to Swansea and Gorseinon Hospitals. In 1948 he was appointed consultant gynaecologist to the Gwent Hospital Management Committee Group, a post he retained until his retirement in September 1966. He was consultant obstetrician to the county borough of Swansea, and in that capacity played a considerable part in the establishment of the "flying squad," and was also obstetric adviser to the local branch of the Family Planning Association.

He took an active interest in all local medical affairs, and was chairman of the Swansea Division of the British Medical Association from 1942 to 1945. Subsequently he was a member of the Gwent Hospital Management Committee for six years, chairman of the medical staffs committee, and also chairman of the Swansea and Morriston Hospitals standing medical committees. In 1967 he was made a Fellow of the British Medical Association, an honour of which he

to which he added dignity and integrity. He was fortunate in living at a time when great advances were taking place in dentistry. Few have done more to bring about these changes than he.

Whenever the story of G. L. Roberts's achievements is told the support and help given to him by his wife, Joyce, will never be forgotten. Without her patient help and support it would have been impossible for him to live the busy life his work demanded. To his wife and two sons, David and Alex, we extend our deepest sympathy. —E. L. H.

was very proud, and which was singularly well merited.

Vyvyan Davies was an eminent doctor and general practitioner, but undoubtedly he found his greatest fulfilment as a gynaecologist and obstetrician. Possessed of an able, keen, and analytical mind, he was an astute clinician and first-class diagnostician. As a surgeon he was careful, painstaking, dextrous, and very gentle. His years in general practice made him very approachable, and he was ever mindful of the difficulties of his general-practitioner colleagues, and always ready to be of service to them and their patients. He took a great interest in his junior hospital staff, and it is worthy of note that five of his former senior registrars now hold consultant posts. In committees he did not speak much, but when he did he was pertinent and to the point, and his opinion always carried great weight.

He had very little time to devote to hobbies. Always a great family man, he loved having his wife and children with him, and took great pride in his 10 grandchildren. Golf was his main recreation, and he had been a member of Pennard Golf Club for many years. In his day he was no mean performer and a doughty opponent. In May 1967 he had a major operation, and, although he was desperately ill for several days, he was most courageous and eventually made a good recovery. He died suddenly in his consulting-room while seeing one of his old patients, and it was a tragic coincidence that his death should have occurred on the same day that the old Swansea Hospital closed down—the place where he had done so much work during the past 40 years. Thus ended a life full of purpose, endeavour, and achievement, and his departure from the scene will leave a gap in the community of Swansea and its environs which will not easily be filled. He will be mourned and missed by many, particularly by those of us who had known him so well and worked with him over the years. It has been a great privilege to have enjoyed his friendship, his companionship, and his confidence.

He is survived by his wife, Dr. Margaret Davies, two sons, and one daughter, and to them we extend our deep sympathy. —C. H. D.

**C. R. WHITTAKER, F.R.C.S.ED.
F.R.S.ED.**

Dr. C. R. Whittaker, a former lecturer on anatomy at the School of Medicine of the Royal Colleges, Edinburgh, died on 4 December. He was 88.

Charles Richard Whittaker, a Lancashire man, took the triple qualification of the Royal Scottish Corporations in 1904, and was admitted a Fellow of the Royal College of Surgeons of Edinburgh in 1907. He devoted his life to teaching. In his early days this took the form of coaching, and his revision classes in anatomy and surgery for undergraduates and postgraduates working for their Fellowship were extremely popular, spiced as they were with witty and imaginative touches which served to fix the facts in the minds of his hearers. He busied himself also with writing, and was the author of *Surface Anatomy*, which went into three editions, *A Manual of Surgical Anatomy, Nerves of the Human Body*, and *An X-ray Atlas of Normal and Abnormal Structures of the Body*.

Extramural teaching in Edinburgh has now ceased, but it has a long and honourable history. This was especially true of anatomy. When Whittaker qualified the teaching of anatomy extra-academically was in the safe hands of a fellow Lancastrian and, curiously enough, a namesake, Joseph Ryland Whitaker, a notable teacher whose vacation courses drew large numbers from south of the border. Charles was Ryland's deputy, and the apprenticeship was a lengthy one, for it was not until 1931 that he succeeded as senior lecturer. He worthily maintained the tradition. A member of the British Medical Association, he was vice-president of the section of anatomy and anthropology at the Annual Meeting in 1939.

Among his outside interests painting was pre-eminent. It took him to several European countries, and resulted in the acquisition of a considerable art library. He found congenial company in the Scottish Arts Club, of which he later became president. He held office in the Scottish Society of Artists and the Scottish Artists' Benevolent Association. A number of his own works, in the abstract idiom, were hung in the annual exhibitions of the Royal Scottish Academy. In 1950 he was elected to honorary membership of the R.S.A. and appointed honorary professor of anatomy, an office which dates back to the days when that institution had its own life classes, and which had long been in abeyance. This appreciation by artistic circles in the capital gave him much pleasure and helped to fill a void in his life created by the death of his wife and only son.

Charles Whittaker did not wear his heart on his sleeve, but he was warm-hearted and generous and he was a good friend to generations of students, many from distant parts.—W. A. A.

**G. HAMILTON, M.A., M.B., B.CH.
B.A.O., D.A.**

Dr. G. Hamilton, formerly consulting anaesthetist to the Northern Ireland Hospital Authority, died on 7 December at the age of 80.

George Hamilton was born on 7 March 1887. He took up medicine after a business career and engaging in parish work. Having

graduated at Trinity College, Dublin, he entered the School of Divinity and served in the parish of Mohill, Co. Leitrim. He was there during the time of the "troubles" and had many harrowing experiences. Later he worked in the parishes of Dundonald and Killinchy. He then decided to embark on the study of medicine and he became a student at the Queen's University of Belfast, where he graduated M.B., B.Ch., B.A.O. in 1927. He set up in practice in Belfast, combining general practice with hospital work, and was for several years a clinical assistant in the ear, nose, and throat department of the Royal Belfast Hospital for Sick Children. He distinguished himself in the field of anaesthetics, and worked for many years in the Royal Belfast Hospital for Sick Children and the Royal Victoria Hospital. When the Health Service began he was appointed a consultant anaesthetist to the Hospitals Authority. He was honoured in 1947 by being elected to the Diploma of Anaesthetics of the Royal College of Surgeons in Ireland. His wide interest in medicine also embraced the field of occupational medicine, and he was for many years medical officer to Messrs. James Mackie & Sons Ltd., and to the Great Northern Railway. He was an active member and fellow of the Ulster Medical Society, and was at one time a member of its Council. He had also served on the executive committee of the Belfast Division of the British Medical Association. He continued his lifelong interest in church matters while practising as a doctor.

He is survived by his wife, Irene, and son, Trevor, who carries on the medical practice in Belfast.—G. T. C. H.

**H. C. JENNINGS, M.A., M.B., B.S.
D.P.H.**

Dr. H. C. Jennings, formerly county medical officer for Oxfordshire, died at his home in Eastbourne on 19 November. He was 74.

Henry Cecil Jennings was born on 6 January 1893, and received his medical education at Oxford University and St. Thomas's Hospital, where he qualified with the Conjoint diploma in 1915 and graduated M.B., B.S. two years later. During the first world war he served in the Royal Navy, and after demobilization decided to take up a career in public health work, taking the D.P.H. in 1920. After service with the Leeds City Council he became medical officer for the Holland Division of Lincolnshire, and then went on to take up his appointment as county medical officer for Oxfordshire, an appointment he held for 21 years. In 1935 he took the B.Sc. and B.A. with honours in natural science, and four years later proceeded M.A. He was an examiner in public health at Oxford University, and a Fellow of the Society of Medical Officers of Health. A member of the British Medical Association, he was chairman of the Holland Division in 1928-9. In the second world war he served as colonel in the Home Guard. After his retirement in 1953 he accepted the appointment of chairman of the Banbury Hospital Management Committee. In this capacity he undertook his responsibilities with great thoroughness, making himself familiar with every aspect of hospital administration and never hesitating to say what he thought at committee meetings. In 1964

he moved to Eastbourne, where his former colleagues were always very pleased to see him and to renew their happy associations with a man who was always friendly and a very good companion.

While he was at Oxford Henry Cecil Jennings took a great interest in the university and maintained an active membership of the Union. He was the first chairman of the Oxford Medical Officers of Health Liaison Committee, and it is to his credit that such a happy relationship has always existed between the public health and hospital board staff in the Oxford region. In addition to his academic pursuits he was very interested in all forms of sport. He himself was a good golfer and a keen follower of university cricket and rugby. Not infrequently he was to be seen in the Parks or at Ilfley Road, following the game with a sure eye for its finer points. He was an excellent raconteur with a good sense of humour, and was never at a loss to illustrate a point with a story or incident. All who knew him will enjoy warm memories of his companionship, and will wish to extend their very sincere sympathy to his wife and two daughters who survive him.—M. J. P.

N. J. E. writes: Dr. Jennings will be remembered for his championship of the use of general practitioners in the public health service. He made full use of their services in preference to appointing whole-time staff. The strain of the war years was to justify his good judgement in that an adequate public health service was well maintained. His insistence that the general practitioner must be a key figure in the public health service led to a much wider use, in the post-war years, of the health visitors by the general practitioners. This in its turn led to the establishment of a health-visitor school in Oxfordshire. He was a keen member of the County Medical Officers of Health Society and a past chairman.

**W. R. SADLER, L.R.C.P.ED., L.R.C.S.ED.
L.R.F.P.S.GLASG.**

Dr. W. R. Sadler, a general practitioner in the east end of Glasgow, died at his home on 5 December. He was 62.

William Ross Sadler was born on 20 April 1905, and spent a number of years in the family business in Glasgow before deciding, in his middle thirties, to embark on a medical career. He took the Scottish triple qualification in 1945 at the age of 40. After spending a year as an assistant at Thornliebank, he went to a country practice at Barnhill in Ayrshire for two years; then he moved to a practice in the Shettleston district of Glasgow, where he served his patients faithfully for 19 years until his death. He was a member of the Glasgow Local Medical Committee for 15 years until failing health necessitated his resignation. Before entering medicine he was interested in the Masonic movement, in which he held high office. For almost all of his professional life in Glasgow he was an elder in Shettleston Old Parish Church. He was a very able physician with an alert mind and sound judgement, and a man of personal integrity beyond question.

To his wife, his two sons, and two daughters we extend our deepest sympathy.—J. G. W. C.

News and Notes

EPIDEMIOLOGY

Hospital Inpatients

The publication by the Ministry of Health and the General Register Office of the Commentary completes the report on the hospital inpatient inquiry in England and Wales for the two years 1960 and 1961. The data were based on a 10% sample of inpatients in all N.H.S. hospitals. Mental hospitals and mental deficiency hospitals were excluded; they have been reported on separately. Patients in psychiatric departments of general hospitals and private patients were also excluded.

The report is divided into six main sections: (1) geographical variations, (2) administrative and general aspects, (3) diseases by system, (4) maternity patients, (5) surgical operations and investigations, and (6) occupation.

Variations between regions were considerable. The rate of admission was highest in the Liverpool region in 1961, with 93 per 1,000 population, and lowest in East Anglia in 1960, with 64 per 1,000 population. High 1961 rates were recorded in the N.W. and N.E. Metropolitan regions, 92 and 90, respectively. Low 1961-2 rates were

recorded in Sheffield, 68 and 67. Average duration of stay in hospital ranged from 22 days in the Liverpool region during 1960 to 16 days in the Newcastle region in 1961. For the whole country the admission rate for non-maternity beds was 39 per 1,000 population and for maternity beds 3.8. The hospitals in rural areas had a smaller admission rate than in urban areas, but there is no consistent trend between towns of varying size.

Females had a greater rate of bed occupancy than males even after excluding maternity cases. Average duration of stay was lower for females from ages 15 to 64 but higher after age 65, rising to about 50% above the male rate at ages 85 and over.

The largest number of admissions for children up to age 14 were for tonsils and adenoids, 17,359; appendicitis, 3,627; head injuries, 2,549; other fractures, dislocations, injuries, and reactions to treatment, 3,789; other infectious and parasitic diseases 2,170; pneumonia, 2,083; strabismus, 2,028. Malignant neoplasms caused an admission rate of 44.0 per 1,000 in 1961. The sites with large rates were: digestive system, 8.0; lung, 7.5; and breast, 5.6. The admission rate for cancer of the lung in London was

10.9, compared with the national average of 6.7.

The average number of available maternity beds rose from 19,410 in 1959 to 20,004 in 1961. During this period the percentage of hospital deliveries steadily increased, 60.4 in 1959, 61.2 in 1960, and 62.7 in 1961. The average duration of postnatal stay fell continuously from 10.0 days in 1957 to 8.4 days in 1961. For the same period the percentage discharged on or before the seventh day rose from 12.5 to 27.9.

The number of operations performed in hospitals in this inquiry during 1961, apart from those performed in maternity units, was almost 1½ million. Gastrointestinal and abdominal surgery accounted for one-quarter of all operations. For males aged 16 years and over the data have been tabulated by occupation and shown by age, duration of stay, and deaths in hospital. The rates of admission to hospital vary with occupation, and the composition of the occupational group varies with age. For these reasons the rates have been standardized. Miners and quarrymen had the largest admission rates in each age group up to age 55.—*Report on Hospital In-patient Inquiry for the Two*

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending 9 December (No. 9) and corresponding week 1966.

Figures of cases are for the countries shown and for Greater London. Figures of deaths and births are for the whole of England and Wales (London included), Greater London, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

Tees-side Gastroenteritis

Gastroenteritis in recent weeks among babies under 1 year had caused 37 cases on Tees-side by 22 December, when we went to press. Eight babies have died, but the infection was not the direct cause of death in four of them. Eight babies are still dangerously ill. The infecting organisms were *Escherichia coli* 0128 (the more dangerous) and *E. coli* 0119.

The infection began some weeks ago with a case at West Lane (Infectious Diseases) Hospital, Middlesbrough. The infection spread from there when babies were transferred to the Stockton Children's Hospital and the Middlesbrough General Hospital.

Eire in Third Quarter

The birth rate in Eire during the third quarter of 1967 was 21.2 per 1,000 of the population, and was 0.9 below the rate for the third quarter of 1966. The infant mortality rate was 23 and the neonatal mortality was 15 per 1,000 registered births; these were the same and one less, respectively, than the rates for the corresponding quarter of 1966.

Deaths from the principal infectious diseases included 35 from gastroenteritis under 2 years, eight from influenza, three from whooping-cough, two from acute infectious encephalitis, one from diphtheria, and one from measles. Deaths from tuberculosis

were 35 from the respiratory form and 13 from other forms, and these were 21 fewer and four more, respectively, than the preceding third quarter. Of the 1,279 deaths assigned to malignant neoplasms 588 were due to those of the digestive system and 219 to those of the respiratory system. The general death rate was 9.9 per 1,000 population, being the same as the rate for the September quarter of 1966.

MEDICAL NEWS

Universities Collaborate in Medical Education

The universities at St. Andrews and Manchester have agreed to co-operate in medical education. A joint liaison committee will operate the scheme, which it is hoped will include interchange of staff.

From 1973 onwards the enlarged clinical school in Manchester University will draw its students from the preclinical schools in both Manchester and St. Andrews. Students at St. Andrews will study for three years in the faculty of science on an extended pre-clinical course and will take a B.Sc. ordinary degree, or an honours B.Sc. with an extra year of study. Those wishing to qualify in medicine will be able to go to Manchester for three more years' work leading to the M.B., Ch.B. degrees. The partnership will make it possible to provide for a wider range of applicants drawn from both England and Scotland. For many it will also be an advantage to spend part of their time in a relatively small and closely knit community and the rest in a large civic university.

Manchester will continue to expand its pre-clinical as well as its clinical capacity in accordance with Government policy. An enlarged clinical school is now being developed. The university will retain its close association with the United Manchester Hospitals and form a new association with the

regional hospital board, notably at Withington Hospital, which will become a full teaching hospital.

The scheme, it is claimed, represents a considerable contribution to the national need to increase the supply of doctors and does so cheaply by making full use of resources and skills already in existence.

New Health Centres at Oxford

Opening two health centres in Oxford on 14 December, the Minister of Health, Mr. KENNETH ROBINSON, predicted that more than 100 health centres were likely to be in use in England and Wales within the next three years. "And four or five times that number within 10 years," he added. Oxford, he said, was the first county borough in England to have three operational health centres. In achieving as well 100% attachment of its nursing staff it had set an example to the rest of the country.

Population Census in 1971

The MINISTER OF HEALTH stated in a written reply on 18 December that the Government had decided to seek the authority of Parliament to take the next census in April 1971. It will mean "a full enumeration of the whole population." Preliminary tests on a voluntary basis will be carried out to ensure the efficiency of the operation. These will include a test census next April in 10 selected areas in England and Wales and 10 in Scotland.

Appointments to Professorships

The title of professor of neurosurgery has been conferred on Mr. VALENTINE LOGUE in respect of his post at the Institute of Neurology. Mr. Valentine Logue was educated

at Bishop's Stortford College and King's College, London, and graduated from St. George's Hospital in 1936. After four years in general surgery, during which time he was elected to the temporary wartime consultant staff of St. George's, he

transferred to neurosurgery in 1942, subsequently serving in the R.A.M.C. as neurosurgical specialist. In 1948 he was appointed neurological surgeon to the Maida Vale Hospital for Nervous Diseases and St. George's Hospital, and in 1957 he left to join the staff of the Middlesex Hospital. In 1965 he took the post of director of the newly established department of neurosurgical studies at the Maida Vale and National Hospitals for Nervous Diseases. Mr. Logue's interests are centred particularly around spontaneous intracranial haemorrhage and also the surgery of the spine and spinal cord. His published work includes articles

on the treatment of ruptured posterior fossa aneurysms and intermittent claudication of the cauda equina.

Dr. L. B. STRANG has had the title of professor of paediatrics conferred on him in respect of his post at University College Hospital Medical School. Dr. Strang, who is 42, was educated at the Royal Grammar School, Newcastle upon Tyne, and University of Durham, graduating M.B., B.S. in 1949. After holding junior house appointments at

the Royal Victoria Infirmary he became first assistant in the Department of Child Health in the University of Durham in 1956. In 1959 he obtained an M.R.C. research fellowship, and spent two years at Hammersmith Hospital in the department of medicine. From 1961 to 1962 he

Julia Bennett Studios

was research fellow at Harvard Medical School, and he then returned to Hammersmith as senior lecturer and consultant in the department of child health. He took up his appointment at U.C.H. in 1963. Dr. Strang obtained his M.D. with distinction in 1961 and he was elected F.R.C.P. this year. His publications in the clinical field include the original descriptions of the Harlequin syndrome, the secretion of catecholamines by neuroblastomas, and the existence of right to left shunts in infants with respiratory distress. In the past five years his main research work has used the foetal lamb preparation to study the adaptive change which takes place in the foetal lungs at birth. It has dealt with the control of pulmonary blood flow, the surface properties of the developing lung, and lymph flow from the lungs.

The title of professor of forensic medicine has been conferred on Dr. DONALD TEARE in respect of his post at St. George's Hospital Medical School. Dr. Donald Teare was educated at King William's College, Isle of Man, and Caius College, Cambridge. He qualified M.R.C.S., L.R.C.P. in 1936.

In 1937 he obtained the M.B., Ch.B. and the M.R.C.P. From 1938 to 1946 he was assistant curator of the museum at St. George's, his appointment being interrupted for a year when he was pathologist in the Emergency Medical

Service. In 1946 he was appointed pathologist to the hospital and lecturer in forensic medicine at the medical school and at St. Bartholomew's Hospital Medical College. He was elected a Fellow of the Royal

College of Physicians in 1962. The same year he was awarded the diploma in medical jurisprudence by the Society of Apothecaries of London. In 1963 he became a Founder Fellow of the College of Pathologists and reader in forensic medicine at St. George's. He was elected president of the Medical Defence Union in 1964.

People in the News

► Mr. KENNETH WYBAR has been appointed as Civilian Consultant in Ophthalmology to the Royal Navy.

News in Brief

From 1 January births in Wales and Monmouthshire may be registered in Welsh as well as in English.

Grants and Awards

A £12,000 research grant has been awarded to the Institute of Directors' Medical Centre by the British Heart Foundation. It will be used partly to finance a project to investigate the life expectancy of businessmen.

Coming Events

Medicine Today (B.B.C. T.V. programmes).—"Foetal Growth" (Dr. F. BRIMBLECOMBE and Mr. H. GORDON), 2 January, 1.15 p.m., transmitted on B.B.C. 2. Repeated on B.B.C. 1, 10 January, approximately 11 p.m.

Lister Centenary.—The exhibition at the symposium on "Operating-rooms a Century after Lister," arranged by the B.M.A. to commemorate the Lister centenary, will be on view in the Great Hall at B.M.A. House until 5 January (open 9 a.m. to 6 p.m.).

Hospital Physicists' Association and Urological Section of the Royal Society of Medicine.—Conference, "The Use of Electrical Stimulation in Urinary Retention and Incontinence," 12 January, 10.30 a.m., Royal Society of Medicine. Details from General Secretary, Hospital Physicists' Association, Tavistock House North, Tavistock Square, London W.C.1.

Societies and Lectures

For attending lectures marked ● a fee is charged or a ticket is required. Applications should be made first to the institution concerned.

Monday, 1 January

CHELMSFORD MEDICAL EDUCATION AND RESEARCH TRUST.—At Chelmsford Medical Academic Unit, Chelmsford and Essex Hospital, 5.30 p.m., clinical meeting.

INSTITUTE OF LARYNGOLOGY AND OTOLGY.—5.30 p.m., Professor I. Friedmann, Dr. D. A. Osborn, Dr. M. I. Wright: clinicopathological conference.

SOCIETY FOR MEDICAL AND DENTAL HYPNOSIS.—At Royal Society of Medicine, 8 p.m.; dental meeting.

Tuesday, 2 January

B.B.C. 2 TELEVISION.—1.15 p.m., *Medicine Today: Foetal Growth*. (Sponsored by A.S.M.E.)

BOLTON AND DISTRICT MEDICAL SOCIETY.—At Gymnasium, Bolton Royal Infirmary, 8.15 p.m., Dr. G. M. Berlyne: Haemodialysis.

ST. CHARLES'S HOSPITAL MEDICAL CENTRE.—8.45 p.m., Dr. A. I. Suchett-Kaye: Some Topics of Interest in Geriatrics.

Wednesday, 3 January

CHELMSFORD MEDICAL EDUCATION AND RESEARCH TRUST.—At Chelmsford Medical Academic Unit, Chelmsford and Essex Hospital, 12 noon, surgical meeting.

STOKE MANDEVILLE HOSPITAL.—12.15 p.m., Dr. Lorna Davies: clinical cases.

Thursday, 4 January

EMERGENCY MEDICAL AID COMMITTEE FOR ISRAEL in conjunction with the BRITISH FELLOWSHIP OF THE

ISRAEL MEDICAL ASSOCIATION.—At the Medical Society of London, 11 Chandos Street, London W.1, 8.15 p.m., Professor Harold Ellis: Post-graduate Medical Education in Israel.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m., Hunterian lecture by Professor J. P. Reidy: The Nasal Septum.

Friday, 5 January

BIOCHEMICAL SOCIETY.—At Department of Biochemistry and Chemistry, St. Bartholomew's Hospital Medical College, 9.30 a.m., colloquium on Properties of Enzymes Attached to Solid Matrices, followed in afternoon by ordinary meeting.

Saturday, 6 January

ROYAL POSTGRADUATE MEDICAL SCHOOL.—9.30 a.m., anaesthetic teaching meeting: Overdose with Therapeutic Agents.

Sunday, 7 January

EDGWARE POSTGRADUATE MEDICAL SOCIETY.—At Edgware General Hospital, 10.30 a.m., Dr. J. Mowbray: Management of Chronic Renal Failure.

Notice to Authors

When original articles and letters for publication are not submitted exclusively to the *British Medical Journal* this must be stated.

Correspondence on editorial business should be addressed to the Editor, *British Medical Journal*, B.M.A. House, Tavistock Square, London W.C.1. Telephone: 01-387 4499. Telegrams: *Aitiology, London W.C.1.*

Authors wanting reprints of their articles should notify the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs.

Subscriptions

Members' subscriptions should be sent to the Secretary of the British Medical Association, B.M.A. House, London, or to the Scottish Secretary, B.M.A. Scottish Office, Drumsheugh Gardens, Edinburgh.

Doctors who are not members of the B.M.A. can subscribe to the *B.M.J.* The rates for doctors resident in the United Kingdom and abroad are given on the first page of the classified advertisements. These include the rates for the Australian edition and the North American "Air Express," which are available to both members and non-members of the B.M.A.

Classified Advertisements

Doctors Abroad.—Copies of the appointment vacancies advertised in the *B.M.J.* can be sent by air mail on request. The minimum cost is 3s. per week, for which copies of vacancies in up to five sections of the classified advertisements will be sent. The cost of each further section after five is 1s. Orders for specific grades in any section cannot be accepted. Payment should be enclosed with the order.

Details of rates, etc., for classified advertisements appear on the first page of the classified section.

Committee on Medical Science, Education, and Research

Owing to a suggestion by the Film Committee that its title and functions should be broadened to encompass the new department of audio-visual communication, the Committee on Medical Science, Education, and Research briefly discussed the future organization of the B.M.A.'s scientific activities. The question of how the Association could best help postgraduate centres was referred for investigation to a special committee, which would also consider the future of B.M.A. lectures. Professor O. L. Wade and Dr. W. W. Fulton were appointed to convene a working party to examine the usefulness of amphetamine preparations. Draft regulations for a B.M.A. research fellowship of £1,500 a year were approved. The Council is to be asked to press for adequate rehabilitation and long-term treatment facilities for drug addicts who have completed their initial treatment.

The Committee on Medical Science, Education, and Research held its first meeting of the session at B.M.A. House on 19 September. Mr. A. LAWRENCE ABEL was re-elected Chairman and Sir RONALD TUNBRIDGE was re-elected Deputy Chairman.

Size of Committee

The Committee considered a request from the Council that central committees should reduce their size to the minimum compatible with the work of the committee, and also reduce the number of subcommittees where possible.

It was agreed that a Chairman's subcommittee should be formed to consider urgent matters and matters which it was unnecessary for the full Committee to discuss. Mr. R. V. Cooke (President), the Chairman, the Deputy Chairman of the Committee, and Dr. R. Cove-Smith were appointed as the Chairman's Subcommittee.

Recruitment of Members

It was reported that the Organization Committee, in a recent report to the Council, had expressed a hope that each of the major medico-political committees of the Association would consider how best to recruit members.

Dr. W. W. FULTON said that in recruiting meetings held in various medical school areas much emphasis had been laid on the B.M.A.'s scientific work. He thought that sometimes the trade union aspects of the Association tended to get more prominence, and he suggested that every five years or so a brochure might be published describing its scientific activities. It should mention the awards for research available to members. Dr. D. P. STEVENSON, Secretary, supported Dr. Fulton's suggestion.

Film Committee

It was reported that, now the department of audio-visual communications had been established, the Film Committee thought that its title and terms of reference were inappropriate. Neither of them were broad enough to cover all aspects of the audio-visual field. It was considering, therefore, recommending to Council that the Committee should be renamed the "Audio-visual Communications (Film) Committee," and that its terms of reference should be, say, "to be responsible for the Association's activities in the sphere

of audio and visual communications." It was also proposed to strengthen the Committee by inviting members with experience of the subject to serve on it.

Dr. T. QUILLIAM, Chairman of the Film Committee, said that a director of the department of audio-visual communications had been appointed (*B.M.J.*, 13 May, p. 453), and the Film Committee had arranged for a meeting on the technological aspects of medical education and had planned a series of activities.

The CHAIRMAN said that this matter was still in the melting-pot, and he thought it was several months too soon to consider it.

Professor D. E. C. MEKIE said that the Film Committee should not take medical education under its wing. Dr. QUILLIAM replied that it was a matter of technology. The Film Committee's function was to improve the way in which teaching material was conveyed to the students. Dr. FULTON suggested that the title should be reviewed from year to year.

Dr. ARNOLD BROWN thought it would be wise to postpone a decision. The methods of audio-visual communication could change, and might be quite different in two years' time. Mr. R. MYLES GIBSON supported him.

Dr. STEVENSON pointed out that the department of audio-visual communications had to be responsible to somebody. It could not be responsible to the Film Committee, because its commitments covered a wider field, nor to the Committee on Medical Science, Education, and Research, since that Committee was not constituted to supervise the audio-visual field. He suggested that the Committee should agree to "a modest change" in the title of the Film Committee without prejudice to further discussions on the subject.

The Committee accepted this suggestion.

Biological Council

A suggestion was considered that the Association should apply for affiliation to the Biological Council, which was formed in 1945, to enable representatives of societies and associations in the biological sciences to meet periodically to discuss common problems and to draw on each other's experience. It was largely on the initiative of the Biological Council that the Institute of Biology was founded in 1950, and it was represented on committees dealing with scientific documentation and with biological education and the training of technicians, and it also maintained an interest in schemes designed to provide accommodation for scientific societies.

The Committee agreed to recommend to the Council that the Association should apply for affiliation to the Biological Council.

Amphetamine Preparations

The Committee received a report that the Council, on receiving the Committee's recommendations that the possibility of prohibiting the manufacture of amphetamine preparations except in liquid form should be explored, had amended the recommendation to read, "that the position be explored of the usefulness or otherwise of amphetamine preparations." Consideration had been given to the establishment of a working group to carry out this recommendation, and it was noted that the Home Office had asked to receive a copy of the group's report when available.

Dr. FULTON said that the recommendation of the Joint Formulary Committee, on which he served, had been that amphetamine preparations should be withdrawn from the *British National Formulary*. There was some objection to complete withdrawal of the drug, but its use as a stimulant or anti-depressant was condemned. He thought the aim should be to discontinue combinations of amphetamines with other preparations such as sedatives. The Joint Formulary Committee had considered that amphetamine had a use, but only a limited one.

It was agreed to appoint Dr. Fulton and Professor O. L. Wade to set up a working party on which the Psychological Medicine Group Committee and the General Medical Services Committee, among others, would be represented.

Lectures

The Committee agreed that the Sir Charles Hastings Lecture should be further suspended during 1967-8. A report was received that during the 1966-7 session 144 B.M.A. lectures had been arranged for Branches, Divisions, and medical students' societies in the United Kingdom.

The Committee considered a suggestion from the honorary secretary of the North Wales Branch that B.M.A. lectures should be abandoned. His view was that postgraduate centres would rob the B.M.A. of any reason for having scientific lectures, and he thought the B.M.A. lectures should become an integral part of a week-end course at a postgraduate centre.

Dr. STEVENSON said this was an important point. The Association was now offering all its facilities to the postgraduate centres, of which there were some 200. He thought the future of medicine lay in postgraduate centres, and the B.M.A., which had much to offer these centres, must adapt itself accordingly.

Mr. MYLES GIBSON pointed out the contributions that the department of audio-visual communications could make in this field. Dr. STEVENSON thought that the money now spent on B.M.A. lectures could be used to better advantage providing facilities in postgraduate centres. He suggested that the day of the formal lecture was past.

Professor J. H. MIDDLEMISS thought that the B.M.A. should approach postgraduate deans. Professor MEKIE did not think the usefulness of the B.M.A. lectures had passed. More important, however, was the question of the continuing influence of the Association in postgraduate centres. Dr. J. WEDGWOOD said that clinical teachers would welcome help from the B.M.A.

Dr. FULTON said there should be a continuous programme arranged and syllabuses should be approved in advance so that the lectures qualified for postgraduate grants, which would be a great incentive. Social activity was important. The B.M.A. could not compete with the big symposia arranged by drug houses, which were very costly. There was a place for non-scientific B.M.A. lectures, and one held in Glasgow in 1966 on sculpture had been the most successful one in Glasgow for 22 years.

Dr. I. FIELD, Assistant Secretary, said the Committee could, if it wished, make representations to the Council to amend the present constitution of the B.M.A. lectures.

It was agreed to establish a committee to investigate the position and to prepare a report for the next meeting on how the B.M.A. could best help postgraduate centres. The President, Dr. Wedgwood, Professor Mekie, and Dr. Fulton were appointed as the Committee, together with a nominee of the Film Committee.

Computer Courses

It was reported that, after two successful computer courses in London in May and June, arrangements were in hand for a course on computers in medicine in Manchester on 12 October and one in Edinburgh on 26 October. Arrangements were being made to hold a similar course at Rhyl in January 1968.

Dr. FIELD reported that the joint symposium on the application of mathematical and computer methods to problems in medicine was arranged for 6 December, and would be an all-day meeting. This would be a combined effort of the B.M.A. and the Institute of Mathematics. It would be designed for those who already had an interest in this field.

The Committee agreed to ask the Finance Committee for a contribution of up to £100 towards the cost of the symposium.

Budget

The Committee considered the following statement on its estimated expenditure for 1967 and its expected expenditure for 1968:

	1967 £	1968 £
Research scholarships and grants	2,400	2,400
Prize expenses, awards, etc.	550	550
B.M.A. lectures	3,750	3,750
First-aid conference	250	—
B.M.A. Nuffield Library expenses	7,200	8,350

There was criticism of the increase in the library expenditure, though its importance was recognized. Dr. FIELD said most of the increased expenditure would be owing to rises in the cost of periodicals. It was agreed to ask the Library Committee to re-examine expenditure as the year progressed.

Research Fellowship

The Committee considered draft regulations for a B.M.A. Research Fellowship for whole-time research in any subject related to the causation, prevention, or treatment of disease. The Fellowship would be awarded only to

members of the Association. It would be an annual one and to the value of £1,500. It would be renewable for a second and final year if required, subject to a satisfactory progress report. The Association would also be prepared to consider a grant, not exceeding £300 a year, to cover approved expenses of the candidate. It was assumed that the head of the department in which the research fellow worked would be his supervisor.

Lister Centenary

The Committee considered a preliminary report of its steering committee set up to make recommendations on suitable ways for the Association to celebrate in 1967 the Lister Centenary. The report dismissed the idea of a single lecture in favour of a symposium designed to launch an exhibition in B.M.A. House, which would emphasize the links between Lister and the B.M.A. The steering committee recommended a half-day symposium, under the chairmanship of the President of the B.M.A., on the structural design of operating-theatres in relation to the control of infection.

Mr. G. E. MOLONEY, a member of the steering committee, who attended by invitation for this item, said the basic idea was to get together all those interested in operating-theatres to produce something creative as a commemoration. As many workers in related fields as possible should be invited to take part.

Mr. MYLES GIBSON, also a member of the steering committee, said it was understood that the Army would help with a demonstration of mobile theatre units. It would be possible to organize the event in early December.

The Committee decided to recommend to the Council that a symposium on the lines suggested should be held in December, and to ask the steering committee to make the detailed arrangements.

Drug Addiction

The Committee considered a resolution of the Annual Representative Meeting 1967 recommending that there should be adequate provision for rehabilitation and long-term follow-up for patients who have completed treatment for drug addiction. The Government, the resolution stated, should be urged to implement all the other recommendations of the Brain Committee.

The CHAIRMAN said that treatment was almost useless without rehabilitation. Dr. FULTON said everything existed on paper but not in fact, and the Committee must stress that facilities should be provided as soon as possible.

The Committee agreed to recommend to the Council that action should be taken and also that the matter should be taken up at the Parliamentary and Scientific Committee.

Conference on Medical Education

The Committee considered a letter from the Secretary-General of the World Medical Association concerning the organization of

the fourth World Conference on Medical Education (*B.M.J.*, 23 September, pp. 749 and 795). It asked the B.M.A., among other associations, to establish a group of medical education experts to provide the W.M.A. council with guidance, continuing suggestions, and constructive criticism on the programme for the conference.

Dr. STEVENSON said that the conference would be held in Europe probably in 1972. Dr. FULTON said it would be a pity if the British medical scene was totally neglected. Dr. STEVENSON thought it would be possible for the Association to pay the fares of a substantial number of speakers if the conference was held in Europe.

Legislation on Drugs and Medicines

The Committee considered the Government's White Paper on Forthcoming Legislation on the Safety, Quality, and Description of Drugs and Medicines (*B.M.J.*, 16 September, pp. 689 and 734).

Several speakers much regretted the proposed legislation and said they would prefer the existing system to continue. The CHAIRMAN said that the new system would need an army of civil servants to administer it.

Dr. FULTON criticized Clause 15 as too vague, and said the Committee should express its reservation at this stage. He went on to attack Clause 48, which would permit

in certain circumstances sales over the counter and the manufacture of herbal remedies not containing drugs. He said that some herbal remedies could be quite potent. Dr. M. WEATHERALL said that Clause 48 seemed much too loose as it stood. It was perfectly possible to make lethal mixtures. He was also surprised at the retention of the Poisons Boards. He said there should be only one body.

Dr. FULTON said that there was no doubt that the whole set-up of the marketing of drugs needed codification and the White Paper was a commendable attempt.

It was agreed to submit a report to the Council on the White Paper.

B.M.A. Emergency Treatment Service

The Chairman of the Inner London Executive Council of the National Health Service, Mr. G. F. Rowe, denied last week that the council was to blame for the temporary abandonment of the British Medical Association Emergency Treatment Service, which was to have been operated in London by Telephone Answering Services Ltd.

Doctors in the London area were informed by the Emergency Treatment Service (a deputizing service) at the beginning of September that the response from doctors was too small to justify operating the scheme. The Chairman of the Central Advisory Committee of the B.T.S., Dr. I. M. Jones, and the managing director of Telephone Answering Services Ltd., Mr. J. W. Tayler, stated in a letter that there had been "considerable delay" in obtaining official approval for the service, and they considered

that the slow response from the doctors might "in some measure" have arisen from the delay. They said that the deputizing service would begin when enough doctors had enrolled.

Mr. Rowe's statement last week said that the B.M.A. first informed the Inner London Executive Council in December 1966 of the intention to start the deputizing service. A meeting between the organizers and sponsors and the Deputizing Arrangements Committee of the executive council could not be arranged until 19 May. Though the executive council was satisfied that the service sponsored by the B.M.A. would be of a high quality, the council had, in the interests of the doctors who would use the service, to require it first to sort out its own company structure, which was then being changed. The executive council had been "very concerned at the booklet which had been issued

by the British Medical Association to London doctors." This had not given information on, among other important matters, the name of the company with whom the doctors would be contracting, and the contract form was "quite unacceptable." The booklet had since been withdrawn.

Any delay from that stage was due, Mr. Rowe points out, to the need for action by the organizers to meet the executive council's objections. The alteration of the company structure of Telephone Answering Services Ltd. was completed in August, and the appropriate committee of the executive council approved the deputizing service on 22 August. "The scheme," Mr. Rowe's statement concluded, "had legal implications for subscribers which the council had to deal with, and in no circumstances can the blame for any delay be laid at the door of the executive council."

Medical Staffing in the National Health Service in England and Wales

The introductory text printed below and the Table reproduced overleaf have been provided by the Ministry of Health. Similar information relating to Scotland, provided by the Scottish Home and Health Department, is printed at p. 7.

The accompanying Table shows the number of doctors in posts above house-officer grade in National Health Service hospitals and in general practice. Doctors employed by local health authorities and doctors who do not have contracts with hospital authorities or executive councils are not included.

The Table attempts to indicate for each specialty the relation between numbers undertaking specialty training and the number of permanent posts expected to become vacant in the specialty. In tabulating this information it has been necessary to oversimplify the true position and to make some assumptions which may be queried.

Column I gives annual output of the senior registrar grade on a three-year basis, though it is recognized that four years of training at the senior registrar level is often required

unless sufficient experience has been gained at registrar level.

Column J gives estimated figures for annual deaths and retirements of consultants and S.H.M.O.s with allowance from all causes. These figures are estimated actuarially from a knowledge of the age structure of these grades in 1966 and from past experience of actual deaths and retirements in the specialty concerned.

Column K gives the average annual expansion of the consultant grade in the specialty over the past three years. Column L gives the sum of columns J and K. Column M represents an attempt to show in which specialties there seem to be too few or too many doctors undertaking specialty training at senior registrar level in relation to likely consultant vacancies. In most specialties

expansion of the consultant grade over the last year has led to improved prospects for senior registrars in training. This improvement is reflected in an increasing number of asterisks in column M. Growth of the consultant grade has continued through 1967, and it is expected that the 1967 Table, to be prepared as early as possible in 1968, will show further improvement in prospects for senior registrars. The Table is similar to that for 1965 (*Supplement*, 24 December 1966, p. 240). It relates to the position at 30 September 1966. It is constructed from returns provided by hospital boards and executive councils. Collection and checking of these returns takes some time, but the Table this year has been produced three months earlier than last year, and every effort will be made to provide the information earlier in future years.

Medical Staffing in the National Health Service in Scotland

The accompanying Tables show the number of doctors in posts above house-officer grade in National Health Service hospitals and in general practice in Scotland. Doctors employed by local health authorities and doctors who do not have contracts with executive councils are not included.

The Scottish figures are not shown in exactly the same form as are the figures for England and Wales. This mainly arises because of differences in the forward estimating of development of the consultant establishment. There are also some minor deviations in the specialty headings owing to the small numbers involved.

In column H the estimated annual number of consultant posts to be filled in Scotland takes into account losses due to retirement and illness and expansion to the numbers recommended in the Report on Medical Staffing Structure in Scottish Hospitals (Wright Report). It also allows for a small

element of expansion beyond this number to allow for developments in teaching, research, and new advances in medicine which involved no service commitment at the time the Wright Committee was deliberating.

At present the senior registrar establishment in Scotland is estimated broadly on a four-year training basis, but this is only an average figure, and the actual number of years spent in training varies considerably between specialties. The 1967 establishment for senior registrars is 312, while the number in post at 30 September 1966 (column E) was 263. The Tables are based on staff in post on 30 September, and this is a common time for changeover in posts. There is therefore a relatively large number of transitional vacancies.

Adjustments have been made in the establishment to allow for likely developments in certain specialties. Because of these variations and adjustments, column I is not simply column E divided by four but is rather an

estimate of the output which it is hoped to attain within the next few years. The senior registrar establishment is adjusted each year to take account of movement out of and into Scotland and of incidental losses. The excess of column I over column H is accounted for by the present net average movement out of Scotland of 10 senior registrars per year. The aim is to produce a situation in which every senior registrar with the requisite qualifications and experience can expect to obtain a consultant post and at the same time ensure that there is a reasonable number of candidates available for each post. This may not always be possible, since some specialties are less attractive than others and experience difficulty in obtaining suitable candidates. The ratio of the number of registrars born in the U.K. and Republic of Ireland to the number of senior registrars in each specialty will express to some extent the prospects in that specialty.

Private Practice Committee

The Committee deplored the lack of active support given by the Association to its official policy to promote private practice. It also decided to request the Council to implement its undertaking to "do all in its power" to support Independent Medical Services Limited.

The Private Practice Committee held its first meeting of the session on 27 September. Dr. I. M. JONES was unanimously re-elected chairman, and Dr. J. E. MILLER re-elected vice-chairman.

The CHAIRMAN welcomed Dr. J. P. Grier and Dr. P. G. Jones as new members of the Committee, and he paid tribute to the retiring members, Drs. R. Green, R. D. Summers, R. Hale-White, and W. B. Adam.

Charges for Services

The Committee considered the following resolution of Council at the request of the Organization Committee: "That all Association committees be invited to consider the question of charges for services, if any, in their respective fields and to make recommendations."

Dr. J. E. MILLER thought the resolution must mean that if any project initiated by the Private Practice Committee attracted the interest of non-members of the Association consideration should be given to charging those of them who availed themselves of any benefits resulting from the project. Dr. Miller said he felt strongly about non-members benefiting from the services of the Association for which members paid handsomely. He pointed out that non-members had benefited without charge from the B.M.A.'s work in assisting doctors with car parking, particularly in the London area. The idea of making a charge might be extended in that connexion, said Dr. Miller.

Dr. G. R. SMITH suggested that the legal position should be investigated, and the Committee agreed to seek guidance on the matter from the Association's solicitor.

Road Traffic Subcommittee

In presenting the report of the Committee's Road Traffic Subcommittee (formerly the Car Parking Subcommittee), Dr. W. A. H. STEVENSON said that he would welcome closer liaison between the Inner London Local Medical Committee and the Subcommittee on the matter of car parking.

He reported that arrangements had been made for the supply of 2,000 self-adhesive signs bearing the words in fluorescent red: "Doctor—Emergency Duty. Issued by the British Medical Association." It was recommended that the signs should be sold to members of the Association at 2s. each and to non-members at 10s. each, including postage.

The recommendation was adopted.

Referring to the supply of 2,000 self-adhesive plastic car badges with white insert cards, the CHAIRMAN asked the Committee to consider a suggestion by Dr. A. N. Mathias that from the earliest possible date the fee for the provision of the special parking badge for non-members should be at least two guineas. The original recommendation of the Private Practice Committee had been that the badges should be sold to members of the Association for 7s. 6d. each, including postage, and at 10s. each to non-members.

The Council had adopted the recommendation, with the substitution of £1 for 10s.

On the motion of Dr. G. R. SMITH, duly seconded, the Committee agreed to recommend to the Council that the charge for the badge to non-members should be £2, including postage.

Fees

The Committee considered a proposal from the North of England Branch Council that the scale of recommended fees for certificates and reports provided outside the Health Service should be printed on a card which doctors could keep readily available.

The CHAIRMAN reminded the Committee that when it considered the matter in January it had decided to take no action. It had always been the policy of the Association, he said, that a fee charged for any service to a patient was a matter for arrangement between the patient and the doctor.

Dr. MILLER pointed out that the fees concerned were recommended for the guidance of doctors and were not statutorily laid down. Some local medical committees had actually printed a small card setting out recommended fees.

The Committee rejected the Branch Council's proposal.

Notification by Police

The Committee agreed that a letter should be sent to all chief constables requesting that when the police were called after the discovery of a dead person they should notify the person's doctor as soon as practicable.

Alternative Medical Services

The CHAIRMAN drew attention to the following resolution of the A.R.M., 1967: "That this Meeting requests Council to introduce an item-of-service insurance scheme for private practice. Such a scheme of insurance for private practice must include medical care within hospitals and nursing homes and should not be restricted to specialists."

The Chairman, speaking also as Chairman of the Committee of Management of Independent Medical Services Ltd., said that I.M.S. had decided some time ago that at the earliest date it would try to evolve a partial reimbursement scheme. The scheme was now almost complete, and full details would be available for the Committee at its next meeting.

Dr. P. G. JONES said that in his view the Association had failed lamentably in its support of Independent Medical Services. The schemes produced by I.M.S. were practical and workmanlike, but he had yet to see it fully advertised, for instance, in the *British Medical Journal*.

Dr. S. F. LOGAN DAHNE agreed. There had been powerful opposition to I.M.S. and not enough active support, he said.

Dr. M. LANDAU said there had been publicity for I.M.S. The Chairman had addressed B.M.A. Branch and Division meetings up and down the country, but if doctors

did not turn up in any numbers to those meetings what could be done?

The CHAIRMAN said that he had attended many meetings, and, though I.M.S. was officially supported by the Association, it had been rare for another member of the Council to be present. "I am told that many members of Council do not support it," he continued, "but when it was put to the vote in Council only two members voted against it."

Dr. LANDAU suggested that I.M.S. might have come into being at an unfortunate moment for it, in that doctors were now doing better out of the N.H.S. than they had been a few years ago.

Dr. H. FIDLER said that it was up to the Council of the Association to support the I.M.S. scheme.

Sponsored by B.M.A.

Dr. MILLER said that Independent Medical Services had been sponsored by the Association, and on repeated occasions the Council and those in positions of responsibility had paid lip service to their support of it. It had, however, been nothing more than lip service. "The least we are entitled to expect is that the force and the power of the B.M.A. will be behind the operation of I.M.S." Dr. Miller said that he thought this was the opportunity for the Committee—which, by definition, encouraged private practice—to go on record as saying that it was dissatisfied, disappointed, and resentful of the negative attitude of those in a position to assist and encourage I.M.S. If as a result of that negative attitude I.M.S. failed, he said, then the blame could be laid fairly and squarely on those who were responsible for frustrating its efforts at the very beginning.

Dr. P. G. JONES suggested that a letter should be sent to every member of the Association setting out the policy of the Association towards Independent Medical Services. Dr. G. R. SMITH said that the Association was not critical enough of the National Health Service. There was a feeling in the periphery that the B.M.A. had one foot over the Ministry fence. The General Practitioners Association and the Medical Practitioners Union had gained prominence because they had voiced strong criticism. Dr. Smith suggested that I.M.S. ought to look into the N.H.S. doctors' contract, to point out where it was at fault, and to indicate its deficiencies. The profession must feel that I.M.S. could offer members something.

Dr. MILLER, in reply to Dr. Smith, pointed out that the General Medical Services Committee was extremely critical of Ministry policy. On occasions a stronger line might have been taken, he said, but it should not be thought that the G.M.S. Committee was bending over backwards to fall into line with Ministry policy.

Dr. LOGAN DAHNE proposed that the Committee should deplore the lack of active support given to the policy of the Association for the promotion of private practice, and that it should request the Council to implement its past undertaking to do all in its

power to carry out Association policy in support of Independent Medical Services.

The Committee supported this proposal.

Road Accidents

The Committee agreed that renewed representations should be made to the Ministry of Transport for payment of an adequate fee for emergency treatment under the Road Traffic Act, and that steps should be taken to ensure that the fee was paid to the doctor first attending the patient whether it was at the scene of the accident or at the hospital.

Discount Service

As foreshadowed in the Supplementary Annual Report of the Council (*Supplement*,

1 July, p. 13), discount trading facilities are to be provided for doctors by Independent Medical Services Ltd. The Annual Representative Meeting, 1967, gave its approval to this proposal when it accepted the report of the Private Practice Committee (*Supplement*, 22 July, p. 94).

The service will operate as the Facilities Division of Independent Medical Services Ltd., and it will arrange the supply at a discount of a wide range of goods, professional equipment, car purchase, car hire, purchase, and credit facilities. It is stated that further facilities will be added later. The service will be available exclusively to members of the B.M.A., to doctors who have subscribed to the funds of I.M.S., and to medical students belonging to the B.M.S.A. There is no entrance or membership fee.

Information may be obtained from the Manager, Facilities Division, Independent Medical Services Ltd., Tavistock House South, Tavistock Square, London W.C.1.

H.M. Forces

ROYAL NAVY

ROYAL NAVAL RESERVE

Surgeon Lieutenant-Commander C. Fleming has re-entered into the Active List of the permanent R.N.R.

Surgeon Lieutenant M. W. G. Wren to be Surgeon Lieutenant-Commander.

ARMY

Major-General M. H. P. Sayers, O.B.E., Q.H.P., late R.A.M.C., has retired on retired pay.

Brigadier R. A. Smart, C.B.E., late R.A.M.C., to be Major-General.

Colonel H. C. Jeffrey, late R.A.M.C., to be Brigadier.

HOUSEHOLD CAVALRY, ROYAL HORSE GUARDS

Surgeon Captain J. P. A. Page to be Surgeon Major.

ROYAL ARMY MEDICAL CORPS

Majors J. McEwan and T. D. Jones to be Lieutenant-Colonels.

Branch and Division Meetings to be Held

Honorary Secretaries of Branches and Divisions are asked to send notices of meetings to the Editor at least 14 days before they are to be held.

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

BIRKENHEAD AND WIRRAL DIVISION.—At Larch House, Clatterbridge Hospital, Tuesday, 10 October, 8 for 8.30 p.m., Dr. R. Winston Evans: "Recent Advances in Cancer Research."

BRADFORD DIVISION.—At Bradford Royal Infirmary, Wednesday, 11 October, 8.15 p.m., Dr. J. Henry: "The Swan Song of an A.F.D."

BRIGHTON AND MID-SUSSEX DIVISION.—At Sussex Postgraduate Medical Centre, Brighton General Hospital, Tuesday, 10 October, 8.30 p.m., annual general meeting.

BROMLEY DIVISION.—At Elmswood Recreation Hall, Farnborough Hospital, Wednesday, 11 October, 8.15 for 8.30 p.m., Dr. G. F. Vaughan: "Child Psychiatry." Dr. C. H. C. Upjohn will open the discussion.

BUCKINGHAMSHIRE DIVISION.—At Archway Unit, Stoke Mandeville Hospital, Friday, 13 October, 8.15 p.m., annual cheese and wine party. Ladies are invited.●

CAMDEN DIVISION.—At B.M.A. House (Room "D"), London W.C., Tuesday, 10 October, 8 p.m., jointly with City and St. Marylebone Divisions, symposium on "Drug Addiction." Speakers, Dr. A. J. Hawes, Dr. W. Lindsey Neustatter, Dr. D. Stafford-Clark, Mr. H. B. Spears (Home Office). Guests are invited.

CITY OF EDINBURGH DIVISION.—At 7 Drumsheugh Gardens, Wednesday, 11 October, 8.15 p.m., "Young Doctors' Night." Guests are invited.

COVENTRY DIVISION.—(1) At Warwick Road Congregational Church, Sunday, 15 October, 6.30 p.m., annual church service. (2) At Hotel Leofric, Thursday, 12 October annual dinner. Guest of honour, Reverend Lawrence Jackson.

DONCASTER DIVISION.—At Rogerthorpe Manor Country Club, Friday, 13 October, 8 for 8.30 p.m., ladies' night dinner and dance.●

DORSET DIVISION.—At Ballroom, Harrison Hospital, Dorchester, Friday, 13 October, 8 for 8.30 p.m., annual dinner. Guest of honour, Dr. J. Revans.●

EAST YORKSHIRE BRANCH.—At Hull School of Nursing, Hull Royal Infirmary, Anlaby Road, Wednesday, 11 October, 8.30 p.m., Mr. W. W. Slack: "Surgery of Non-neoplastic Conditions of the Colon."

FINCHLEY DIVISION.—At Board Room, Finchley Memorial Hospital, Tuesday, 10 October, 8.30 p.m., Dr. A. M. Ramsay: "The Expanding Field of Infectious Diseases."

GLASGOW DIVISION.—At Livingstone Tower, Strathclyde University, Tuesday, 10 October, 8 for 8.30 p.m., joint meeting with Glasgow and West of Scotland Branch of Pharmaceutical Society of Great Britain, Mr. C. G. Jeffery (Home Office): "The Drugs Problem."

GLOUCESTERSHIRE BRANCH.—At Carlton Hotel, Cheltenham, Thursday, 12 October, 6.30 p.m., presidential address by Dr. K. M. Tomlinson: "A Country Tomb." Followed by dinner.

GREENWICH AND DEPTFORD DIVISION.—At 25 Manor Way, Blackheath, Wednesday, 11 October, 8.30 p.m., wine and cheese party for members and wives.●

HUNTINGDON AND PETERBOROUGH DIVISION.—At Nurses' Home, Peterborough Memorial Hospital, Wednesday, 11 October, 8.30 p.m., B.M.A. lecture by Dr. J. A. Clarke: "Drug Addiction."

KINGSTON-UPON-THAMES DIVISION.—At Outpatients Department, Kingston Hospital, Tuesday, 10 October, 7.30 p.m., clinical meeting.

LEEDS DIVISION.—At Parkway Hotel, Thursday, 12 October, 7.45 for 8.15 p.m., annual dinner and dance.

MEDWAY AND GRAVESEND DIVISION.—At Boardroom, St. Bartholomew's Hospital, Rochester, Sunday, 8 October, 10.30 a.m., annual general meeting.

MERSEYSIDE BRANCH.—Wednesday, 11 October, annual general meeting.

NUNEATON DIVISION.—At Chase Hotel, Tuesday, 10 October, 8 for 8.30 p.m., annual valedictory dinner and ladies' night, Professor A. P. Griffiths: "The Incipient Drug Problem."●

PLYMOUTH DIVISION.—Wednesday, 11 October, 6 p.m., visit to new District General Hospital Site at Derriford.●

RENFREWSHIRE DIVISION.—At Kilmacolm Hydro Hotel, Friday, 13 October, 7.15 for 8.15 p.m., annual dinner and dance.●

SOUTH-EAST ESSEX DIVISION.—Tuesday, 10 October, visit to cosmetics factory of Messrs. Yardley. Meet at main gates, 2.10 p.m. Ladies are invited.●

SOUTH SHIELDS DIVISION.—At Nurses Lecture Unit, Ingham Infirmary, South Shields, Wednesday, 11 October, 8.30 p.m., B.M.A. lecture by Dr. J. Fry: "Medical Care Behind the Iron and Golden Curtains."

SUTTON DIVISION.—At Worcester Hotel, Worcester Park, Wednesday, 11 October, 7.30 for 8 p.m., annual dinner and dance.●

WORCESTER AND BROMSGROVE DIVISION.—At Mitre Oak Hotel, Crossway Green, near Hartlebury, Thursday, 12 October, 8.30 p.m., wine tasting and buffet supper.●

Scottish Committee for Hospital Medical Services

The Scottish Committee for Hospital Medical Services (formerly the Central Consultants and Specialists Committee (Scotland)) held its first meeting on 25 September at B.M.A. House in Edinburgh. Mr. N. G. C. HENDRY and Dr. A. ALLISON were appointed Chairman and Deputy Chairman respectively.

Dr. J. G. M. HAMILTON was reappointed Treasurer of the Central Consultants and Specialists Committee (Scotland) Fund, and it was agreed that consideration should be given to renaming this fund so that it would correspond with the new name of the Committee.

Outpatient Prescriptions

Further consideration was given to the question of prescribing for hospital outpatients, and to the use for this purpose of a form (Form R.B.P.) intended for prescribing drugs unobtainable in the hospital pharmacy for outpatients not being referred to their general practitioners. Two regions thought that an attempt was being made to reduce the use of this form, and the Committee had regarded this as a possible interference with a doctor's clinical freedom.

The Committee agreed to make the following three comments on the matter through the Joint Consultants Committee (Scotland) to the Scottish Home and Health Department: (1) that this valuable facility should not be withdrawn; (2) that the profession could accept only with reservations the fact that the charge for the drugs so prescribed had to go on the hospital budget; and (3) that if there appeared to be any interference with the freedom of hospital doctors to prescribe the matter would be brought up with the Department again.

Dr. A. J. SANGSTER said he believed that the cost of prescriptions on Form R.B.P. was being charged to boards of management, and as a result they had not enough money to purchase essential equipment.

It was agreed to ask secretaries of regional committees for hospital medical services to seek definite information on this point.

The Committee received a report that a Scottish hospital memorandum was being prepared on the recognition of overseas and of general-practitioner service in placing newly appointed hospital doctors on an appropriate salary scale. It was also reported that there was no further information about proleptic appointments.

Negotiating Machinery

The Committee considered a paper from the chairman's subcommittee on the new negotiating machinery for hospital doctors in the United Kingdom. The subcommittee suggested that, with the agreement of the Scottish Home and Health Department and of the Joint Consultants Committee (Scotland), matters which in England and Wales came within the remit of the negotiating subcommittee of the Central Committee for Hospital Medical Services should be referred directly to the Department by the Scottish Committee for Hospital Medical Services. The matter could be reconsidered at the end of a year, when it would be possible to assess the working of the negotiating subcommittee in London.

The CHAIRMAN questioned whether it was possible at present to identify enough items relating particularly to Scotland and requiring special reference to Scotland for discussion and decision which at the same time were matters other than those which were the concern of the Royal Colleges. He understood that the Scottish Home and Health Department would meet whatever arrangements the profession chose to make.

Dr. HAMILTON, Chairman of the Joint Consultants Committee (Scotland), pointed out that other constituent members of his Committee would have to be consulted before any changes were made. He suggested that it would be wise to wait to see how matters progressed in England under the Joint Consultants Committee (U.K.) with its new terms of reference, and with the negotiating subcommittee of the Central Committee for Hospital Medical Services.

The Committee agreed with Dr. Hamilton, and decided to reconsider the matter again in a year's time.

The Committee was informed that the Scottish Panel of the "Group of Nine" (the committee appointed in December 1966 by the Joint Consultants Committee (U.K.) to conduct negotiations with the Ministry of Health on the memorandum "Current Problems of Hospital Medical Staff" (*Supplement*, 13 May, p. 93)) had agreed on the principle of an "acting-up" allowance in circumstances such as those which had occurred in Aberdeen, where senior registrars were seconded from Aberdeen to undertake consultant work in Orkney and Shetland in the absence of consultants. The amount of money to be paid in such cases would be a matter for decision by the Review Body.

It was also reported that, after discussions with the Home and Health Department, the Joint Consultants Committee (Scotland) now hoped that arrangements could be made for a special responsibility payment to be paid to general practitioners who undertook unsupervised specialist work in remote hospitals. The General Medical Services Committee (Scotland) proposed to put its views on this matter to the Department in support of the action already taken by the Joint Consultants Committee (Scotland).

Staffing of Departments

Dr. A. ALLISON reported that a meeting had taken place in Glasgow with the Western Regional Hospital Board to discuss the problems that were being encountered in the establishment of and making appointments to the chest service in the region.

The regional board had not disclosed its plans for manning the chest service, but it was already advertising posts for physicians with an interest in chest diseases. Some senior S.H.M.O.s who had been engaged in the work for years thought that the practice of advertising the posts seriously interfered with their chances of being appointed. The Western Regional Committee for Hospital Medical Services had asked the Board that the S.H.M.O.s with special experience should have that experience taken into account in making the appointments.

Dr. W. F. TYRRELL expressed the concern of S.H.M.O.s in this matter. The Committee agreed, however, to wait to see how the appointments that were now being advertised were filled.

The Committee was informed that a paper emphasizing the deficiencies in the staffing of radiological departments in district hospitals had been presented to the Home and Health Department,

which had referred it to the Advisory Committee on Consultant Establishments, and had also agreed to discuss it with senior administrative medical officers. Dr. P. AITKEN welcomed this information and hoped that the question of staffing in diagnostic radiology would continue to be kept under review.

Anaesthetic Services

The CHAIRMAN congratulated Professor A. C. Forrester, Chairman of the Anaesthetic Services Subcommittee, on his appointment to the Chair in Anaesthetics at Glasgow University.

Professor FORRESTER said that his subcommittee had decided that it would be necessary to reconsider its memorandum on senior registrars in anaesthesia in Scotland in view of the recent changes in the consultant establishment in the specialty. In the past year 22 new anaesthetic consultant posts had been filled; 12 of them had been recommended in the Wright Report and 10 more posts had been added.

The subcommittee had welcomed the Report on Dental Anaesthesia by the joint subcommittee of the Standing Medical and Dental Advisory Committee of the Central Health Services Council. Anaesthetists looked forward to the time when dental anaesthetics would be given by specialist anaesthetists, said Professor Forrester. He agreed that the training of doctors in dental anaesthesia could be improved. A start had been made in Glasgow, where registrars now worked in dental departments, and it was hoped that this instruction would be extended to other doctors, in due course.

A further point made by Professor Forrester was that there had been no reference to training and education in anaesthetics in the report of the Working Party on Postgraduate Medical Education. He said that anaesthetics was now one of the largest specialties, and this lack of reference to training in anaesthetics had been a bad omission in an otherwise valuable document.

Medical Assistant Posts

The Committee thought that from reports from regions it appeared that the system of consultation with the profession before the institution of medical assistant posts was reasonably satisfactory.

In answer to a question, Dr. ALLISON said that in the Western Region local views were obtained when the regional committee for hospital medical services received a request for an opinion from the regional hospital board. Dr. SANGSTER asked whether local opinion about the proposed new posts had been conveyed to the advisory committee on consultant establishments. The CHAIRMAN said he thought this always happened, and that further steps were being taken to ensure that the advisory committee had the fullest information. Replying to Dr. G. C. TIMBURY, the CHAIRMAN said that information was being collected by the advisory committee about the filling of medical assistant posts throughout Scotland.

Terms of Service

The Committee next discussed medical examinations of prospective hospital staff, which were usually carried out by hospital

junior doctors. It was queried whether this work was included in the doctors' contract, and what was the precise interpretation of the terms of service in the contract.

Dr. S. J. HADFIELD, Scottish Secretary, informed the Committee that the imposition of this extra work was causing growing concern among hospital junior staff. It had been reported to the Hospital Junior Staffs Group Council (Scotland) recently that the work seemed to be continually increasing. It had also been said that the results of the examinations were not always taken into account by those who engaged the staff.

Professor E. M. MCGIRR referred to the possible introduction in the near future of a hospital occupational health service, and he thought this might help to solve the problem. Dr. HAMILTON agreed that this work represented a continual and unreasonable load over and above the ordinary clinical work of the junior staff.

The Committee agreed to seek evidence from the hospital junior staff regional groups on this matter.

It was reported to the Committee that the Scottish hospital memoranda on study leave, sick leave allowances, removal expenses, and minimum time off duty for junior and intermediate grades of staff had been issued by the Home and Health Department after consultation with the Joint Consultants Committee (Scotland).

Referring to the circular relating to minimum time off duty, Dr. SANGSTER pointed out that even if there were more housemen available there was no extra money for them, nor was there any extra money for the additional accommodation which would be required to house them.

The CHAIRMAN said that in existing circumstances it seemed there was no question of employing extra staff. It was more likely that the services to the public would have to be curtailed if it was not possible to reorganize them within the present budget and with the present staff.

Research and Intelligence Unit

Dr. M. A. HEASMAN, of the research and intelligence unit of the Scottish Home and Health Department, attended the Committee by invitation and spoke on the unit's work. It was set up two years ago with four main functions: (1) to collect information on the working of the Scottish health services; (2) to circulate this information; (3) to engage in research into the working of the health services; and (4) to stimulate others to undertake research. Since that time a fifth function had been added in that the unit had become responsible for the development of computer policy.

Dr. Heasman said that the main points on which data were obtained were on inpatient and outpatient statistics, matters relating to hospital waiting-lists, and information on the discharge of patients from hospital. He said that the material available was not used outside the Health Department as much as it should be. Most of it could be obtained by clinicians for the asking. In difficult cases a clinician could visit the unit and extract the information he wanted.

Dr. Heasman mentioned the Scottish Health Service statistics which were published annually. He said that his unit proposed in future to send to hospitals a summary of

the data on their work. Such data tended to be an indigestible mass, but it was hoped that the data for 1967 would be produced in a more usable form, and would give individual consultants some information on their work and the work of their specialty. The sort of information that would be available would be the age distribution of patients, the length of stay in hospital, and when admitted and when discharged. National averages would also be provided.

Another activity of the unit was the financing of research. Dr. Heasman regretted that so far there had been few applications for financial help from non-university clinicians.

In reply to a question by Dr. P. AITKEN about the statistics on services such as radiology, Dr. HEASMAN said the unit's work did not include this yet, because it was dealing only with clinical data. Dr. A. A. BROWN asked for more information about the distribution of statistical reports on the work of consultants, and Dr. HEASMAN said that in addition to the copy sent to the consultant a confidential copy would be sent to the senior administrative medical officer. What the unit was providing was patient-care evaluation for discussion within the profession.

The CHAIRMAN thanked Dr. Heasman for attending the meeting, and for his helpful exposition of the work of his department.

Increased Junior Representation

Representatives to other committees and the members of subcommittees were appointed, and a recommendation of the chairman's subcommittee that the representation of hospital junior staff on the Scottish Committee for Hospital Medical Services should be increased from two to three was adopted.

Type D General Practice Allowances

The Ministry of Health has introduced a new scheme of special allowances known as "Type D" initial practice allowances (*Supplement*, 23 September, p. 136). The details are set out in a circular (H.C.N. 631) to general practitioners. Special rates of initial practice allowance will be offered to doctors with the necessary qualities and experience who are willing to enter practice in new towns and redevelopment areas concurrently with the arrival of the new residents. The allowance will ensure that the doctors' earnings will remain at the same level as in their previous post, subject to a net maximum of £4,000 a year.

The Type D allowance will continue for a maximum of three years or until the doctor takes a partner, whichever is the sooner. If a partner is appointed a "Type C" initial practice allowance (designed for doctors who join in a partnership) will ordinarily be available, provided the area is a designated one. Doctors appointed to practices which qualify for the Type D allowance will normally be expected to have had about ten years' experience, including two years in hospital appointments, five years in a busy general practice, and experience in obstetrics.

Hospital Junior Staffs Group Council (Scotland)

The first meeting of the session of the Hospital Junior Staffs Group Council (Scotland) was held in Edinburgh on 19 September. Dr. W. P. U. KENNEDY was appointed Chairman, and Dr. G. M. McANDREW Deputy Chairman.

The CHAIRMAN began by making a special appeal for unity among hospital junior staff, and he asked members of the Group Council to encourage their colleagues to support the leadership of the Hospital Junior Staffs Group in London.

Senior Registrars

The Group Council was informed that, with the agreement of the Joint Consultants Committee (Scotland), the question of an "acting-up" allowance for senior registrars required to undertake consultant duties in Orkney and Shetland had been discussed with the Home and Health Department and referred to the Scottish Panel of the "Group of Nine." The Scottish Panel had agreed on the principle of additional payments for these duties, but it was reported that the amount of the payment was a matter for decision by the Review Body.

Dr. R. N. M. MACSWEEN asked that the existing arrangements for the appointment of honorary senior registrars should be changed. Dr. B. GRODEN said that registrars in the National Health Service thought that lecturers who were made honorary senior registrars blocked the establishments, and that there should be more control over the number of these appointments.

The Group Council agreed that it would like to see the document on senior registrar and consultant establishments, which was being prepared by the Subcommittee on Senior Registrars and Consultant Establishments, before it was presented to the Scottish Committee for Hospital Medical Services.

Disciplinary Procedures

The Group Council received a report that no further progress had been made on the question of disciplinary procedures which were under revision in the General Whitley

Council. The matter was held up until a report was available from the Ministry of Labour's Advisory Committee on Disciplinary Procedures and Appeals. Members of the Group Council thought that it was not enough that doctors should be included in any general machinery which was decided upon. Hospital doctors had to adhere to an ethical code and were subject to special discipline, and it was essential, especially since it was thought that distinctions were difficult to make between personal misconduct and professional misconduct, that there should be one disciplinary procedure for doctors to deal with all cases of misconduct.

Dining Accommodation

The Group Council then discussed the question of dining accommodation. Members stated that there was no consultation with hospital junior staff when changes were to be made in the arrangements for residents, and it was believed that often there was no consultation with the senior staff either.

The Group Council thought that regional group committees should agitate for consultation in this matter, and it was resolved to request the Scottish Committee for Hospital Medical Services to ask the Joint Consultants Committee (Scotland) to express the dissatisfaction of hospital junior doctors in this matter to the Scottish Home and Health Department, and to stress the need for consultation with the junior staff when any changes were made in existing hospitals and when any plans were being formulated for new hospitals.

Scottish Hospital Memoranda

A report was received of the progress achieved by the Group of Nine and by the Scottish Panel in the negotiations between the Health Departments and N.H.S. hospital doctors and dentists, as set out in the first and second joint reports on the negotiations (*Supplement*, 27 May, p. 135, and 19 August, p. 119).

Reference was made to the Scottish hospital memoranda which had been issued on sick-

leave allowances, professional and study leave, off-duty time, removal expenses, and the provision of telephones for hospital medical staff.

Some speakers said they realized that there would be difficulties in many places in fulfilling the requirements of the circular dealing with minimum time off duty. Dr. MACSWEEN said that implementation of the circular on study leave was bound to be held up by lack of funds, because no extra money was being provided to pay extra staff, even if they existed.

It was agreed to ask the Scottish Home and Health Department what money was available for implementing the proposals in the hospital memorandum on minimum off-duty time.

It was reported that a hospital memorandum was being prepared on the question of taking into account overseas service by a candidate for a hospital post.

Several members of the Group Council expressed concern about the burden placed on hospital junior staff when they had to examine hospital employees and prospective employees for fitness for duty. The considerable turnover of hospital staff meant increasing work for hospital junior doctors, particularly registrars, who found it difficult to carry out this commitment in addition to their clinical work.

Committee Representation

The Chairman and the Deputy Chairman were appointed to represent the Group Council on the Scottish Committee for Hospital Medical Services, and Dr. Groden was nominated as the third representative, if, as was expected, the Scottish Committee for Hospital Medical Services decided that in future the hospital junior staff representation on that committee should number three representatives.

Dr. McAndrew and Dr. Groden were appointed to the Executive Committee of the Hospital Junior Staffs Group Council (U.K.), and Dr. Kennedy and Dr. A. Auld were appointed to serve on the Scottish Council of the Association.

Occupational Health Committee

The Occupational Health Committee held its first meeting of the session on 4 October. Dr. R. E. W. FISHER was re-elected to the chair.

The Committee considered the position of its Remuneration Subcommittee and of its Negotiating Panel.

The CHAIRMAN pointed out that in the past the subcommittee had advised the Committee on levels of remuneration in general, while the panel had acted as a body from which negotiators could be drawn.

It was proposed that there should be only one subcommittee, which would combine the functions of the remuneration subcommittee and the negotiating panel.

Dr. R. L. LUFFINGHAM said that the functions of the subcommittee and of the panel had been different. The subcommittee had been concerned with setting standards of remuneration, whereas the panel had had to negotiate on a more practical level.

The Committee agreed to the proposal that there should be one subcommittee combining the functions of the Remuneration Subcommittee and the Negotiating Panel.

Charges for Services

Dr. I. T. FIELD, Assistant Secretary, said that all committees had been requested by

the Organization Committee to consider making a charge for services given to non-members.

Mr. J. C. McMASTER thought that advice given to non-members in response to their requests should be charged for.

The CHAIRMAN said that in giving advice about, say, remuneration the B.M.A. was not only providing a service for the doctor or the employer but also a service for the profession, because it was in the interests of the profession that a doctor working in industry should be properly paid, and that the service should be properly run. The Chairman thought it would be difficult to separate the two functions, because one of the B.M.A.'s

responsibilities was to ensure that the health services were properly administered. He deprecated the idea of the Secretariat acting as a consultant body that charged fees.

Mr. McMASTER said that there was a strong feeling within the B.M.A. that services to non-members should be reduced. The Association needed to increase its membership, but if doctors could get its services free, they would not easily be persuaded to become members. The B.M.A. was financed from members' subscriptions. He agreed that the Secretariat should not refuse to give advice, but if this was required by non-members then they should be prepared to pay a small fee towards the cost.

Dr. FIELD said that it might be possible to charge non-members for copies of the booklet *The Doctor in Industry*, which contained the B.M.A.'s recommendations on the terms and conditions of service of industrial medical officers. But the booklet had always been sent to employers-free of charge, on the ground that the Association was providing a service to the whole of industrial medicine. Dr. Field thought that it would be difficult for the B.M.A. to start charging employers for providing them with information on its recommendations on different matters.

Dr. F. H. TYRER said that when a lay body or lay person sought advice no fee should be charged, but doctors who were non-members of the Association should be charged.

The matter was referred to the Committee's Planning Subcommittee for consideration.

Conference of Advisory Councils

The Committee received a report that the conference of Advisory Councils on Occupational Health in 1968 would be on 6 March. The chairman of the conference would be Mr. W. T. Parsons, of Brighton, and the subject for discussion would be "The Scope

and Functions of an Occupational Health Service."

Dr. J. A. SMILEY wondered if these conferences served any real purpose. Dr. TYRER thought they did. But it was unfortunate, he said, that there were still only a handful of advisory councils in the country. He would like to see three times as many. He agreed that the time might come when the question would have to be asked whether the value of the conference was worth what it cost the Association to hold it.

Dr. FIELD said the real question was whether the advisory councils were of any use. He believed that the conference was the one thing which made the councils feel it was worth while continuing. Without this many would fold up.

Dr. A. REEVES said that in the West Riding of Yorkshire the conference was an important matter. If expense was the difficulty he believed that advisory councils would be prepared to share the cost rather than lose the annual conference.

The Committee agreed to discuss the matter again at its next meeting.

Vibration Syndrome

The CHAIRMAN presented the report of a subcommittee which had been considering the vibration syndrome. He said that there was now probably good reason for the vibration syndrome to be proscribed under the National Insurance (Industrial Injuries) Act of 1965.

The subcommittee recommended that the Ministry of Social Security should be informed of this opinion and that a short memorandum supporting this view should be submitted at the same time to the Ministry. The memorandum should include the following points:

(1) There was increasing evidence that the use of vibrating tools was likely to produce minor but uncomfortable disability due to

Raynaud's phenomenon and, less commonly, to affections of the bones, joints, muscles, and nerves of the hand, arm, and shoulder.

(2) The commonness of the condition had not been appreciated because many who suffered from it were able to continue working and accepted the discomfort as an inevitable concomitant of their work.

(3) Not enough was known about the incidence of the condition nor of its varying degrees of severity. It was understood that a research project had started, and it was to be hoped that the research would provide definitive answers to these questions.

(4) The existence of the condition was now so well attested and its specificity to a particular cause was so clear that there seemed to be little purpose in further delaying proscription.

Dr. TYRER asked whether there were clear diagnostic criteria, and the CHAIRMAN replied that, in the view of the experts who had been consulted, there were.

Dr. SMILEY said that two other committees had examined the vibration syndrome, and had decided there was no accepted specificity to a particular cause. Raynaud's phenomenon occurred quite frequently without any contact with vibrating tools.

Dr. TYRER said that to get a disease proscribed it was not essential that a specific cause for it should have to be proved. If persons suffering from this syndrome were granted benefits under the Industrial Injuries Act it would not cost much, because the numbers were so few.

The Subcommittee's report was approved, and it was decided to recommend to the Council that it should write on the lines of the report to the Industrial Injuries Advisory Council.

It was agreed to nominate a deputation to attend the Industrial Injuries Advisory Council to discuss the matter, should that body wish it.

Planning Unit's Progress

The Association's Planning Unit (*Supplement*, 2 September, p. 126), under its director, Professor Henry Miller, continues its work of defining, investigating, and reporting upon specific problems in the National Health Service through a number of working parties of experts.

Mr. Duncan Guthrie, Director of the National Fund for Research into Crippling Diseases, is chairman of the working party on mechanical aids for the disabled. Its remit covers an assessment of the nature and value of available appliances, mechanical aids, and architectural adaptations and their cost; an examination of arrangements whereby these can be provided from public funds; and a review of existing research facilities and proposals for their further development. The medical members of the working party are Dr. J. Agate, Mr. George Bonney, Dr. D. A. Brewerton, Mr. J. Chalmers, Dr. F. Cooksey, Dr. P. J. R. Nichols, Dr. J. J. Walsh, Wing Commander C. B. Wynn Parry, and Dr. G. Yates, together with Mr. A. K. Godden, Department of Engineering Science, University of Oxford, and Mr. A. Kennaway, consulting engineer, London. Dr. Catherine

Dennis is the Ministry of Health's observer.

Under the chairmanship of Dr. E. J. Moran Campbell, of the Royal Postgraduate Medical School, a working party has been established on intensive care units. One group of the working party is investigating and collecting information, and another group will make a critical review of the information. Members of the investigating group are: Drs. E. J. M. Campbell, D. Benazon, E. Sherwood Jones, G. T. Spencer, G. Ford (Ministry of Health), and Miss C. Willman, sister of an intensive-care ward. The membership of the review group is Mr. A. G. Cox, Dr. D. N. S. Kerr, Professor L. P. Le Quesne, Mr. Walpole S. Lewin, and Dr. B. L. Pentecost.

Primary Care

It is probable that a working party will be set up shortly to study the provision of primary medical care. A study group is advising the unit on the best method of investigating the future of primary medical care. Its membership includes Drs. D. Irvine,

G. Curtis Jenkins, R. Logan, G. Marsh, and I. R. McWhinney. The chairman is Mrs. Margot Jefferys, Director of the Social Research Unit, Bedford College, University of London.

The unit has sought advice from the Medical Research Council's computer centre on the possibility of initiating an investigation into computer science in relation to medicine. It will be decided shortly how the unit can best contribute in this field.

Each B.M.A. Branch and Division has been invited to nominate a "forward-looking young doctor" to act as an "unofficial liaison officer" with the Planning Unit. So far over 50 liaison officers have been nominated.

The members of the main Planning Unit are Professor Henry Miller (Director), Newcastle; Dr. John Bennett, Liverpool; Dr. Charles Fletcher, London; Dr. W. G. Harding, London; Miss Josephine Barnes, London; Mrs. Mary Adams (representing lay consumers); Dr. Donald Irvine, Ashington and Northumberland; Mr. Walpole S. Lewin, Cambridge; and Professor O. McGregor, Department of Social Studies, London University.

Full-time Medical Teachers and Research Workers

At its first meeting of the session the Full-time Medical Teachers and Research Workers Committee re-elected Dr. K. S. ZINNEMANN as its chairman and Dr. M. M. BULL as deputy chairman.

The CHAIRMAN welcomed Dr. E. C. Fox (Birmingham), Mr. H. Gordon (London), Dr. J. H. Walker (Newcastle), and Dr. R. S. Kirk (Manchester), deputizing for Dr. H. Fox, as new members of the Committee, and Dr. G. M. Williamson (Pfizer Ltd.), who was co-opted to represent research workers outside the Medical Research Council.

Representative Committees

Reporting on a meeting of the Central Committee for Hospital Medical Services, Professor IAN RANNIE referred to the constitution of the Joint Consultants Committee. In September of last year the Central Consultants and Specialists Committee, as it was then called, had decided to assume the function of negotiating with the Minister on remuneration. The Joint Consultants Committee agreed to reconstitute itself and that negotiations on pay should be left to the C.C. and S. Committee. The C.C. and S. Committee then changed its name to that of Central Committee for Hospital Medical Services so that it could be seen to be representative of all hospital medical staff.

The composition of the Joint Consultants Committee had remained very much the same, but its function now was to deal with matters other than those of terms and conditions of service.

The College of Pathologists and the Royal Medico-Psychological Association had asked to be included in the new Joint Consultants Committee, but the Joint Committee had not yet agreed, nor had it agreed to a suggestion that the Full-time Medical Teachers and Research Workers Committee should be represented on it.

Another point of interest to the Committee was that the ballot on distinction awards had not yet been completed. It had been extended in time so that clinical university teachers with honorary consultant posts could take part in it.

Remuneration of Clinical Teachers

The CHAIRMAN reported that the Government had paid the increase in remuneration due to clinical teachers as from 1 October 1966 in one lump sum on 1 July 1967 instead of phasing the payment as the Government had intended.

The Chairman said that much help in this matter had been received from the Chairman of Council, who had attended every meeting at the Ministry.

The Chairman drew attention to a resolution of the A.R.M. 1967 requesting the Council to continue to press for the inclusion of medical teachers in the remit of the Kindersley Review Body. He said that the Minister of State for Education and Science in August last year had stated that he was thinking of

making the salaries of university teachers (including medical teachers) a standing reference to the Prices and Incomes Board, and he urged those concerned to give him their consent before Christmas last year. Dr. Zinnemann reported that the B.M.A.'s views had been given to the Minister before Christmas, but nothing had happened as yet. He believed that a reference to the Prices and Incomes Board was imminent.

Appointments for Dental Surgeons

The CHAIRMAN said that in July the Chief Dental Officer, Ministry of Health, had issued to the dental schools a paper headed "Appointments in the Hospital Service for Dental Surgeons." At the back of the paper was a diagram which equated senior lecturers and readers in the universities with senior registrars in the hospital service. That had caused the Committee much concern, and it had been pointed out to the Chief Dental Officer that senior lecturers and readers were equivalent to consultants in the hospital service, and that the B.M.A. took strong exception to the diagram.

Professor RANNIE proposed, and the Committee agreed, that the Council should be asked to press for the withdrawal of the diagram.

Grants to Students

Commenting on a report of a working party on grants and welfare presented to the annual general meeting of the British Medical Students Association 1967, Sir RONALD TUNBRIDGE said that students who had no private means and no parents should have enough to live on.

It cost a student who was modest in his demands £600 a year to maintain himself in London. That should be the basic grant. Adjustments might have to be made in cases where students were required to take up residence in hospital for a time and still retain their lodgings. If clinical students were considered as postgraduate students, as many of them in fact were, it would be a great help.

The Committee expressed general agreement with the comments made by Sir Ronald Tunbridge.

Hospitality

A German doctor's daughter living in Munich would like to stay with a British medical family for six weeks from 1 March to 15 April 1968. In exchange the family would be pleased to receive a British girl of similar age for six weeks in June or July.

Would anyone who is interested please get in touch with Dr. R. A. Pallister, Medical Director, International Medical Advisory Bureau, B.M.A. House, Tavistock Square, London W.C.1.

"Mediflash"

From 16 October Mediflash, a portable, flashing green light which can be fixed to the roofs of doctors' cars when travelling to emergencies, will be available to doctors through the British Medical Association (*Supplement*, 8 July, p. 23).

The light can be obtained only by doctors who sign an agreement with the B.M.A. to abide by the following conditions:

- (1) The light remains the property of the Association, and it must be returned to the Association if for any reason the member ceases to be engaged in active practice.
- (2) The light is to be used by registered medical practitioners only while travelling to medical emergencies.
- (3) The use of the light confers no special privileges, and the law, including general traffic regulations and speed limits, must be complied with.
- (4) The light must not be sold or transferred to any other person.
- (5) The Association must be informed immediately if the light is lost or stolen.
- (6) The Association may demand the return of the light if the Association is satisfied it has been improperly used.

No Special Privileges

In a letter to honorary secretaries of B.M.A. Branches and Divisions the Secretary of the Association states that it is essential that doctors should abide rigidly by the conditions, and that the "success of the project depends very much on the co-operation of the profession." Honorary secretaries have been asked to seek the co-operation of the police locally in introducing the lamp. In a letter to chief constables the Secretary emphasizes that the lamp is intended as an identification symbol for a doctor who is seeking the co-operation of the police and other road users to enable him to get through congested traffic as quickly as possible. The B.M.A. understood that it would not confer any special privileges in relation to general traffic regulations and speed limits.

The light will cost £6 6s. for members of the B.M.A. and £7 10s. for non-members.

Central Ethical Committee

At its first meeting of the session on 5 October the Central Ethical Committee appointed Dr. WALTER WOOLLEY to be its chairman. Dr. S. Noy Scott did not seek re-election.

Dr. Noy Scott had been chairman of the Central Ethical Committee since 1957, when he succeeded Dr. Robert Forbes, and before that he had been its deputy chairman since 1952. Tribute was paid by the Committee to his services, and Dr. WOOLLEY welcomed the fact that Dr. Noy Scott would continue to be a member of the Committee.

Dr. Woolley has been a member of the Central Ethical Committee for 18 years, and has been its deputy chairman since 1962.

Association Notices

Diary of Central Meetings

OCTOBER

- 17 Tues. Tuberculosis and Diseases of the Chest Group Committee, 2 p.m.
19 Thurs. Joint Consultants Committee (Scotland) (at 7 Drum-
heugh Gardens, Edinburgh), 10.15 a.m., followed by
meeting with Scottish Home and Health Department at
St. Andrew's House, 2.30 p.m.
19 Thurs. Finance Committee, 2 p.m.
20 Fri. Central Committee for Hospital Medical Services, 10.30
a.m.
21 Sat. Central Committee for Hospital Medical Services, 10 a.m.
24 Tues. Joint Consultants Committee (at Royal College of Physi-
cians and Surgeons of Glasgow, 242 St. Vincent Street,
Glasgow), 10 a.m.
25 Wed. Council, 10 a.m.
26 Thurs. G.M.S. Committee, 10.30 a.m.
26 Thurs. S.H.M.O. Group Council, 2 p.m.

NOVEMBER

- 1 Wed. Annual Meetings Committee, 12 noon.
1 Wed. Liaison Committee with the Royal College of General
Practitioners (at Royal College of General Practitioners,
14 Princes Gate, London S.W.7), 4.30 p.m.
2 Thurs. G.M.S. Planning Working Group on Medical Care in
Rural Areas, 2 p.m.

15 Wed. Alcohol and Road Accidents Committee, 2 p.m.
23 Thurs. Compensation and Superannuation Committee, 2 p.m.
23 Thurs. Dermatologists Group Committee, 2.30 p.m.

DECEMBER

- 13 Wed. Journal Committee, 2 p.m.

Branch and Division Meetings to be Held

Members proposing to attend meetings marked * are asked to notify in advance the honorary secretary concerned.

ALDERSHOT AND FARNHAM DIVISION.—At Physiotherapy Department, Farnham Hospital, Wednesday, 18 October, 8.15 p.m., clinical evening.
BARNESLEY DIVISION.—At Queen's Hotel, Monday, 16 October, 9.15 p.m., annual general meeting.

BRISTOL DIVISION.—At Large Lecture Theatre, Medical School, Wednesday, 18 October, 8.30 p.m., annual general meeting.

DUDLEY DIVISION.—At Wordsley Hospital, Tuesday, 17 October, 7 for 7.15 p.m., Professor R. Milnes Walker: "Some Aspects of Cancer."

DUNBARTONSHIRE DIVISION.—At Queen's Hotel, Helensburgh, Friday, 20 October, annual dinner and dance.

ENFIELD AND POTTERS BAR DIVISION.—At Chase Farm Hospital Academic Centre, Friday, 20 October, 8.30 p.m., Dr. E. W. Emery: "Carcinoma of the Breast—a survey of 20 years' treatment at University College Hospital."

FERMANAGH DIVISION.—At Manor House Hotel, Killadeas, Enniskillen, Tuesday, 17 October, 8.30 p.m., Representative's report, film strip, and supper.*

GLASGOW DIVISION.—Tuesday, 17 October, visit to Ravenscraig Steel Works, Motherwell. Transport will leave Glasgow Regional Office at 5.30 p.m.*

GRIMSBY DIVISION.—At Humber Royal Hotel, Thursday, 19 October, 7.30 for 8 p.m., annual dinner. Guests are invited.*

HARROGATE DIVISION.—At Cairn Hotel, Tuesday, 17 October, 8.30 p.m., general meeting to discuss Presidency for 1970-1.

MID-GLAMORGAN DIVISION.—(1) At Redcroft, 30 Dinas Baglan Road, Port Talbot, Friday, 20 October, 8 p.m., wine and cheese party in aid of R.M.B.F.* (2) At Margam Abbey, Sunday, 22 October, 3 p.m., St. Luke's Day service.

MIDLAND BRANCH.—At Lecture Theatre, General Hospital, Birmingham, Thursday, 19 October, 8 for 8.15 p.m., clinicopathological section meeting, Dr. B. L. Pentecost, Dr. N. M. C. Mayne: "Coronary Care Units in Treatment of Myocardial Infarction."

MONMOUTHSHIRE DIVISION.—At Belle Vue Hotel, Newport, Thursday, 19 October, 7.30 for 8 p.m., dinner and symposium meeting: "Peripheral Arteriovascular Disease."*

NORTH MIDDLESEX DIVISION.—At Committee Room, North Middlesex Hospital, Tuesday, 17 October, 8.30 p.m., film: "Confidence by Choice" (contraceptive methods). Mr. A. Davis will open the discussion. Followed by buffet supper.*

NORTH OF ENGLAND BRANCH.—(1) At Royal Victoria Infirmary, Newcastle upon Tyne, Thursday, 19 October, 7 for 7.30 p.m., symposium by Dr. I. Kolvin, Mr. L. A. Gane, Mr. J. Gittins: "The Delinquent Child." (2) At Five Bridges Hotel, Gateshead, Saturday, 21 October, 7.15 p.m., annual meeting; 7.30 p.m., reception and dinner.

NORTH STAFFS DIVISION.—At Medical Institute, Hartshill, Wednesday, 18 October, 8.15 p.m., Mr. S. Bender: "Sex Hormone Therapy in General Practice."

OLDHAM DIVISION.—At Union Club, Oldham, Monday, 16 October, 9 p.m., B.M.A. lecture by Professor C. J. Polson: "External Signs of Injury."

PORTSMOUTH DIVISION.—(1) At the Cathedral, High Street, Sunday, 15 October, 11 a.m., St. Luke's service. (2) At Medical Centre, St. Mary's Hospital, Thursday, 19 October, 8.30 p.m., Dr. J. D. Pollitt: "Depression." (Preceded by supper, 7.45 p.m.)*

REDBRIDGE AND STRATFORD DIVISION.—At East Ham Memorial Hospital, 21-22 October, week-end general postgraduate course for general practitioners. Applications should be made to Dr. J. B. Enticknap at the hospital.

RICHMOND DIVISION.—At Watney's Brewery, Friday, 20 October, 8.15 p.m., meeting on "Road Traffic Act Provisions and Blood Alcohol Levels in Drivers." Speaker, Dr. B. M. Wright.

SHROPSHIRE AND MID-WALES BRANCH.—At Shrewsbury Medical Institute, Wednesday, 18 October, 8.30 p.m., annual general meeting.

SOUTH LANCASHIRE AND EAST CHESHIRE BRANCH.—At St. Ann's Church, St. Ann's Square, Manchester, Sunday, 22 October, 6.30 p.m., annual St. Luke's Day service.

STOCKPORT DIVISION.—At new Postgraduate Medical Centre, Stepping Hill Hospital, Sunday, 22 October, 10.30 a.m., clinical meeting.

SWANSEA DIVISION.—At St. Barnabas Church, Sunday, 22 October, 11 a.m., St. Luke's Day service.

TOWER HAMLETS DIVISION.—At St. Andrew's Hospital, Friday, 20 October, 3 p.m., Dr. A. T. Brain: "Some Geriatric Topics."

TROWBRIDGE DIVISION.—At Lansdowne Grove Hotel, Bath, Saturday, 21 October, 8.30 p.m., dinner dance.*

WALSALL DIVISION.—At Three Crowns Inn, Tuesday, 17 October, 8.15 p.m., Professor J. M. Bishop: "Pulmonary Heart Disease."*

WEST BROMWICH AND SMETHWICK DIVISION.—At West Bromwich and District General Hospital Thursday, 19 October, 8.15 p.m., symposium on "Hypertension" and discussion.

WEST SUSSEX DIVISION.—At Burlington Hotel, Worthing, Wednesday, 18 October, 7 for 7.30 p.m., dinner meeting, Mr. N. C. Tanner: "Modern Trends in Gastric Surgery."*

WIGTOWNSHIRE DIVISION.—At King's Arms Hotel, Glenluce, Friday, 20 October, 7.30 p.m., Professor J. W. Dundee: "The Influence of Various Medicaments on the Course of Anaesthesia and the Relief of Pain."

Branch and Division Officers Elected

ABERYSTWYTH DIVISION.—Chairman, Dr. W. H. Beasley. Vice-chairman, Dr. A. Davies. Honorary Secretary and Treasurer, Dr. J. B. Lloyd. Assistant Honorary Secretary, Dr. J. Griffiths.

CITY OF DUNDEE DIVISION.—Chairman, Dr. J. M. Langlands. Vice-chairman and Chairman-elect, Dr. D. M. Green. Honorary Treasurer, Dr. J. Scott Innes. Honorary Secretary, Dr. W. T. M. Yeaman.

FURNESS DIVISION.—Chairman, Dr. J. E. Horrocks. Chairman-elect, Dr. T. S. Moore. Vice-chairman, Dr. J. M. Stuart. Honorary Secretary, Dr. P. Gardner. Honorary Treasurer, Dr. A. MacLeod.

HEXHAM DIVISION.—Chairman, Dr. L. R. Routledge. Vice-chairman, Dr. W. Gibson. Honorary Secretary and Treasurer, Dr. M. McKendrick.

HUDDERSFIELD DIVISION.—Chairman, Dr. W. Brown. Chairman-elect, Dr. A. L. G. Smith. Vice-chairman, Dr. H. W. Davis. Honorary Secretary, Dr. A. M. Barlow. Assistant Honorary Secretary, Dr. W. Brown. Honorary Treasurer, Dr. J. F. Tomlinson.

KENYA MEDICAL ASSOCIATION.—President, Dr. J. S. Nesbitt. Vice-presidents, Dr. I. J. Khosla, Dr. M. Y. D. Kodwawala. President-elect, Dr. I. J. Khosla. Honorary Secretary, Mr. Andrew Hicks. Assistant Honorary Secretary, Dr. P. R. Mehta. Honorary Treasurer, Dr. L. L. Ghelani. Assistant Honorary Treasurer, Dr. B. P. Patel.

LEICESTERSHIRE AND RUTLAND BRANCH.—President, Dr. E. T. James. President-elect, Dr. Dudley Gotla. Vice-president, Dr. E. W. Goodwin. Honorary Secretary and Treasurer, Dr. L. Mitchell.

NORTH-EAST SUFFOLK DIVISION.—Chairman, Dr. G. Clayton. Honorary Secretary and Treasurer, Dr. W. J. Wren.

ROCHDALE DIVISION.—Chairman, Dr. R. Mallinson. Vice-chairman, Dr. W. T. Gordon. Honorary Secretary and Treasurer, Dr. A. H. Michael-Phillips.

SUNDERLAND DIVISION.—Chairman, Dr. B. Gordon. Chairman-elect and Vice-chairman, Dr. P. Inman. Honorary Secretary, Dr. C. Nelson. Honorary Treasurer, Dr. B. Tindle.

SWINDON DIVISION.—Chairman, Dr. J. A. M. Ager. Vice-chairman, Dr. D. F. Alexander. Honorary Secretary and Treasurer, Dr. F. J. Lowe. Assistant Honorary Secretary, Dr. H. Barnard.

WEST LOTHIAN DIVISION.—Chairman, Dr. G. M. Dewar. Vice-chairman, Dr. A. F. Lang. Honorary Secretary and Treasurer, Dr. M. Gardiner. Assistant Honorary Secretary, Dr. J. Callander.

WEST NORFOLK DIVISION.—Chairman, Dr. R. S. McKelvey. Chairman-elect and Vice-chairman, Dr. Humphrey Booth. Honorary Secretary, Dr. J. H. Ballantyne. Honorary Treasurer, Dr. R. V. Smith.

YORK DIVISION.—Chairman, Dr. A. I. MacLeod. Chairman-elect and Vice-chairman, Mr. C. Smith. Honorary Secretary and Treasurer, Dr. M. A. Wilson.

Scottish Council

By a large majority the Scottish Council approved the principle that charges might be made to non-members for certain services rendered them by the B.M.A. The Scottish Council was told that not enough money was provided for the ambulance service in Scotland.

At a meeting of the Scottish Council in Edinburgh on 3 October Dr. JOHN RIDDELL was re-elected chairman and Dr. MARY ESSLEMONT was re-elected deputy chairman.

The Chairman welcomed 14 new members. He pointed out that, while the Scottish General Medical Services, Public Health, and Hospital Medical Services Committees dealt with their special problems, the Scottish Council had an important part to play in getting agreement among all sections of the profession and in trying to reach conclusions acceptable to all parties.

It was reported that Dr. D. M. Baxendine had agreed to represent the Scottish Council on the Committee on Welfare of the Disabled of the Scottish Council of Social Service.

Car Parking

Copies were received of letters from the Scottish Development Department on the subject of parking concessions for doctors. They were to associations of local authorities and the Scottish Association of Executive Councils asking for their views on the Secretary of State's suggestion that doctors should be given recognition in parking schemes and that "Doctor" markings on the roadway near doctors' consulting-rooms should be authorized. The scheme suggested for road markings was broadly similar to the one which operated in the Westminster area in London.

Dr. W. W. FULTON said that representatives of the Scottish Development Department had said originally that the Secretary of State might well be more ready to give concessions, since he was also responsible for the National Health Service in Scotland. There was, however, no direct record that the question of road markings would be raised with chief constables. One of the letters stated that traffic wardens had the same powers of discretion as police constables, but Dr. Fulton questioned whether that was true in parking-meter zones. It must be quite clear where the powers of discretion began and ended. He said that the principle of one marking per consulting-room or surgery was no longer appropriate as the numbers in group practices increased. He thought it should rest with the B.M.A. and not the local authority to decide whether a roadway marking was justifiable.

Organizational Matters

A request was considered from the Organization Committee that the size of committees and the appointment of subcommittees should be reviewed. The Scottish Council found that "it could offer no recommendation to the Council" on this matter, since the Scottish committees were as small as was compatible with adequate representation and the smaller committees involved little expenditure.

Consideration was then given to the question of whether non-members should be charged for services provided by the Association.

Dr. J. E. MILLER said that he thought it probable that much time was given by B.M.A. staff to non-members. He thought there was a need for a membership card which would have to be produced or its number quoted whenever a service was requested. Other organizations adopted that method successfully. Dr. C. C. LUTON supported Dr. Miller, and said it was an important recruitment issue.

Dr. C. J. SWANSON disagreed with Dr. Miller and pointed out that the B.M.A. was there to promote the medical and allied sciences and interests of the profession. That non-members should take advantage of the B.M.A.'s services was between them and their consciences. It was all very well to have differential charges for material things such as car badges, but the high traditions of the Association should not be interfered with.

Dr. E. R. C. WALKER supported Dr. Swanson, and said that in his experience the use of the Association's Scottish Office by non-members was relatively slight. To be exclusive, he said, was a mistake.

Dr. MILLER said he accepted that much of the Association's work benefited everybody. When he was honorary secretary of the Glasgow Division non-members had said to him, "What can the B.M.A. do for me that it does not do for me as a non-member?" Those doctors, said Dr. Miller, had not got the conscience to which Dr. Swanson had referred "and therefore you cannot appeal to it." Schemes which had been mooted by the B.M.A. over the years and which should have been carried out had had to be abandoned for lack of money. "For donkey's years we have tried to encourage membership by working for non-members. The time has come to insist on membership," concluded Dr. Miller.

Dr. JOAN K. SUTHERLAND asked what services would be the subject of a charge, but the meeting decided against discussing the detail and to vote on the principle only.

It was moved by Dr. FULTON, with the agreement of Dr. MILLER, "That the Scottish Council approves the principle that charges may be made to non-members for certain services rendered to them by the Association where there is no charge for members."

The motion was carried by a large majority.

Road Safety Act

Reports were received of meetings held with the Scottish Home and Health Department and with the Crown Office to discuss the appointment of police surgeons and the arrangements and fees for taking blood specimens under the Road Safety Act, which was to come into force on 9 October.

Dr. SWANSON protested at the lack of public guidance given to doctors on what would be required of them. Doctors, he said, were in the dark on the matter. Dr. WALKER suggested that it might be necessary to set up a special committee to deal with problems associated with work for the police. Dr. G. H. HUGHES thought that such a matter should be dealt with on a U.K. basis—what was necessary was good liaison with London.

It was agreed that the Chairman and Scottish Secretary should look into the question of the appointment of a committee.

Ambulance Service

A request from the St. Andrew's Scottish Ambulance Service that the B.M.A. Scottish Office should arrange the appointment of two general practitioners to each of the six regional ambulance committees was agreed to.

Dr. FULTON, the general-practitioner representative on the central ambulance committee, suggested that when the ambulance service for a particular local medical committee area was under discussion the secretary of that local medical committee should be invited to the meeting. He said that unless the general-practitioner representation on these committees was increased all areas ought to have reasonably easy access to their appointed representatives. In the Western Region the area was very wide.

Dr. J. F. CAMERON said that in his area (Banff, Moray, and Nairn) a rotation of representation was arranged in appointing members to various committees, so that all local medical committees were represented in turn.

Dr. W. A. ROSS pointed out that local, and often very acceptable, ambulance arrangements were being replaced by central depots, and it was important that rural interests should be recognized by the appointment of a rural practitioner as one of the two general practitioners on each regional ambulance committee.

The Scottish Council supported that suggestion and also Dr. H. B. MURK's suggestion that deputies should be allowed when members could not attend meetings.

Dr. FULTON informed the meeting that not enough money was being provided for the ambulance service. That it was an expanding service was not recognized by merely increasing the financial allocation by 3½% each year.

The profession was constantly encouraging improvements in the hospital service (day hospitals, geriatric assessment units, etc.) and these placed increasing demands on the ambulance services. Those trying to run the ambulance service were suffering from a dearth of replacement vehicles. If the replacements were not ordered or were not forthcoming the money allocated could not be used, and any unused money each year went back to the Treasury.

Birsay Report

A report of comments by the Public Health Committee (Scotland) on the Birsay Report on General Medical Services in the Highlands and Islands was received.

Dr. CAMERON took exception to a recommendation by the Public Health Committee that relatives should not be employed as home helps. He said that in under-populated areas relatives were often the only people available. If they could not act as home helps there would be no home helps.

Dr. SWANSON agreed and said his subcommittee (the Highlands and Islands Practitioners Subcommittee) supported the Birsay Committee's recommendation that gave a blessing to relatives acting as home helps. Dr. Swanson informed the Scottish Council that a report by his subcommittee on the Birsay Report was to be presented to the G.M.S. Committee (Scotland) shortly. It was also stated that the Scottish Committee for Hospital Medical Services was awaiting a report on the subject from the Northern Regional Committee for Hospital Medical Services.

It was remitted to the Chairman to collect all the comments on the Birsay Report and to collate them in one document.

Committee Reports

Dr. SWANSON, in the absence of the Chairman of the G.M.S. Committee (Scotland), gave an account of its recent work.

The Secretary of State, he said, had been asked to allocate more money for health centres. Dr. Swanson also referred to a study of general practitioners working in hospitals, particularly those undertaking specialist duties unsupervised, and an unsuccessful attempt to get the lending power of the General Practice Finance Corporation extended to include equipment.

Reports were also received on the work of the Public Health Committee (Scotland) and of the Scottish Committee for Hospital Medical Services (*Supplement*, 14 October, p. 11). Under any other business, a suggestion by Dr. LUTTON that an annual one-page report on the work of the Scottish Council should be distributed was referred to the Chairman's Committee for consideration.

Dr. JOAN SUTHERLAND and others expressed dismay at the closing down of the Medical Practices Advisory Bureau in Edinburgh and its transfer to Glasgow. She was disappointed that there had not been full prior consultation with Scotland, and she was doubtful whether the move would effect economies.

Dr. SWANSON, speaking as one who practised neither in Edinburgh nor in Glasgow, said he saw a distinct advantage in having all the information concentrated in one bureau to which applications could be made.

Edinburgh Conference on Better Medical Care

"Better Medical Care—Which Road?" was the theme of a conference on 7 October arranged by the Edinburgh and South-east Scotland Branch of the B.M.A. and held in Edinburgh University. The conference was conceived along similar lines to a conference on "The Future of British Medicine" held in Newcastle upon Tyne in March (*B.M.J.*, 18 March, p. 693).

Present Position

Mr. GEORGE R. HODNETT, chairman of the Board of Governors, Royal Victoria Infirmary, Newcastle upon Tyne, opened the morning session of the conference, which was on the advantages and disadvantages of the present position. He said that the original requirements of the National Health Service had been underestimated. It had been thought that the health services could and should be paid for out of taxation, and the idea of private contribution had been swept aside. "Charity" and "means test" had become dirty words in the 1930s. However, when what had now developed was looked at not only had it not fulfilled expectations but the whole medical problem had become more difficult because of the progress of medical science, particularly on the hospital side.

At the moment there seemed to be no solution. Day-to-day directives received in hospitals gave the impression that all was going to happen, whereas the facts pointed to the probability that it would not happen. The Government in power could not move too far ahead of public opinion, particularly in respect of a problem which was either wholly or partly insoluble, unless that movement was going to justify itself in time for a general election.

Mr. Hodnett believed that the medical profession, which enjoyed and deserved the high regard of the community, should take a lead in forming public opinion. He asked the profession to consider whether below the Ministry there should be a medical board—a health board—which would be responsible for the recruitment, training, and employment of medical personnel and for the operation of the Health Service. It might possibly be under a Ministry which combined the social services, and which would have a pensions board, a health board, and an education board.

Mr. Hodnett believed that any Government should accept financial aid from any reasonable source. Old prejudices should be set aside and every means explored and pursued to raise funds from the public to supplement health programmes. He did not know how young qualified people who wanted

to go abroad could be prevented from doing so. He suggested for consideration, however, that young people in training might be under contract for a period of years, allowing within that period a secondment for overseas service and training. That would be followed by a return to Britain for a further period of service.

Administrative Musical Chairs

Dr. G. S. RIDDELL, medical officer of health for Fife, said the most significant factor to affect the National Health Service since its inception had been the seventh report of the Review Body and the Family Doctors' Charter. At the same time there had emerged a new interest in health centres. From these two factors organizational changes at local level which were possible within the existing administrative framework were starting to flow.

Radical changes in local administration at this stage might prove disadvantageous. The local authority services escaped some of the worst effects of central financial control and preserved some scope for independence, experiment, and diversity. Those were important and must not be lightly cast away for the sake of administrative expediency. The heart of the matter was not the administra-

tive structure but finance. Unless first an alternative, more flexible system of finance was evolved area health boards held no genuine promise of an improved Service and would merely involve playing administrative musical chairs.

Medical Aid System

Dr. C. C. LUTTON, general practitioner, Musselburgh, said that doctors were uneasy because the present medical system did not allow the high standard which should be possible. Unless there were changes in organization, finance, and use of the N.H.S. the standard would even deteriorate. The medical "industry" was inefficient and needed business analysis, so that the major effort could be properly organized and channelled to where it was most needed.

If patients wanted a better service then the world price for medical care must be paid, said Dr. Lutton. The time had come to examine the method of payment, because welfare regardless of need would eventually bankrupt any system. Most would agree that a free basic service was desirable, but on to this could be put various additional services to be paid for in proportion to use and income. Payments for prescriptions, consultations, appliances, and hospital board and lodging could be considered. Britain had a legal-aid system, so why not a medical-aid system, but on the basis of a health tax rather than a means-test system?

Dr. Lutton thought that the pattern of fewer general practitioners working in larger units would continue. Newly qualified doctors were reluctant to enter ill-equipped and under-capitalized practices. Meantime the promise by the Minister of Health of hundreds of health centres, for which money was not yet available, had effectively slowed down the improvements that many general practitioners were themselves undertaking. Failure to improve medical services further was likely to lead to a limited return to "insurance fund" private practice by those doctors who wished it and those patients prepared to pay.

Hospitals

Dr. J. G. M. HAMILTON, consultant physician, Edinburgh Royal Infirmary, said that twentieth-century medicine was rushing along so fast and expensively that it was difficult to conceive of enough money being made available for hospital services.

He criticized the closure of cottage hospitals—"those invaluable assets." Far from being abandoned, he thought that new ones should be created in towns and cities as well as in the country districts. There was no inherent professional reason why a general practitioner should not look after his own patient in his own hospital when that was practicable.

Dr. Hamilton said that the initial administrative and staffing problems which existed in the hospital service before 1948 were still there. They had been aggravated by the growing sense of frustration and unfulfilled dreams. They had not been overcome despite the flag-waving, fine words, and grand promises upon which the Service had been largely fed for nearly 20 years.

Dr. W. P. U. KENNEDY, hospital registrar, Edinburgh, argued that there was too "pussey-

footed" an attitude to specialization. Cardiac departments, for instance, were still expected to take their quota of admissions along with the other medical wards. How could they possibly fulfil both functions? Such departments should be accorded full specialty status.

He proposed a concept of a central specialist hospital providing for advanced diagnostic studies, research, and complex therapeutic facilities. Together with the undergraduate and postgraduate medical schools for the region it could comprise a medical complex that could be the spiritual centre of the region. Its limbs would be the district general hospitals, providing a comprehensive hospital service for their own area. All hospitals would take part in teaching students and training their own medical staff. In every hospital much greater importance would be attached to the intensive-care area and to mobile teams equipped to deal with acute emergencies.

The Future

The opening speaker at the afternoon session, on the subject "The Future Organization of Medical Care," was Mr. ESMOND WRIGHT, M.P. for the Pollok Division of Glasgow, formerly professor of modern history at Glasgow University, and a member of the Committee on General Medical Services in the Highlands and Islands—the "Birsay Committee" (*Supplement*, 8 July, p. 23).

Mr. Wright submitted a 10-point programme for the medical profession. There must, he said, be more cottage hospitals and more hospices, especially in the Highlands and Islands of Scotland. The nurse-patient ratio in geriatric units must be "urgently improved." Also needed was an inspectorate of all geriatric units. There was also need to pay more attention to the crippling diseases rather than the killer diseases.

People were, in Mr. Wright's view, prepared to pay for medical services. That being so, there should be alongside and supplementary to the National Health Service a provision that allowed people to pay extra. Health insurance premiums should be tax deductible. He saw no reason why health insurance should not be regarded as important as life insurance.

In a "Common Market" world Mr. Wright thought the medical profession should be far more international in its recruitment than it had been. It was absurd to leave general practitioners to work in isolation. They should be encouraged to work in health centres.

Medical Organization

Mr. A. R. HOWIE, clerk to Renfrew County Executive Council and former secretary of the Scottish Association of Executive Councils, said that the sense of frustration among general practitioners arose less from the changed attitudes of patients than from the knowledge that patients must be aware that this was the one branch of the Service which, because of a lack of forward planning, could not join fully in the general surge forward in the practice of modern scientific medicine.

There was urgent need to change the existing organizational structure to create a sense of unity of purpose within the profession and an interchange of personnel within the Service that would stimulate the maintenance of skills at the highest level. It was doubtful whether the proper answer had yet been produced, and the profession must do some serious self-questioning and define the place of the general practitioner in a unified National Health Service. The most suitable organizational arrangements would then be apparent.

Dr. E. R. C. WALKER, former Scottish Secretary of the B.M.A., said that ignorance of the history of medical organization was one of the main reasons why there was so much confusion and so many conflicting ideas about the future. For generations doctors had taken an active part in promoting measures to improve the medical care of the people. They were, however, increasingly coming to realize that changes in the conditions under which medicine was practised, no matter how necessary and desirable they might appear to be, could carry with them the risk of defeating the very ends for which they were made. Others beside doctors were also coming to realize that.

Any experiment that had been in operation for nearly 20 years and had not obviously proved successful ought to be the subject of a thorough and dispassionate evaluation, said Dr. Walker. An inquiry by a Royal Commission or by some other procedure into the N.H.S. was clearly the first step towards better medical care.

Financing Medical Care

Opening the last session of the conference, on "The Financing and Administration of Medical Care," Mr. ARTHUR SELDON, editorial director of the Institute of Economic Affairs, said that, despite rising living standards, politicians had failed to raise the percentage of national income apportioned to the Health Service. In 1950 it was 4%, in 1961 4.1%, and in 1966 again 4.1%.

As a method of financing medical care the experiment of the Health Service had failed, and after 20 years it was time the failure was recognized. There had been little hospital building before 1962. Hospital staffing had changed so much that in the main categories there were 6,800 home-born and 5,300 overseas-born doctors. To reach the 5 to 6% of the national product spent by other countries £350m. to £550m. more would have to be raised in taxes. Even if that could be done it was childish to suppose that all that vast sum could go on the N.H.S. and none on education, on housing, or on other social services. To increase expenditure on the N.H.S. by 25% something like £2,000m. in taxation would have to be raised. No one in his right mind would give that solution a second thought.

Professor JACK WISEMAN, director of the Institute of Social and Economic Research at York University, said that the proposition that if those willing to pay more were allowed to they would attract the services of "too many" doctors and that the standards of service provided for others must inevitably fall was a blinkered view of society and the nature of the economic problem. If the Government's present position as the sole purchaser of general-practitioner services

enabled it to exploit them in the short term, then its longer-term consequences must be to reduce the supply of doctors more efficiently than any consumer-oriented scheme would.

Dr. IVOR M. JONES, chairman of the B.M.A.'s Private Practice Committee, said that health insurance should become compul-

sory in the foreseeable future. But in return for their premiums patients should be free to avail themselves of all or any of the relevant benefits and to supplement such benefits if they choose to do so. Administratively there should be some decentralization of the existing structure. The establishment of regional

or area health boards, along the lines advocated by Sir Arthur Porritt, would not only assist the integration of medical services and eliminate unnecessary duplication but could promote healthy competition between the regions and permit some degree of flexibility between them in their financial arrangements.

Committee on Overseas Affairs

There are to be discussions with the Ministry of Overseas Development on how retired British doctors might help developing countries by serving for short periods in some capacity. The value of service overseas by young British doctors is said to be beginning to be recognized by appointment committees in Britain, but not universally so. The Ministry of Overseas Development wants to know of any cases in which a doctor has been resettled at a disadvantage after temporary service abroad, and the Committee is pointing out to the Ministry that it is advisable for young doctors to go overseas on secondment rather than to take an appointment. Sir John Bruce, Regius Professor of Clinical Surgery, Edinburgh University, has been appointed to the first travelling fellowship of the Commonwealth Medical Association.

The Committee on Overseas Affairs held its first meeting of the session on 6 October. Professor D. E. C. MEKIE was re-elected to the chair.

World Medical Association

The Committee considered a letter from the Secretary-General of the World Medical Association asking for the support and co-operation of member national medical associations in its drive for individual associate members. Among the advantages of individual associate membership was the receipt of the *World Medical Journal*.

Dr. M. WARE, Editor of the *British Medical Journal*, said that the W.M.A. was asking national medical associations to distribute to their members for a period of two to three years the English-language edition of the *World Medical Journal* and to pay the cost. Some national medical associations were already doing this. The matter was being looked into in Britain, but if it were done one of the advantages of associate membership of the W.M.A. would go, because every member of the B.M.A. would get the *World Medical Journal*.

Mr. J. R. NICHOLSON-LAILEY said that in 1966 the W.M.A. had managed to balance its budget and produce a small surplus of about \$20,000, but this had been possible only because the American Medical Association was providing \$40,000 a year for five years to tide the W.M.A. over the loss of revenue caused by the dissolution of the American Supporting Group. It was only by increasing individual associate membership that this loss could be made up. The operation of the tax laws in the U.S.A. made associate membership more attractive there than in Britain.

Sir CLEMENT PRICE THOMAS said that numerous associate members would provide a better solution to the financial problems of the W.M.A. than the distribution of the *World Medical Journal*.

The Committee agreed to consider the matter again when there was more information available on the implications of the W.M.A.'s request.

Report on Assembly

Dr. D. P. STEVENSON, Secretary of the B.M.A., reported on the 21st World

Medical Assembly, at which he had been elected to the W.M.A. Council. He said that for the first time there had been a substantial surplus on the year's accounts. He thought there might still be financial difficulties in the future, but support had been received from the American Medical Association.

Dr. Stevenson said that consideration was being given to the problem of national medical associations that did not pay their dues to the W.M.A. It must be recognized, he said, that some associations were poorer than others, and it was for the privileged to try to look after the underprivileged. However, it was hoped that a solution to this problem would be found.

Another of the decisions taken at the Assembly had been that the Swiss Medical Association should in future act as the liaison between the W.M.A. and other international organizations. Since many of these were based on Geneva, this would be convenient and economical.

The Assembly, said Dr. Stevenson, spent much time debating the medico-legal aspects of the "moment of death." The Council of the W.M.A. was going to study the matter and would be asking national medical associations to co-operate. Another major decision of the Assembly had been that the W.M.A. should organize a fourth conference on medical education. The subject would be "Medical Education: A Collective Responsibility," and it would be held in Europe in 1972. The Council of the W.M.A. was anxious that national medical associations should support the conference, and they would be asked shortly to nominate a member to serve on the organizing committee and to put forward the names of speakers.

Supporting Group

It was reported that the British Supporting Group of the World Medical Association had made certain changes in its constitution. An important part of the work of the group consisted in sending used medical journals to hospitals or individual doctors in developing countries. The group wished to carry on this work.

The Overseas Committee supported the continuance of the Supporting Group and the changes in its constitution.

Overseas Conference

Dr. D. L. GULLICK, Under-Secretary, said that at the overseas conference in Bristol (*Supplement*, 29 July, p. 101) the difficulties sometimes encountered by postgraduates coming to the United Kingdom from overseas had been discussed. Since then a letter had been sent to all B.M.A. Branches and independent national medical associations in the Commonwealth drawing their attention to this matter and asking them to inform B.M.A. headquarters of any difficulties their members might have experienced.

Dr. C. B. VAUGHAN pointed out that probably doctors from overseas who were already working in this country were in a better position to report on the problems they had encountered than those still in the Commonwealth.

Service Overseas After Retirement

The Committee discussed a resolution of the Annual Representative Meeting 1967 proposing that the Council should inquire into the desirability of setting up a scheme in which retired doctors could offer their services to work for a period in one of the developing countries.

Dr. J. M. LISTON, medical adviser to the Ministry of Overseas Development, said that the idea that older doctors could offer something to countries overseas was a good one. However, there were difficulties. One was the period for which they could work. If it was, say, for two years that would be useful to the country concerned. If for three months it would neither be useful nor economically feasible.

The sort of vacancies the Ministry was asked to fill, said Dr. Liston, included a number for so-called general-duty medical officers, and it was unlikely that a doctor aged 60 to 65 who had retired from practice in Britain would be fitted for that type of work. But there were other posts—in hospitals, for instance—in which there was a shortage of doctors in the middle and lower grades. The opportunities in the specialist fields were limited. Dr. Liston suggested that members of the Committee and of the Ministry should meet to work out a scheme.

The CHAIRMAN agreed that it would be useful to discuss a scheme with Dr. Liston's department. The B.M.A. could also, through

the Commonwealth Medical Association, inform doctors overseas of the type of help available to them if they required it.

Dr. R. L. LUFFINGHAM said that Dr. Liston had talked about sending doctors to salaried posts overseas. But surely that was not what the Committee envisaged. He believed that its suggestion was that doctors should go out to supplement the existing services, for which they would receive some sort of honorarium plus expenses. Such posts would not be found in Dr. Liston's list. It should be made known in the developing countries that there were various specialists willing to give their services for an honorarium and expenses. Dr. Luffingham said the Committee was not interested in career posts. Three months was perhaps too short a time, but two years for a doctor aged 60 to 65 might be too long. There should be close links with overseas medical associations to find out what posts there were which were outside the category the Ministry of Overseas Development had in mind.

Dr. VAUGHAN suggested that the doctors the Committee had in mind could be particularly useful in public health, port health, school, and mental health work.

Mr. R. V. COOKE, the President, suggested that fewer senior men were now required in the developing countries, because posts in those countries were being filled by their own nationals.

Dr. LISTON said that there was no evidence of a lessening of the overall demand in the overseas territories. The demand always kept ahead of the available resources.

The Committee agreed with Dr. Liston's proposal that its representatives should meet those of the Ministry of Overseas Development.

Secondment Overseas

The Committee considered a letter from the Ministry of Overseas Development which stated that it had always been concerned that doctors who served temporarily in the developing countries should not suffer any setback in their careers on their return to Britain. The letter continued, "At present we have little evidence that doctors are resettled at a disadvantage, and if any has come to your notice we should be very grateful indeed to have the details—not with a view to tackling any individual case, which I think would be beyond our powers at the moment, but in order to try to prevent similar occurrences in the future."

Dr. MARY ESSLEMONT said that she knew from experience that appointment committees turned down young men who had spent time in posts overseas and who had had much experience—far more than any young registrar could get in this country. They were turned down on the ground that they had not had "effective supervision." This was quite wrong, said Dr. Esslemont.

Mr. COOKE said that the Royal Colleges had sent out directives to all appointing bodies and to consultants that they should take account of service overseas when making appointments. He also emphasized that young doctors should go overseas only on secondment, because that ensured that a continuing interest was taken in their progress.

Professor F. E. STOCK said that it was now realized that there was considerable ex-

perience to be gained overseas, and in his own region there was no opposition to appointing to vacant posts doctors who had been employed overseas.

The CHAIRMAN suggested that in replying to the Ministry of Overseas Development the Committee should state that it was not persuaded that it was advisable for a young doctor to go overseas unless he was seconded to a post.

Commonwealth Medical Association

Dr. GÜLLICK reminded the Committee that the Commonwealth Medical Association had established a travelling fellowship (*Supplement*, 22 April, p. 21). It had now been agreed that Sir John Bruce, Regius Professor of Clinical Surgery, Edinburgh University, should visit certain African countries. A second fellowship was already being considered.

Overseas Undergraduates

The Committee received a report that the Committee on Medical Science, Education, and Research had suggested that in order to ensure that the principle of reserved places for overseas undergraduate students was implemented the matter might be referred to the deans of medical schools.

The CHAIRMAN said the number of overseas undergraduates in Britain had been cut down on the false assumption that the universities in their own countries would be able to give them a more appropriate education. But it was highly advantageous to have a certain number of foreign students in a university, and he thought that there should be places reserved for overseas students in British medical schools.

Dr. GÜLLICK said that there were certain Commonwealth countries, such as Sierra Leone and Cyprus, which had no undergraduate medical schools, and the result was that some of their undergraduates went to Moscow, because they could not get places in the United Kingdom.

Professor STOCK was uncertain about the wisdom of earmarking a certain percentage of places at the universities for overseas students. It would be better to make the needs of these students a reason for increasing the number of places and providing new medical schools.

Sir CLEMENT PRICE THOMAS said that that was shelving the problem until there were more medical schools. Britain should show its responsibility to those countries in the Commonwealth that did not have their own medical schools by providing a certain number of places for overseas students. It would then follow from that that it was the Government's responsibility to provide more medical schools.

Dr. VAUGHAN thought the Committee should recommend that some places should be kept for overseas undergraduates without committing itself to a percentage. Mr. COOKE said it should not be suggested that that had not been done. Some schools had kept places for overseas undergraduates as a matter of routine.

The Committee agreed that it was strongly of the opinion that there was great value in having a certain number of overseas students from Commonwealth countries, particularly those who had no medical school of their

own, but it appreciated the difficulty at the present time of implementing this policy.

Postgraduate Education

The Committee on Medical Science, Education, and Research had also suggested that in order to ensure that the principle of reserved training posts for overseas postgraduate candidates was put into effect the matter might be referred to the Committee of Postgraduate Deans.

The CHAIRMAN pointed out that any really serious postgraduate student could usually be accommodated. The idea of the reserved post would not work because each individual student came with a different requirement, and there could not be reserved posts in all departments.

Among the matters discussed at the Overseas Conference was the difficulty experienced under the Commonwealth Immigrants Act by some Commonwealth doctors wishing to enter the United Kingdom for postgraduate education.

Dr. R. A. PALLISTER, medical director, Commonwealth and International Medical Advisory Bureaux, explained that there was no problem for those students who were sponsored by universities. But many came independently. If they were Commonwealth doctors and they had an employment voucher they could be admitted to this country without difficulty and stay so long as they wished. The demand for these vouchers had increased, and there was a waiting list of more than a year.

A doctor who came without a voucher must come as a student or as a "working holiday-maker." He must have sufficient funds, like any other visitor, and his stay in the country was limited. If he wished to stay longer he had to obtain permission from the Home Office.

Dr. A. N. MATHIAS, Chairman of the Representative Body, asked why doctors had such a long wait for employment vouchers if their qualifications were acceptable to the General Medical Council. Dr. PALLISTER replied that the voucher was supplied by the Ministry of Labour. There were only a certain number for all skilled people, such as doctors and teachers, and they had to wait their turn. Dr. MATHIAS suggested that there might be a medical advisory committee which could be consulted in cases of difficulty.

It was agreed that Dr. Pallister should report to the Committee any cases of difficulty which came to his attention.

Fees for Colliery Emergencies

The B.M.A. has agreed with the National Coal Board that general practitioners who attend colliery emergencies should be paid £1 11s. 6d. for a single attendance not exceeding one hour between 8 a.m. and 8 p.m., and £3 3s. between 8 p.m. and 8 a.m. The fees for an "underground visit" will be £5 5s. for the first hour, with £2 2s. for each subsequent hour or part of an hour.

In the past the fees varied considerably in each area, and in some areas no fees were paid at all.

Opinions on Consultant Distinction Awards

The Representative Body of the B.M.A. resolved in 1966 that there should be a postal ballot of all consultants, senior hospital medical staff, and senior registrars to ascertain their views on merit awards for consultants.

On 1 June the B.M.A. sent out some 14,000 ballot papers to consultants, S.H.M.O.s, and senior registrars in the United Kingdom together with a covering letter, a memorandum of information on consultant distinction awards, and a business reply envelope. Subsequently any of these doctors who had not received the papers were asked to inform the Secretary (*Supplement*, 17 June, p. 176; 29 July, p. 108). The ballot paper invited answers to the following questions:

(1) What is your present grade in the hospital service?

(2) What is your specialty?

(3) What is your age?

(4) If eligible, are you the holder of a special distinction award?

(5) Do you support the continuation of special distinction awards (whether on the present or on some revised system)?

(6) Do you consider that the present system requires any change?

Answers of "Yes" or "No" were asked for to Questions 4 and 5, and "Yes," "No," or "Don't know" to Question 6. Those who answered "Yes" to Question 6 were asked (Question 7) to state briefly the change or changes they considered desirable.

The ballot papers did not require to be signed, and on receipt were separated from the enclosing envelopes which bore the names of the senders, so that when they came to be examined the identity of the voter was not available.

Results

The ballot closed on 30 September, and the Scottish Office and the Scottish Secretary of the B.M.A., who acted as returning officer, has issued the following information on the results.

The number of replies received was 7,349.

Valid replies were received from:

Consultants	5,889
Senior hospital medical officers	226
Senior registrars	940
	7,055

The remainder of the replies were invalid for the following reasons:

Not in above grades	22
No grading given	3
Retired	141
No identification on envelope	120
Spoilt	8
	294
	7,349

Of the 5,889 forms returned by consultants 2,066 were from consultants with distinction awards, 3,803 were from consultants without distinction awards, and 20 were from con-

sultants who omitted or refused to disclose whether or not they held an award.

Changes Considered Desirable

In an analysis of the comments of those who answered Question 7 Dr. Hadfield emphasizes that the information coming from the answers had no statistical validity and could show only trends of thought and a wide variety of ideas. Out of the valid replies 2,486 (35%) contained no comment. In

British Medical Association

Proceedings of Council

A special meeting of the Council was held on 14 October to consider: (1) a report by the Secretary on discussions with Medical Management Services Limited since October 1964; (2) reports from the Association's advisers; and (3) a report of the General Medical Services Committee.

Dr. RONALD GIBSON was in the chair.

G.M.S. Committee's Report

Dr. J. C. CAMERON presented the following report and recommendations of a meeting of the G.M.S. Committee held in B.M.A. House, Edinburgh, on 12 October.

Medical Management Services Ltd.

The G.M.S. Committee considered a report on the B.M.A.'s dealings with Medical Management Services Ltd. since 1964.

The Committee also considered the following resolutions passed by the Representative Body in July 1967, which had been referred to it by Council:

Resolved (as an instruction to Council): That this Meeting instructs our negotiating team to reopen negotiations immediately with the Ministry for the reimbursement of payments made to wives or dependants actually working as ancillary help; particularly in the case of those

who have secretarial or nursing qualifications.

Resolved: That this Meeting instructs Council to determine the commercial value of the work done in general practice by dependent relatives.

Resolved: That this Meeting instructs Council to determine immediately the number of dependent relatives working in general practice, their qualifications, and their geographical distribution.

Resolved: That this Meeting considers that any pension contributions paid on behalf of ancillary staff should be partially reimbursed by the Government, and further that these pension rights should be transferable to any Government employment.

The Committee decided to take the highest expert advice so that it could itself undertake a fact-finding survey into the employment of related and unrelated ancillary staff to be followed by a proper commercial evaluation of the services of the former.

The Committee is quite clear, however, that whatever action might be taken at this stage in this way it could have no beneficial effect on the outcome of the review upon which the Review Body is about to embark.

The Committee is confident that the Council will lend its full support to the way in which it has decided to give effect to the appropriate resolutions of the A.R.M. It has also had most careful regard to the considered views of counsel, and therefore recommends:

(1) That if M.M.S. proceeds with its stated intention of issuing a questionnaire to all general practitioners, and if as a result doctors inquire of the B.M.A. what their attitude should be to it, they should be advised to consult their own accountants and also be informed that their

answers can have no effect on the current deliberations of the Review Body.

(2) If M.M.S. in their circular should give the impression that their inquiry has B.M.A. backing steps should be taken at once to send a suitable letter to all general practitioners disclaiming any such support.

Resolutions of Council

After a lengthy debate in private the Council approved the report of the G.M.S. Committee, and it endorsed the Committee's decision to undertake a fact-finding survey into the employment of related and unrelated ancillary staff and a commercial evaluation of the services of related staff.

The Council also resolved as follows:

(1) That if Medical Management Services proceeds with its stated intention of issuing a questionnaire to all general practitioners, and if as a result doctors inquire of the B.M.A. what their attitude should be to it, they should be advised to consult their own accountants and also be informed that their answers can have no effect on the current deliberations of the Review Body.

(2) If Medical Management Services in their circular should give the impression that their inquiry has B.M.A. backing a suitable letter should be sent to all general practitioners disclaiming any connexion between that circular and the questionnaire to be issued by the British Medical Association.

(3) That the B.M.A. should not support Medical Management Services Ltd. at the present time.

Inner London Executive Council

In a foreword to the Annual Report of the Inner London Executive Council for the year ended 31 March 1967 Mr. G. F. Rowe, the chairman, writes that the council's services had undergone a major upheaval in recent months as a result of the new remuneration system for general practitioners. He thought the new methods of payment seemed to provide "a very satisfactory outcome for the doctors." In addition to an increase in their gross receipts they should derive considerable advantages from the arrangements for direct reimbursement of rent and rates on their practice accommodation. Mr. Rowe pointed out that doctors had often said money was not their first concern, and he thought this contention might be supported by the fact that several months after the new arrangements had been introduced 200 doctors out of some 1,500 whose main practices were in the council's area had failed to ask for reimbursement of their rent and rates.

London doctors were now showing "a keen interest in health centres." New health centres in Camden, Hackney, and Hammersmith had reached an advanced stage of planning, and the Grove Centre, Hammersmith, had been approved by the Ministry of Health. Twenty-three other possible projects were being considered. The planning of the health services in Thamesmead, the area of the Woolwich and Erith marshes to be developed by the Greater London Council for 60,000 people, had continued, and Mr.

Rowe paid special tribute to the work done on it by the General Practice Research Unit of Guy's Hospital.

Some Figures

The report states that the number of general practitioners on the Inner London Executive Council's medical list decreased during 1966-7 by 50 to 2,212. The number of patients included on general practitioners' lists during the year decreased from 3,465,685 to 3,445,379. Many people were said to have had difficulty in finding a doctor willing to accept them. At 31 March 1967 the average number of patients on a doctor's list, whether resident within or without the council's area, was 2,342. That compared with 2,238 in 1964, 2,290 in 1965, and 2,329 in 1966.

The council had inspected all proposed new surgeries, and the inspection was normally done by an officer of the council accompanied by an officer or member of the local medical committee. The Ministry of Health's standards of practice accommodation were applied as a guide, but with "considerable latitude" in view of the difficulties of finding accommodation in London.

By the end of March 716 claims for rent and rates for 853 surgeries amounting to £55,819 had been paid for the December quarter. Most of the claims were on an interim basis, but for 72 premises the district

valuer's assessment of a notional current market rent was received in time to pay on a permanent basis. Reminders were sent to 151 doctors who had not claimed their payment for the December quarter. By the end of the year 1,138 applications had gone to district valuers, and in 436 instances the current market rent, notional rent, or apportionment of the gross rateable value had been determined.

During the year there were 173 cases of attempts to obtain drugs by irregular means. There were 190 cases in the previous year. In 28 cases prescription forms were stolen from doctors' cars or surgeries.

Journal Committee Chairman

Professor Sir Alan Moncrieff was elected chairman of the Association's Journal Committee at its first meeting of the session on 11 October, in succession to Dr. J. G. M. Hamilton. Dr. Hamilton retired from the Committee at the end of last session. He had been 13 years in the chair.

Sir Alan Moncrieff has been a member of the Journal Committee since 1952, and before that he had been a member of its Publishing Subcommittee for many years, and chairman from 1950.

Armed Forces Committee

The Armed Forces Committee held its first meeting of the session on 9 October. Major-General J. C. BARNETSON was re-elected Chairman.

Dispute with Ministry

The CHAIRMAN reminded the Committee that since March the Association had withheld from the B.M.F. all advertisements for medical posts in the armed Forces, and that deans of medical schools had been informed that the B.M.A. could no longer recommend a career for doctors in the Services (*Supplement*, 1 April, p. 5).

These sanctions had been applied by the Association after the breakdown of the negotiations between the Government and representatives of the profession on the pay of doctors in the armed Forces.

Surgeon Commodore N. S. HEPBURN said that there was an overall shortage of doctors in the Navy, and it was worst among those with short-service commissions. Direct entry to short service, as opposed to ex-cadet entry, was falling off. The number of doctors transferring from the short-service list to the permanent list had also fallen off badly, and if this continued the position would become acute. The cadet entry continued to be satisfactory.

Surgeon Captain R. W. DUNCAN, also said that the problem had been that there were too few short-service officers. How-

ever, the Navy was now losing doctors from the regular corps. The short-service, non-specialist medical officers provided the majority of sea-going doctors, particularly in the smaller ships, and this was where sacrifices were now having to be made.

Colonel A. D. YOUNG said that the Army was facing the most serious situation in its history. A deficiency in medical officers had been increasing since 1962, and since then the number of medical officers who had voluntarily retired had also increased. The specialist services were generally at full strength, but a shortage of general-duty officers meant that the medical service was unable to meet all its commitments.

Air Vice-Marshal E. S. SIDNEY said that there was a current deficiency of 60 doctors in the Air Force, though the position was alleviated by the employment of civilian doctors. Air Force doctors thought there was no longer a rewarding career in the Services, at least financially. However, at present the Air Force was able to fulfil all its commitments. Surgeon Captain P. G. BURGESS wondered whether pay was the most important factor in recruitment. Air Vice-Marshal SIDNEY suggested that the uncertainty caused by the run-down in the armed Forces influenced the situation, and there was also loss of confidence in the present Government as an employer.

Colonel YOUNG, asked what doctors leaving the armed Forces did, replied that most

stayed in Britain and took jobs in the National Health Service with salaries equivalent to those they received in the Forces, and they also took their Service pension with them.

Reserve Army

Mr. R. MYLES GIBSON said that there was a serious lowering of morale in the Territorial Army and Army Volunteer Reserve. It was not a question of pay. There had been changes such as the reorganization of units and a consequent reduction in the number of senior appointments, and the rank and promotion structure had been adjusted.

The week-end training schemes, continued Mr. Myles Gibson, which were implicit in the new regulations for the reserve Army, occupying two week-ends a year, had not been entirely successful this year. Many busy general practitioners and hospital doctors had asked whether it was essential for them to attend the training camps. There was also the question of uniform, said Mr. Myles Gibson. The reserve Army still wore battle-dress, and as a result they felt "second-rate citizens" by comparison with their colleagues in the regular Army. He hoped those matters could be investigated.

Colonel YOUNG said that the next annual conference of the Territorial and Army Volunteer Reserve would be held in January 1968, when these points could be discussed.

Branch and Division Meetings to be Held

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

ABERYSTWYTH DIVISION.—At Old Maternity Hospital, Saturday, 21 October, 7.30 for 8 p.m., Dr. L. Davies: "Modern Methods of Investigating Heart Disease."

ASHTON, HYDE, AND GLOSSOP DIVISIONS.—At Deanwater Hotel, Woodford, Thursday, 26 October, 8 for 8.30 p.m., joint annual dinner and dance.●

BIRMINGHAM DIVISION.—At 36 Harborne Road, Edgbaston, Tuesday, 24 October, 8.30 p.m., jointly with A.B.P.I., symposium by Sir Derrick Dunlop (chairman), Professor O. L. Wade, Dr. S. Wand: "Prescribing Today."

BOURNEMOUTH DIVISION.—At Postgraduate Medical Centre, Friday, 27 October, 7.30 for 8 p.m., jointly with Bournemouth and District Law Society, buffet supper, Dr. C. T. Brown: "Antarctic Expedition."●

BROMLEY DIVISION.—At Bull Hotel, Chislehurst, Wednesday, 25 October, 7 for 7.30 p.m., jointly with Bromley and District Law Society, annual medical-legal dinner.●

BURNLEY DIVISION.—At Mackenzie Medical Centre, General Hospital, Friday, 27 October, 8.30 p.m., Dr. J. D. N. Nabarro: "Recent Trends in Diabetes Mellitus."

BURTON-ON-TRENT DIVISION.—At Stanhope Arms, Tuesday, 24 October, 7 for 7.30 p.m., jointly with B.D.A., dinner followed at 8.45 p.m. by Mr. P. Doherty: "Close Suppl. Dentistry."●

CITY DIVISION.—At Moorfields Hospital, City Road Branch, Tuesday, 24 October, 8.15 p.m., programme of illustrated lectures followed by discussion. (Preceded by buffet supper, 7.30 p.m.)

EALING DIVISION.—At Skyway Hotel, Thursday, 26 October, 8.30 for 9 p.m., annual dinner dance.●

EASTBOURNE DIVISION.—At Mansion Hotel, Tuesday, 24 October, 8.30 p.m., jointly with Eastbourne Law Society. Miss Celia Hensman and Mrs. Ann Hawker: "New Thinking on Alcoholism."

MAIDSTONE DIVISION.—At Medway Hotel, Friday, 27 October, 8 for 8.30 p.m., B.M.A. lecture by Professor A. Kekwick: "Obesity."

MEDWAY AND GRAVESEND DIVISION.—At Medway Postgraduate Medical Centre, Medway Hospital, Gillingham, Wednesday, 25 October, 8.30 p.m.; Mr. A. M. B. Tomkin: "Bleeding Peptic Ulcer."

MID-ESSEX DIVISION.—At Broomfield Hospital, Chelmsford, Saturday and Sunday, 28-29 October, 9.30 a.m., jointly with Chelmsford Medical Society, symposium: "Disabilities in Middle Age." (Applications should be made to the Secretary, Medical Academic Unit, Chelmsford and Essex Hospital.)

MID-GLAMORGAN DIVISION.—At Seabank Hotel, Porthcawl, Thursday, 26 October, 7 for 7.30 p.m., supper meeting, Chairman's address by Dr. J. Wynne Morgan, and election of representatives to Annual Representative Meeting.●

REDBRIDGE AND STRATFORD DIVISIONS.—At Forest Gate Hospital, 28-29 October, weekend postgraduate course in midwifery, gynaecology, and neonatal medicine for general practitioners. Applications should be made to the secretary of the hospital.

REIGATE DIVISION.—At Town Hall, Tuesday, 24 October, 8 p.m., short business meeting; 8.30 p.m., wine and cheese party for members and wives.

SOMERSET DIVISION.—At Board Room, Musgrove Park Hospital, Taunton, Thursday, 26 October, 8 p.m., four recent medical films and business meeting to elect representatives to Representative Body.

SOUTH BEDFORDSHIRE DIVISION.—At Luton Medical Centre, Tuesday, 24 October, 8.30 p.m., Boehringer lecture by Professor Sheila Sherlock: "Hepatic Cirrhosis."

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—At Glan Ely Hospital, Cardiff, Thursday, 26 October, 3 p.m., jointly with Cardiff Division, clinical demonstrations by Dr. John Pathy: "Rehabilitative Techniques for use with the Elderly."

SOUTHAMPTON DIVISION.—At Postgraduate Medical Centre, Wednesday, 25 October, 8 for 8.30 p.m., Mr. A. Lawrence Abel: "The Life and Times of John Hunter—Medicine 200 Years Ago." Followed by wine buffet. Guests are invited.●

SUNDERLAND DIVISION.—At Medical Society Lecture Room, Sunderland General Hospital, Tuesday, 24 October, 8.15 p.m., Mr. R. M. Kalbag: "Cervical Spondylosis."

BIRMINGHAM REGIONAL HOSPITAL MEDICAL SERVICES COMMITTEE.—At Queen Elizabeth Hospital, Tuesday, 24 October, 5.15 p.m., meeting.

LEEDS REGIONAL HOSPITAL JUNIOR STAFFS GROUP.—At Clinical Lecture Theatre, General Infirmary at Leeds, Wednesday, 25 October, 7.30 p.m., annual open meeting.

WELSH REGIONAL CONSULTANTS AND SPECIALISTS.—At 195 Newport Road, Cardiff, Sunday, 29 October, 2.30 p.m., annual general meeting, followed by meeting of the Committee.

British Medical Association

Joint Annual Meeting with the Australian Medical Association, Associated with the Third Australian Medical Congress, Sydney, 12-16 August 1968

President-Elect: C. O. F. RIEGER, C.B.E., M.B., B.S., F.R.C.S.ED., F.R.A.C.S.

President of Congress: R. H. MACDONALD, O.B.E., M.B., M.S., F.R.A.C.S., F.R.C.O.G.

Chairman of Scientific Committee: Professor JOHN LOEWENTHAL, M.B., M.S., F.R.C.S., F.R.A.C.S., F.A.C.S.

Secretary of Congress: NICHOLAS LARKINS, M.B., B.S.

Executive Officer of Congress: E. RUSSELL BELL, M.V.O., D.F.C., A.F.C., 135 Macquarie Street, Sydney, New South Wales.

Provisional Programme

The 136th Annual Meeting of the British Medical Association will be held in Sydney jointly with the Australian Medical Association and in association with the Third Australian Medical Congress. A cordial invitation to any B.M.A. member to attend the Congress is extended by its Executive Committee. This is only the second occasion on which the Association has met in Australia, the previous one being in Melbourne in 1935, before the formation of the Australian Medical Association.

The Joint Annual Meeting and Congress will be opened officially on Monday evening, 12 August, at the Town Hall, and it will be followed by the President's reception at the Trocadero.

It is expected that the social programme will include a civic reception, a State garden party, the President's dinner and other dinners, and a congress ball on the final evening.

The Henry Simpson Newland Oration will be given by Sir Hugh Ennor on Thursday evening, 15 August.

Church services will be held on Sunday morning, 11 August, and a Jewish service will be held on Saturday morning, 10 August.

Sporting activities have been arranged for Saturday afternoon, 10 August, and golf competitions will take place on Wednesday afternoon, 14 August.

Details of the Ladies' Programme will be announced later.

Registration

Registration for the Joint A.M.A.-B.M.A. Meeting will take place all day on Saturday, Sunday, and Monday, 10, 11, and 12 August, and the Scientific, Pharmaceutical, and Hobbies Exhibitions will be open daily from Monday, 12 August, to Friday, 16 August.

Advance registration forms together with hotel lists will be sent early in 1968 to B.M.A. members who notify the Secretary of the B.M.A. of their interest. The registration fee is £10 (sterling) for members and £4 sterling for associates (ladies or members of family aged over 18 accompanying members). The fee includes attendance at the various dinners on 13 August and at the Congress ball.

Other Meetings

The Joint Meeting will be preceded by the following meetings: Meeting of the Council of the Commonwealth Medical Association, Canberra, 1 to 2 August.

The World Medical Association, Twenty-second World Medical Assembly, Sydney, 5 to 10 August.

Hotel Accommodation

Tariffs for hotels at which reservations have been made for the Joint Meeting range from \$A4.75 (single) to \$A9.50 (double) in a private hotel and from \$A14.50 (single) to \$A18.50 (double) in a luxury hotel for room only. The "official hotel" is the New Wentworth Hotel. (Note: \$A=approximately 8s. sterling.)

Travel Arrangements

It is expected that members attending the Meeting will wish to visit places en route. The Medical Insurance Agency Travel Department has prepared an itinerary based on a round-the-world journey by air which can be offered to a group at an inclusive tour rate which is considerably less than the normal fare and cost of accommodation.

If sufficient bookings are received two groups will be arranged—one travelling to Sydney by an eastern route and the other by a western route. Starting from London, the group going by the eastern route will stay in Colombo (four nights); Singapore (two nights); Hong Kong (three nights); Sydney (nine nights); Auckland, New Zealand (four nights); Fiji (four nights); and San Francisco (three nights). The group going by the western route will take the journey in reverse. Both parties will meet in Sydney on 7-8 August. At all places to be visited, with the exception of Sydney, sightseeing tours will be organized, and whenever possible visits to medical institutions will be arranged.

The round-the-world tours will be offered at an inclusive cost to cover economy-class air travel by scheduled flights, transport to and from airports to hotels, accommodation in first-class or de luxe hotels with demi-pension, and local sightseeing tours, except in Australia.

Pending confirmation of certain local charges, the tours will be offered at an inclusive cost of approximately £600 for each person. A detailed itinerary with the exact costing will be available within the course of the next few weeks.

Those interested may write for details to the Medical Insurance Agency Travel Department, B.M.A. House, Tavistock Square, London W.C.1. (Tel.: 01-387-8486).

Provisional Scientific Programme

The theme of the Scientific Programme will be "A Review of Australian Medicine as at 1968," and the topics for the morning plenary sessions will be "The Advantages of Modern Technology," "Research—The Growing Edge," "How Many Doctors?," and "Back to Work." On three afternoons there will be group or section meetings arising out of the plenary sessions, but the meetings on Wednesday afternoon will be given to a free choice of subjects by sections.

There will be scientific and pharmaceutical exhibitions and daily showings of medical films. Closed circuit television will be shown on Monday and Thursday afternoons, 12 and 15 August.

Provisional Time-table

Saturday, 10 August

9 a.m. to 5 p.m.—Registration office and social centre open.
9.45 a.m.—Jewish religious service.
Afternoon.—Golf, racing, bowls, etc.
Evening.—Private arrangements.

Sunday, 11 August

9 a.m. to 5 p.m.—Registration office and social centre open.
10.30 a.m.—Robing for church services.
11 a.m.—Church services (Anglican, Presbyterian/Methodist, Roman Catholic).
Afternoon.—Private arrangements.

Monday, 12 August

9 a.m. to 5 p.m.—Congress office opens, registration office and social centre, Museum and Scientific Exhibitions, Photographic and Hobbies Exhibitions open.
10 a.m.—Opening of Trade Exhibition.
10.30 a.m. to 1 p.m.—Film Festival.
2 p.m. to 3 p.m.—Film Festival.
3.30 p.m. to 5 p.m.—Closed circuit colour television.
8.15 p.m. for 8.30 p.m.—Inaugural Meeting B.M.A.—A.M.A. and Congress. Joint Annual Meeting, opening of Congress, and Adjourned Annual General Meeting of the B.M.A., followed by reception.

Tuesday, 13 August

9 a.m. to 5 p.m.—Congress office and social centre open. Trade Exhibition, Museum and Scientific Exhibitions, Photographic and Hobbies Exhibitions open.
9.15 a.m. to 1 p.m.—Film Festival.
2 p.m. to 4.30 p.m.—Film Festival.
9.15 a.m. to 12.45 p.m.—Plenary Session: "Research—the Growing Edge." (1) Immunity: (a) "Basic Theory of Immunity," (b) "Application to Organ Transplantation," (c) "Application to

Autoimmune Diseases," (d) "Application to Cancer." (2) Panel Discussion on Immunity. (3) "Prophylaxis of Foetal Damage." (4) "Kuru."

2.15 p.m. to 4.45 p.m.—Group and section meetings.

7.30 p.m.—President's dinner (by invitation only).

7.30 p.m.—Other dinners.

Wednesday, 14 August

9 a.m. to 5 p.m.—Congress office and social centre open. Trade Exhibition, Museum and Scientific Exhibitions, Photographic and Hobbies Exhibitions open.

9.15 a.m. to 1 p.m.—Film Festival.

2 p.m. to 3.30 p.m.—Film Festival.

9.15 a.m. to 12.45 p.m.—Plenary Session: "How Many Doctors?" (1) "The Educational Challenge." (2) "Community Demand for Doctors in the Next Decade." (3) "Student Selection." (4) "Student Training." (5) "General Practice Training and Distribution." (6) "Specialist Training and Distribution." (7) Panel Discussion—"Does Present Training Meet the Need?"

Afternoon.—Golf competitions. Combined and individual sectional meetings.

Evening.—Private arrangements.

Thursday, 15 August

9 a.m. to 5 p.m.—Congress office and social centre open. Trade Exhibition, Museum and Scientific Exhibitions, Photographic and Hobbies Exhibitions open.

9.15 a.m. to 1 p.m.—Film Festival.

2 p.m. to 4.30 p.m.—Film Festival.

9.15 a.m. to 12.45 p.m.—Plenary Session: "Advantages of Modern Technology." (1) "Diagnostic Use of Isotopes." (2) "The Use of the Heart-lung Respirator." (3) "Dialysis." (4) "Heart Valves." (5) "Corneas." (6) "Biomedics." (7) "New X-ray Techniques."

2.15 p.m. to 4.45 p.m.—Groups and sections.

3.30 p.m. to 5 p.m.—Closed circuit colour television.

5 p.m.—Reception.

8.30 p.m.—Henry Simpson Newland Oration by Sir Hugh Ennor.

Friday, 16 August

9 a.m. to 5 p.m.—Congress office and social centre open. Trade Exhibition, Museum and Scientific Exhibitions, Photographic and Hobbies Exhibitions open.

9.15 a.m. to 1 p.m.—Film Festival.

2 p.m. to 4.30 p.m.—Film Festival.

9.15 a.m. to 12.45 p.m.—Plenary Session: "Back to Work." (1) "Legal Impediment." (2) "Government Responsibility." (3) "Psychiatric Impediment." (4) "Spinal Injuries." (5) "Cardiac Disorders." (6) "Industrial Action." (7) "Appliances."

2.15 p.m. to 4.45 p.m.—Groups and sections.

9 p.m.—Congress Ball.

Retirement Pensions

A revised Ministry of Health leaflet (S.D.M., 1967) published in April aimed to explain in more detail the special provisions of the N.H.S. Superannuation Scheme (England and Wales) for doctors and dentists in general practice set out in the National Health Service (Superannuation) (Amendment) Regulations, 1966 (*Supplement*, 10 December 1966, p. 222).

Paragraph 24 of the leaflet read: "The retirement pension is calculated as in the following Table, subject to a reduction to take account of the National Insurance pension."

Financial Years (i.e., years ended 31 March) During Which There was some Service as a Practitioner	Percentage of Remuneration Paid in Those Years
The first 10 such years	1½ per cent.
The second 10 such years	1½ per cent.
The third 10 such years	2 per cent.
The fourth 10 such years	2½ per cent.
Any such years after the fortieth	2½ per cent.

"For a practitioner with service before 15 December 1966 the pension will be 1½ per cent. of superannuable remuneration paid before 1 September 1962, and 1½ per cent. of that paid subsequently, if that would be to his advantage."

The Superannuation Division of the Ministry of Health has now issued a statement to clarify the words "subject to a reduction to take account of the National Insurance pension" in paragraph 24. The statement is as follows:

"The retirement pension payable to, and the contributions payable by, contributors to the National Health Service Superannuation Scheme are reduced (modified) to take account of retirement benefits payable under the National Insurance Acts. Practitioners who joined the scheme on 5 July 1948 have no reduction in their contributions or benefits. With a very few exceptions, all prac-

tioners who joined the scheme after 5 July 1948 will have their contributions and benefits reduced as follows: Contributions are reduced by £3 0s. 8d. a year for men and £3 5s. a year for women, except that these reductions are doubled in the case of practitioners who are regarded for National Insurance purposes as self-employed. Pensions are reduced from age 65 (men) or age 60 (women) by £1 14s. for each year of service. For the extremely small number of practitioners who participate in the graduated pension scheme there is a further reduction of superannuation contributions and pensions to take into account any graduated pension earned. If a practitioner has a payment in lieu of graduated National Insurance contributions made on his behalf he receives from the Ministry of Health's Superannuation Division a letter explaining the further reduction in his pension which this will entail."

Public Health Committee

An offer from the Management Side of Whitley Committee C in response to the public health medical officers' salary claim was considered to be unacceptable. Negotiations are to continue.

The eradication of brucellosis was once again discussed by the Public Health Committee. The Committee believes that the Ministry of Agriculture, Fisheries and Food's voluntary system of registration will not work and that there should be a phased slaughter scheme, and it doubts whether the cost of that would be prohibitive. Discussion is to continue on this and on the provision of lavatories on main roads. The B.M.A. wants the cost of providing main-road sanitary accommodation to fall more on central rather than local government.

The Public Health Committee held its first regular meeting of the session on 11 October. Dr. C. METCALFE BROWN was re-elected Chairman of the Committee, and Dr. C. D. L. LYCETT was elected Deputy Chairman.

Salary Claim

The Committee considered an offer from the Management Side of Committee C of the Medical and (Hospital) Dental Whitley Council in response to the public health medical officers' salary claim (*Supplement*, 23 September, p. 136). The Committee was informed of the views of the Staff Side of Committee C on the offer.

After a long debate the Committee agreed that the offer was unacceptable as it stood, and that negotiations should be continued.

Employment of Children

The Committee considered correspondence between the Education Welfare Officers National Association and the B.M.A. about the employment of children, and a memorandum on the subject by Dr. J. D. Kershaw.

It was recommended in the memorandum that children under the age of 14 should be medically examined if they were doing morning work, such as paper rounds. Dr. KERSHAW explained that that applied to morning and not to evening work, because the danger in morning work was that children might miss their breakfast.

Dr. A. MACARA pointed out that the children who did not have a breakfast were probably also those who did not go to bed early, because they came from badly organized homes. Many children aged 12 to 13 in good homes could do a morning or evening job without any ill effects.

The Committee decided to recommend the setting up of a joint committee with the Society of Medical Officers of Health to consider the matter of the employment of children.

Tees-side

Dr. J. T. A. GEORGE explained to the Committee that the regional constituencies of the Public Health Committee were based on the regional offices of the Association, but those members in the Tees-side Branch, and covered by the Tees-side Branch office of the Association, did not for Public Health Committee electoral purposes come within the Leeds or the North of England constituencies.

The Committee decided that members in this area could choose to be in whichever constituency they wished.

Sanitary Accommodation

The Committee discussed a letter from the Ministry of Health concerning sanitary accommodation on main roads.

The Association had drawn the attention of the Ministry of Health to what the B.M.A. considered to be the Ministry's lack of appreciation of the extent of the problem of providing enough lavatories on main roads. Much more money was needed from central Government for these facilities, the cost of which now fell heavily on local authorities. A figure of £61,000 had been estimated as the cost of providing two lavatories at each end of one main road. The Ministry had been prepared to grant only £3,000.

The letter from the Ministry stated that the Ministry of Housing and Local Government and the Ministry of Transport had been "puzzled" because £61,000 seemed to be an exceptional amount for two lavatories in a lay-by.

Dr. LYCETT explained that that figure included all the facilities, including access roads and half an acre of parking, and buying the land, etc. Unless it was done properly the job was not worth doing. There must be ways of disposing of refuse and satisfactory water points. Dr. Lycett hoped that the Association's policy would be to continue to press for more sanitary accommodation on main roads.

The Committee agreed that it should discuss the matter again in six months.

Brucellosis

The Committee considered an extract from the minutes of a meeting of the joint committee of the British Medical Association and the British Veterinary Association which discussed the eradication of brucellosis.

Gratification was expressed that the Ministry of Agriculture had made a start towards the eradication of brucellosis, and the joint committee had carried unanimously the following resolutions:

(1) That until brucellosis is eradicated from cattle measures should be taken to protect the human population. The most effective one would be the compulsory pasteurization of all milk from infected herds, and the prohibition of the sale of raw milk from any but accredited herds.

(2) That a financial incentive to farmers should be introduced in the form of a differential payment for milk from herds known by the Ministry of Agriculture, Fisheries and Food to be free from brucella infection.

These views had been forwarded to the Ministry of Health and to the Ministry of Agriculture, Fisheries and Food. The Ministry of Health had indicated that it had "no doubt that all milk should be heat treated before consumption." There were, however, certain practical difficulties in requiring the compulsory heat treatment of milk before sale. The Ministry had stated that "geographical difficulties in some parts of the country have made it impossible to achieve at an economic price the redistribution of heat-treated milk to remote areas. Some of

the difficulties may now be resolvable by the development of longer-keeping milks, and with this in mind we are taking a new look at the problems involved. Whether or not legislative action is found to be feasible we should like the public to be more aware of the potential dangers involved in drinking raw milk."

The Committee also considered a letter from Dr. George setting out the reasons why he believed this problem was being tackled in the wrong way. He said that the Government scheme was a voluntary scheme of registration. He did not think any voluntary scheme would work, because only a minority of farmers and not all veterinary surgeons appreciated the problems associated with eradication of the disease. On 26 July the Minister of Agriculture, Fisheries and Food had reaffirmed his faith in a voluntary scheme to begin with.

In Dr. George's view the Minister's concept of islands of brucellosis-free herds in a sea of infection was quite unrealistic. The spread of infection in cattle was extremely easy but often difficult to trace, and the Minister did not say how he would prevent the spread of infection at agricultural shows, in cattle transport, etc. Dr. George said that he doubted whether these infection-free islands would exist for long, let alone get bigger and coalesce.

Wrong Approach

The other reasons Dr. George gave for believing that the problem was being wrongly tackled were as follows. (1) There was no ban on the sale of infected beasts, and he doubted whether without such a ban any scheme would work. (2) There were no plans to circularize farmers with an explanatory brochure about brucellosis. The state of ignorance of many farmers was surprising, said Dr. George, and he saw no reason why a brochure should not be issued by the Ministry of Agriculture, Fisheries and Food. (3) Strain 19 vaccine was still the linchpin of veterinary control in spite of serious doubts about it. He knew of no reason why vaccine could not be purchased from Holland.

Dr. George stated in his letter that in his opinion the Ministry of Agriculture, which had at last accepted in principle the need for eradication of brucellosis, was so alarmed by the alleged cost of a slaughter scheme that it was mistakenly embarking on a lengthy voluntary scheme of registration. This might never work, said Dr. George, and would ultimately prove more costly than the obvious alternative of a phased slaughter scheme by areas with compulsory registration and a ban on the sale or movement of infected beasts. The amount of money available would dictate the speed of the area eradication scheme.

The Committee agreed to consider the matter further at its next meeting in the light of a memorandum from Dr. George.

H.M. Forces

Major-General J. A. D. Johnston, O.B.E., M.C., late R.A.M.C., has been appointed Honorary Physician to the Queen, in succession to Major-General M. H. P. Sayers, O.B.E., late R.A.M.C., retired.

Colonel C. Weymes, T.D., R.A.M.C., T. & A.V.R. has been appointed Honorary Surgeon to the Queen, T. & A.V.R., in succession to Colonel R. Barraclough, M.B.E., T.D., tenure expired.

Surgeon Commander A. I. MacDougall and Surgeon Lieutenant-Commander M. MacLean, R.N.R., have been awarded the Royal Naval and Royal Marine Forces Reserve Decoration.

Appointments.—Wing Commander T. C. Dobie, O.B.E. (deputy director of aviation medicine, Ministry of Defence, with acting rank of Group Captain); Wing Commander W. T. Fothergill (anaesthetic duties, R.A.F. Hospital, Cosford); Wing Commander I. M. Ogilvie (senior medical officer, R.A.F. Changi, Singapore); Wing Commander D. I. Fryer, O.B.E. (liaison duties with U.S.A.F., British Defence Staffs, Washington, U.S.A.).

ROYAL NAVY

Surgeon Captains E. H. Murchison, O.B.E., E. B. Martin and P. O'Brien have been placed on the Retired List.

Surgeon Lieutenant-Commander J. E. D. MacLaren has been placed on the Emergency List.

Surgeon Lieutenant A. M. Ashby to be Surgeon Lieutenant-Commander.

ARMY

Surgeon Colonel E. W. Hayward, O.B.E., late Royal Horse Guards, has retired.

Colonel A. L. J. Webb, late R.A.M.C., has retired on retired pay.

ROYAL ARMY MEDICAL CORPS

Major J. S. Templeton has relinquished his commission, and receives a gratuity.

REGULAR ARMY RESERVE OF OFFICERS

Major-General J. C. Barnetson, C.B., O.B.E., late R.A.M.C., having attained the age limit, ceases to belong to the Reserve of Officers, retaining the rank of Major-General.

ROYAL ARMY MEDICAL CORPS

Colonel J. R. Horler, T.D., from T.A., to be Colonel.

Major K. J. Dalgliesh has resigned his commission.

Major P. Esmonde, M.C., from Active List, to be Major.

Major D. L. Nicholls, T.D., from T.A., to be Major.

Short Service Commission.—Major J. D. Garry, from Active List, to be Major.

TERRITORIAL AND ARMY VOLUNTEER RESERVE

ROYAL ARMY MEDICAL CORPS

Majors J. S. G. Blair, T.D., and B. Devlin, O.B.E., have been granted the acting rank of Lieutenant-Colonel.

Major D. L. Hamblen, from T.A., to be Major.

Captain P. Hudgson has been granted the acting rank of Major.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major J. E. Dann Charles-Jones has resigned his commission.

TERRITORIAL ARMY RESERVE OF OFFICERS:

ROYAL ARMY MEDICAL CORPS

Major E. D. Edmondson has resigned his commission and has been granted the honorary rank of Lieutenant-Colonel.

Major H. J. Bell, M.B.E., T.D., has resigned his commission, retaining the rank of Major.

Majors G. R. Fryers and H. J. Fisher have resigned their commissions.

Captain (Honorary Major) J. C. Fletcher, T.D., has resigned his commission, retaining the honorary rank of Major.

ROYAL AIR FORCE

Group Captain E. W. R. Fairley has retired. Wing Commanders A. B. Goorney, A. M. Kingon, M.B.E., and E. R. Griffiths, O.B.E., have retired.

Wing Commanders P. J. Grant and W. A. Crawford, O.B.E., have retired at their own request.

Squadron Leaders A. C. MacLachlan, C. C. G. Rawll, D. A. V. Bearblock, I. G. Currie, J. Cottam, A. F. Hignell, and M. H. Rogers to be Wing Commanders.

Squadron Leaders S. B. Lydon, R. J. Wrighton, R. P. Christian, and G. Mackie have been transferred to the Reserve.

Flight Lieutenants G. L. Smith, J. G. Paterson, and I. Chorlton to be Squadron Leaders.

M. S. Hughes to be Squadron Leader.

Association Notices

Diary of Central Meetings

OCTOBER

- 31 Tues. G.M.S. Committee Hospitals Working Group, 12 noon.

NOVEMBER

- 1 Wed. Chairman's Subcommittee (Full-time Medical Teachers and Research Workers Committee), 10 a.m.
1 Wed. Annual Meetings Committee, 12 noon.
1 Wed. Liaison Committee with the Royal College of General Practitioners (at Royal College of General Practitioners, 14 Princes Gate, London S.W.7), 4.30 p.m.
2 Thurs. G.M.S. Planning Working Group on Medical Care in Rural Areas, 2 p.m.
3 Fri. Ophthalmic Qualifications Committee, 1 p.m.
3 Fri. Assistants and Young Practitioners Subcommittee (G.M.S. Committee), 2 p.m.
3 Fri. Common Market Committee, 2 p.m.
3 Fri. Ophthalmic Group Committee, 2 p.m.
7 Tues. G.M.S. Committee (Scotland) (at 9 Lynedoch Crescent, Glasgow), 10.30 a.m.
7 Tues. Forensic Medicine Subcommittee (Private Practice Committee), 2 p.m.
8 Wed. Joint Formulary Committee, 10.30 a.m.
8 Wed. Charities Committee, 2.15 p.m.
14 Tues. Standing Subcommittee (Central Ethical Committee), 11 a.m.
14 Tues. G.M.S. Disciplinary Machinery Working Group, 2 p.m.
15 Wed. Committee on the Mental Health Act, 10.30 a.m.
15 Wed. Rural Practices Subcommittee (G.M.S. Committee), 2 p.m.

DECEMBER

- 13 Wed. Journal Committee, 2 p.m.

Branch and Division Meetings to be Held

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

CHESTERFIELD DIVISION.—At Grosvenor Rooms, Friday, 3 November, 8.30 p.m., Mr. P. D. Trevor-Roper: "Influence of Eye Diseases on the Artist" (illustrated). Followed by buffet supper.●
CITY OF EDINBURGH DIVISION.—At 7 Drumsheugh Gardens, Thursday, 2 November, 7.30 for 8 p.m., dinner. Guest of honour, Mr. Ludovic Kennedy.

CREWE DIVISION.—At Crewe Arms Hotel, Wednesday, 1 November, 8 p.m., annual general meeting.

DUMFRIES AND GALLOWAY DIVISION.—At Cresswell Maternity Hospital, Dumfries, Sunday, 5 November, 3 p.m., B.M.A. lecture by Professor Thomas McKeown: "The Redesign of Medical Services."

DARTFORD DIVISION.—At Joyce Green Hospital Study Centre, Tuesday, 31 October, 8 for 8.30 p.m., B.M.A. lecture by Wing Commander P. Howard: "Space Medicine." Guests are invited.

EAST HERTS DIVISION.—At Recreation Hall, Queen Elizabeth II Hospital, Welwyn Garden City, Thursday, 2 November, 8 for 8.15 p.m., clinical meeting by Mr. D. Bedford.

GREENWICH AND DEPTFORD DIVISION.—At Miller General Hospital, Wednesday, 1 November, 7.30 p.m., clinical meeting.

HAVERING DIVISION.—At Nurses' Lecture Room, Oldchurch Hospital, Romford, Friday, 3 November, 8.30 for 9 p.m., Dr. J. Horder: "What General Practice Can Be."

HEREFORD DIVISION.—At Board Room, Hereford County Hospital, Wednesday, 1 November, 8.15 p.m., meeting to discuss lengthening time-lapse for outpatient appointments.

LANCASTER DIVISION.—At Postgraduate Medical Centre, Monday, 30 October, 7.30 p.m., residents' evening.●

LEWISHAM DIVISION.—At Medical Centre, Lewisham Hospital, Friday, 3 November, 8.30 p.m., The Forward Edge of Research I lecture by Dr. A. Macrae: "Viruses and Virus Disease."

LONDON DERRY DIVISION.—At Board Room, Altnagelvin Hospital, Derry, Friday, 27 October, 8.15 p.m., Mr. D. Baird: "Rheumatoid Arthritis."

MORPETH DIVISION.—At Queen's Head Hotel, Morpeth, Wednesday, 1 November, 7.45 for 8 p.m., dinner followed at 9.15 p.m. by B.M.A. lecture by Mr. N. Leigh-Taylor: "In Defence of Doctors."

PERTH BRANCH.—At Station Hotel, Wednesday, 1 November, 8 p.m., B.M.A. lecture by Professor Henry Miller: "Accident Neurosis."

RENFREWSHIRE DIVISION.—At Brablock Hotel, Paisley, Wednesday, 1 November, 8 p.m., B.M.A. lecture by Professor W. Gissane: "Road Accidents—their Prevention and Disposal."

SOCIETY OF MEDICAL OFFICERS OF HEALTH: WELSH BRANCH.—At B.M.A. House, Newport Road, Cardiff, Friday, 3 November, 6.30 p.m., inaugural meeting followed at 7.30 p.m. (approximately) by extraordinary general meeting.

SOUTH STAFFS DIVISION.—At Park Hall Hotel, Wolverhampton, Thursday, 2 November, 8.45 for 9 p.m., annual supper dance.●

SWANSEA DIVISION.—At Langland Bay Hotel, Friday, 3 November, annual dinner. Guest of honour, Dr. Ronald Gibson (Chairman of Council, B.M.A.).

TUNBRIDGE WELLS DIVISION.—At Spa Hotel, Thursday, 2 November, 8 for 8.30 p.m., annual dinner-dance.●

WALSALL DIVISION.—At the Hollies Club, Cannock, Thursday, 2 November, joint supper meeting with Cannock Medical Society, Dr. B. L. Pentecost: "Acute Coronary Care."

Correction

The statement in the report of the Armed Forces Committee (*Supplement*, 21 October, p. 24) that there was "loss of confidence [among potential recruits to the armed Forces] in the present Government as an employer" was wrongly attributed to Air Vice-Marshal E. S. Sidey. We apologize to Air Vice-Marshal Sidey for any inconvenience that may have been caused to him.

British Medical Association Proceedings of Council

Preparation of evidence for the next review of doctors' pay by the Review Body is well in hand. The B.M.A. has lost some 2,000 members owing to the New Zealand Branch becoming independent. What the Private Practice Committee regarded as the Association's lack of support for private practice and for Independent Medical Services Ltd. was criticized by the Chairman of the Private Practice Committee. The Council recognized that the policy of extending private practice and of giving all practicable support to I.M.S. had been approved by the Representative Body, and it resolved to urge "resolute and continuous action in this respect by all concerned." The action to be taken will be considered in the light of a memorandum to be provided by the Private Practice Committee. Negotiations on the public health medical officers' salary claim are continuing. A motion that the B.M.A. should not assist Independent Medical Services Ltd. in respect of those aspects of its discount trading scheme that overlap existing activities which it is already Association policy to support was lost.

A meeting of the Council of the Association was held on 25 October. Dr. RONALD GIBSON was in the chair.

The CHAIRMAN announced that the Harrogate Division had accepted the nomination of Sir John Richardson, Bt., as President of the Association for 1971.

The Chairman reported that all past-presidents, with the exception of one or two who were unable to attend, had given a dinner to Sir Arthur Porritt, Bt., to celebrate his appointment as Governor-General of New Zealand, and to wish him well (*B.M.J.*, 21 October, p. 181).

The Chairman said that Mr. J. R. Nicholson-Lailey, the Editor, the Secretary, and himself had attended the XX1st World Medical Assembly in Madrid (*B.M.J.*, 23 September, p. 795). Dr. Stevenson had been elected to the Council of the World Medical Association.

Annual Representative Meeting

The Council received protests from the Cornwall, North Bedfordshire, and Liverpool Divisions about the manner in which the Agenda had been dealt with at the Annual Representative Meeting at Bristol.

The first two Divisions complained that not all sections of the profession had received a fair proportion of the time available for debate, and speaking for the Liverpool Division Dr. G. E. CRAWFORD referred to the waste of time in the Representative Body discussing matters which had also been referred to the Conference of Representatives of Local Medical Committees. He thought that if the Conference were held at about Easter time there would be more time for Divisions to make themselves aware of what the Conference had decided, and they might not need to send up similar motions.

Dr. J. S. NOBLE, Chairman of the Organization Committee, stated that his Committee was seized of the problem. The duplication of debate was a waste of time, and every effort would be made to deal with the problem when the Committee made its report on procedure.

Dr. A. SKENE suggested that it was not the duplication of debate that was the problem but rather the sense of unreality at the A.R.M. when matters were debated in the knowledge that they had already been debated by the Conference.

Dr. R. B. L. RIDGE pointed out that it would be impracticable to hold the Conference as early as Easter, because it would make the active part of the session far too short.

Dr. D. P. STEVENSON, Secretary, said that in future before the A.R.M. met every representative would receive a paper showing what action had been taken by the Conference.

Emigration

The CHAIRMAN reported that a letter had been received from the Ministry of Health informing the Association officially that the Department had decided to send a medical team to North America to encourage British doctors to return to work in this country.

Dr. J. E. MILLER said there was some misgiving among doctors that favourable treatment might be given to induce the doctors who had emigrated to return. The interests of those doctors who had stayed at home must be safeguarded.

Dr. A. N. MATTHIAS, Chairman of the Medical Practices Committee, gave Dr. Miller an unqualified assurance that general practitioners were appointed to practices on their merits, wherever they came from.

Helicopter Ambulance Service

As the result of a letter from Dr. A. J. MACLEOD (Outer Isles Division) calling for the establishment of a helicopter ambulance service, the Council decided to refer the matter to the Central Committee for Hospital Medical Services with a strong recommendation that it should press for the establishment of such a service.

Welsh Committee

The Council agreed that the Welsh Committee be renamed the Welsh Council, and that it should function on the same basis as the Scottish Council, provided that the Association was not involved in extra expenditure.

The proposal was passed to the Organization Committee for the necessary arrangements to be made, including amendment of the by-laws.

Gifts

The Council received with gratitude the following gifts to the Association:

A silver tray, presented by the Immediate Past-President, Professor Hamid Ali M. Khan.

A silver porringer, originally presented to the late Sir Kaye le Fleming by the doctors of Dorset, and presented to the Association by his son, Mr. Christopher le Fleming.

A silver condiment set from Sir Arthur Porritt.

Sainsbury Report

The Council received the *Report of the Committee of Enquiry into the Relationship of the Pharmaceutical Industry with the National Health Service* (Sainsbury Committee).

Dr. STEVENSON said that much of the report was a matter for the industry, but there were some items to which the attention of doctors should be drawn. For instance, there was a recommendation that the Minister of Health should consider bringing the general medical and pharmaceutical services within the definition of "services of the Crown" for purposes of Section 46 of the Patents Act, 1949. Secondly, the report recommended that in future brand names should disappear. Drugs would be known by their approved name. Another recommendation dealt with the appointment of a Medicines Commission. There was a difference between the recommendation of the Sainsbury Committee and the Government's intended legislation. The Sainsbury Committee recommended a Medicines Commission which should be independent, and should be plainly seen to be independent. But according to the Government's White Paper on forthcoming legislation on the safety, quality, and description of drugs the Medicines Commission was to be appointed by the Minister of Health. Further, the Minister reserved the right to make regulations, and the Medicines Commission would be an advisory body and not necessarily an executive body.

The Association, said Dr. Stevenson, had been invited to comment on the legislation now proposed in the light of the recommendations of the Sainsbury Committee.

Dr. RIDGE drew attention to paragraph 53 of the White Paper, which referred to the Ministers having power by statutory instrument to prohibit the supply or sale of a drug. "Before we know where we are drugs that we want to use for our patients will be denied to us by statutory instrument," he said. "This is a serious threat to the clinical freedom of the clinician, and I ask Council to take note of it."

Dr. I. M. JONES said it should be made clear to the Government that the Council deplored the unseemly haste with which a Bill was being introduced before proper consultation on the Sainsbury Report with the profession. Furthermore, serious consideration should be given to the threats to clinical freedom contained in the Sainsbury Report and in the proposed legislation.

The Council agreed to ask the *ad hoc* Committee, set up under the chairmanship of Dr. A. Skene to prepare evidence to the Sainsbury Committee, to look into the matter, in consultation with representatives of the Joint Consultants Committee, and to report back to the Council at its next meeting.

Resolutions of A.R.M. 1967

The Council dealt with a number of resolutions adopted by the Annual Representative Meeting in 1967, and not referred to elsewhere in the agenda, and motions not considered by the A.R.M.

Review Body

The CHAIRMAN reported that the Review Body had requested the submission of evidence for the next review of remuneration by the end of October, and the preparation of evidence was well in hand. The Joint Evidence Committee was meeting in November.

In reply to Dr. D. J. PEREIRA GRAY, Dr. J. C. CAMERON, Chairman of the G.M.S. Committee, said that the G.M.S. Committee was finding out the position in relation to the employment of non-related staff by general practitioners.

Deputation to G.M.C.

The CHAIRMAN said that a deputation consisting of Dr. J. C. Cameron, the Secretary, and Dr. R. A. Pallister had had a useful meeting with the General Medical Council

to discuss the implications of the case of a Polish medical practitioner whose temporary registration on the Foreign List of the *Medical Register* had been withdrawn upon her marriage to a British citizen.

The President of the G.M.C. had made it clear that his council was under an obligation to implement the provisions of the Medical Acts and could not depart from them. Any departure from the present procedure would require amending legislation. The deputation obtained an assurance that when legislation was imminent the B.M.A. would be asked to join in further discussions.

Reports of Committees

The Council then proceeded to consider the reports of the Standing Committees.

Hospital Medical Services

Mr. H. H. LANGSTON presented the report of the Central Committee for Hospital Medical Services (C.C.H.M.S.). Mr. Langston said that it had given further consideration, at the request of the Council, to the representation of the special Groups on the Committee. It had examined the possibility of an alternative method of representation, but it had come to the conclusion that the only acceptable solution was to continue the direct representation of the Groups as it at present existed.

The Committee was not prepared to reduce the number of seats reserved for representatives of regional committees, and there was no other section of the Committee in which more than marginal reductions could be made.

Mr. Langston said there were a number of items in the hospital doctors' "Charter" on which it had been found possible to reach satisfactory agreement with the Ministry. There remained the important question of the structure of hospital medical staffing. Discussions on that matter were proceeding. There was no intention of putting anything into effect without a document being circulated to all interested parties and a full discussion taking place. It was hoped that a report would be issued before the end of the year.

Referring to the appointment of medical assistants, Mr. Langston drew attention to a recommendation of the Committee that a working party should be set up, consisting of Dr. G. E. Owen Williams (chairman), Dr. A. Allison, Dr. D. Lloyd Griffiths, and Dr. E. A. Harvey-Smith, to consider (1) the particular problems of the medical assistant grade at the present time, and (2) the representation of the grade within the Central Committee for Hospital Medical Services and associated bodies.

The Committee had agreed to a proposal of the Joint Consultants Committee "Group of Nine" and of the health departments that in future the medical assistant grade should be known as the "assistant grade" and that individual doctors in the grade should be known as "assistant surgeon," "assistant physician," etc.

The report was approved and the recommendation adopted.

Organization

Dr. J. S. NOBLE presented the report of the Organization Committee. He said that it had been digesting the enormous meal of the constitution debate at the A.R.M., and there was little to add. The Committee was considering with the Agenda Committee the procedure at the Annual Representative Meeting, and was about to consider, in conjunction with its representatives, the resolutions and memorandum from the East Yorkshire Branch which were referred to the Organization Committee.

Membership

Dr. Noble said that current membership was 66,573, which compared with 69,676 at the same period last year. The loss of some 2,000 owing to the New Zealand Branch becoming independent had to be taken into account.

Dr. CRAWFORD drew attention to a recommendation of the Organization Committee concerning deputations to Council. The Committee recommended that after the reception of the deputation its members should be invited to make a statement, and members of Council, at the discretion of the Chairman, might put questions to the deputation. The Chairman of Council, or at his invitation a member of Council, should reply to the points raised by the deputation, but if it appeared to the Chairman of Council that the matter should first be debated the deputation should be asked to withdraw until the debate was concluded.

Dr. Crawford suggested that the fact that a deputation needed to come to the Council rather indicated a lack of communication between the Council and the periphery, and it would be impossible to get improved communication in an exercise which looked like a monologue rather than a dialogue. In his view its whole purpose would be wasted if the deputation were not allowed to ask questions. He accordingly moved the reference back of the recommendation.

Dr. H. G. DOWLER seconded the reference back.

Dr. NOBLE said he could not conceive of an occasion when the Council would not give a fair hearing to a deputation, and it would be unlikely that Council would not give a deputation an opportunity of replying to points raised.

Dr. H. FIDLER opposed the reference back. The Council must make a stand about what

it would do. If the deputation wanted answers to its questions it would doubtless get them, and the Council should not go beyond that.

Dr. CRAWFORD said that if a deputation had taken the trouble to come to the Council there was something desperately wrong somewhere in communications, and it was very important to get the communications put right.

The motion to refer back the recommendation was lost.

The Council unanimously accepted a recommendation of the Organization Committee that Dr. D. Stenhouse Stewart, of the East Yorkshire Branch, should be admitted to the Roll of Fellows of the Association.

The report was approved and the recommendation adopted.

Private Practice

Dr. I. M. JONES presented the report of the Private Practice Committee.

He recalled that it was more than a year ago that the Council passed the following resolutions:

(a) That, as a matter of urgency, Council impress upon the profession the gravity of the present crisis facing the medical services of this country and the serious danger of the establishment of a complete Government monopoly in the provision of these services; In addition, Council strongly supports and urges, by all means at the Association's disposal, continuing and increasing practicable support of the profession for Independent Medical Services Ltd. to ensure its consolidation and expansion as a viable alternative medical service available to the whole community.

(b) That, as a matter of urgency, honorary secretaries of branches and divisions be invited to call meetings to publicize the scheme produced by Independent Medical Services Ltd.

Dr. Jones added that no doubt members of Council had read the report of the recent meeting of the Private Practice Committee (*Supplement*, 7 October, p. 9). It was an accurate report which truly reflected the attitude unanimously adopted by that Committee. Its members were dismayed that action had fallen short of what it should have been.

Resolution (a) of the Council was really divided into two parts, said Dr. Jones. The first part was concerned with the dangers of a Government monopoly in medical services being created and with the need to do everything possible to encourage private practice. Resolution (b) was concerned specifically with Independent Medical Services Ltd. (I.M.S.), of which he was the chairman. It must be recorded with regret that, though a number of Divisions did call meetings to publicize I.M.S., and though on some occasions the Council was represented by a speaker other than himself, nevertheless there were many meetings at which no member of Council was present.

It was also sad to recall, continued Dr. Jones, that, though I.M.S. was set up with the support of the Representative Body and the Council, he had never been able to find a single letter to the profession as a whole, other than those written by himself, asking the profession to give the financial support to I.M.S. which it needed if the B.M.A.'s policy in respect of private practice was to be implemented.

The CHAIRMAN intervened to say that Divisions had been asked to assist, and he wondered how many had responded.

Dr. JONES replied that approximately 40 Divisions had done so.

The CHAIRMAN said that that was 40 out of some 300 Divisions. Referring to the Private Practice Committee's recommendation on the Council's agenda, he pointed out that it urged "resolute and continuous action" by all concerned. He asked Dr. Jones what more the Council or anyone could do.

Dr. JONES replied that, though the Council had accepted that to ensure the success of I.M.S. a fund of not less than £200,000 was needed, there had never been one official letter of appeal from the Association to the membership. A phrase which had been used to describe the project was "Ivor Jones's private army," and that was how it had been viewed by too many, but it was doubtful whether it would have been viewed in that way had there been a letter from the Association in support of its declared policy. "All I am asking is that the Council should be consistent," said Dr. Jones. "It is pointless to enunciate a policy and then fail to do what is necessary to carry it out."

Reference Back Moved

Dr. R. L. LUFFINGHAM moved the reference back of the following paragraph in the Private Practice Committee's report which preceded its recommendation:

The policy was affirmed by the Representative Body in July 1967. The Committee is dissatisfied with the action taken up to date to encourage private practice and to assist Independent Medical Services Ltd. It deplores the lack of support for this aspect of the policy of the Association.

Dr. G. R. OUTWIN seconded the motion.

Dr. LUFFINGHAM said the reason he asked for the reference back of the paragraph was that it was a vote of censure on the Council. There must be a fair amount of feeling—quite rightly—in the Private Practice Committee that the success of I.M.S. had not been so great as had been hoped. His feeling was that the Committee was raging at the wrong body and had inserted what he regarded as offensive words into its report to the Council. It deplored the lack of support for what was the policy of the Association.

Dr. Jones had made it clear that it was the Council which was in the dock, but he had not much of a case. The Council traditionally laid down principles and it remitted to the Committees the day-to-day work. Council gave I.M.S. the go-ahead at the appropriate time, and it had a board of management. So far as Dr. Luffingham was aware there had never been an occasion when Dr. Jones had asked for anything of the Council on behalf of I.M.S. when the Council had not done what was asked of it. "I submit that, far from Council having to set the pace and tell us how I.M.S. should be publicized and how money should be raised, it is for the Private Practice Committee with the information it has from I.M.S. to come before this Council to recommend specific action."

The Private Practice Committee was disturbed at the lack of support for I.M.S., and in Dr. Luffingham's view it was that which had led to the intemperate language. "Many of us are disturbed about I.M.S. because it

has not fulfilled what was hoped," he added, "but we are prepared to look for more radical reasons why it has not been satisfactory." Dr. Luffingham said that his branch had recently commissioned a questionnaire to be sent to all its members asking what support there was not only for I.M.S. but for a return to private practice in general practice. It was thought that there would be little support for the restoration of private general practice, and if that was the case it would explain why only 40 divisions out of 300 had called a meeting about I.M.S. "I think it is time that the Private Practice Committee had a careful look at the whole concept of I.M.S. and decided whether in fact its original remit was the right one," Dr. Luffingham concluded.

Dr. OUTWIN said he took the gravest possible exception to criticisms of the Council by the Chairman of I.M.S. (Dr. Jones) in his role as Chairman of the Private Practice Committee. In Dr. Outwin's view the Council must review its support of I.M.S. in the light of its changing appearance.

Dr. C. M. SCOTT said the Council was witnessing a somewhat curious attack on I.M.S. He was not particularly interested in defending all the ramifications of I.M.S. Indeed, there were one or two aspects of it with which he would personally disagree. But I.M.S. was the only possible solution, which the Council had backed, for producing an alternative medical service. Dr. Scott said he was not at all convinced that the root cause of the trouble lay with the Representative Body or with the Council. He thought it lay in the medical profession generally. The lack of increase in private practice was more due to lack of interest by doctors than to lack of demand by the public. With one notable exception, there was not only a complete disinterest in private practice but almost a disinclination to see it return in any shape or form. Until the idea of private practice could be sold to the medical profession it would be impossible to persuade the public, though a number were asking for the return of private practice and were experiencing difficulty in finding a doctor to attend them privately.

Evangelical Mission

Dr. WALLACE said that Dr. Jones had pointed out that I.M.S. was not getting the support it required if it was to become a success. Dr. Jones had suggested something in the way of mounting "an evangelical mission," which would have the support of the Council, to make doctors realize that, though there might be no immediate gain in joining I.M.S., the ultimate gain was infinite. At the moment many doctors were wallowing in wealth when compared with the poverty of some doctors a few years ago, continued Dr. Wallace, but wallowing in comparative wealth had never been a good atmosphere in which to conduct a mission. He hoped the Council would not take umbrage at the paragraph in the Private Practice Committee report, and would not read into it things that were not there.

Dr. C. C. LUTTON said that I.M.S. had been supported fairly well, but not by the patients, and that surely was one of the main reasons why the results were disappointing. He suggested that I.M.S. should be considered rather like the Territorial Army and held in

reserve. Some day an alternative health service would be needed. The crisis had died away at the moment.

Dr. J. E. MILLER said there was an unfortunate tendency for the matter under discussion to be regarded as a private battle between Ivor Jones's private army and the Council. Dr. Miller asked the Council to realize that it was not a private controversy at all. It was a unanimous recommendation of the Private Practice Committee that reference to the lack of support for I.M.S. should be made in its report to the Council.

The Council should not allow the debate to blow the matter up out of all recognition. It should be kept in its proper perspective. There had been from the start an unfortunate feeling that I.M.S. did not have the whole-hearted support of the Association through the Council. He had been told on several occasions that there was lukewarm support from the Council for I.M.S. It was all very well to say that the root cause of the failure of I.M.S. to attract support appeared to be among doctors at the periphery. There had been lukewarm interest in many aspects of B.M.A. activity in the past on the part of doctors at the periphery. They were, however, subject to changes of mind provided they recognized that they were getting a lead from the top. It was a lead from the top that Dr. Miller said he pleaded for, and was the reason for the insertion of the paragraph in the Committee's report.

He was delighted to hear that Dr. Luffingham's Branch was interested enough to go to the expense of sending out a questionnaire to its members drawing their attention to I.M.S. and asking for their views on private practice. If more Branches and Divisions took similar action, and if members of the Council recognized the importance of I.M.S., even as an insurance for the future, perhaps more interest would be stimulated at the periphery.

Dr. Miller suggested that not only had there not been sufficient stimulus from members of the Council, but Divisional and Branch secretaries should have constantly been stimulating their members to take action in the matter. Whether the fact that only 40 Divisions had held meetings to discuss I.M.S. reflected lack of interest on the part of doctors at the periphery or reflected lack of activity on the part of members of Council and Divisional secretaries was for the Council to judge. But there could be no doubt in the mind of the Council that failure on the part of any section of the B.M.A. reflected failure on the part of the Association as a whole, and the Association in the future would be blamed by doctors at the periphery for not having taken a stronger line in stimulating further interest in I.M.S.

A motion that the question be now put, proposed by Dr. A. M. RANKIN and seconded by Mr. G. E. MOLONEY, was carried.

Dr. JONES, in reply, asked the Council to look again at the paragraph which it was being urged should be referred back. He quoted from it. The first sentence was "The policy was affirmed by the Representative Body in July 1967." There was no doubt about that. Policy had been enunciated fully at the Annual Representative Meeting in Bristol and had been approved by the Representative Body. "The Committee is dissatisfied with the action taken up to date to encourage private practice and to assist

Independent Medical Services Ltd." The Council, said Dr. Jones, now knew why the Private Practice Committee was dissatisfied with what had been done up to date to support that policy. "It [the Private Practice Committee] deplores the lack of support for this aspect of the policy of the Association." That, said Dr. Jones, was an expression of opinion on the part of the Committee.

In moving the reference back Dr. Luffingham had suggested that he (Dr. Jones) had been intemperate in submitting the report to the Council. Dr. Jones assured the Council that if it had listened to the debate in the Private Practice Committee it would think that he had been very temperate indeed in putting the Committee's recommendation to the Council.

Dr. LUFFINGHAM, in reply, said he hastened to point out that he had not attacked Dr. Jones personally. Secondly, he had suggested that it was the Private Practice Committee which had been intemperate and not Dr. Jones. He assured Dr. Scott that he was not against private practice. What he was unhappy about was that the product being offered was unacceptable to the customers—that was, the doctors. In Dr. Luffingham's view the Council was being censured, and Dr. Jones had not suggested that it was not a vote of censure.

The motion to refer back the paragraph was lost.

Committee's Recommendations

The CHAIRMAN then drew the Council's attention to the recommendation of the Private Practice Committee:

That the Council, recognizing that the policy of extending private practice and of giving all practicable support to Independent Medical Services Ltd. has been approved by the Representative Body, urges resolute and continuous action in this respect by all concerned.

Dr. RIDGE said he was unable to support the recommendation, because it was far too imprecise. For example, what was meant by "continuous action"? Did it mean that those concerned had to ensure the encouragement of I.M.S. all day and every day to the exclusion of everything else? Secondly, the implication of what was said in the presentation of the report was that "all concerned" included all members of Council. But if it was accepted that every member of Council had to take action on every policy decision of the Council then manifestly they were being asked to do something that was impossible. Therefore, why should a particular policy decision of the Council be singled out? If "all concerned" meant subscribers to I.M.S. that was a different matter, but it was not clear.

Dr. J. HENNEMAN said it was clear what the Private Practice Committee meant. It asked that the Council should do everything in its power to implement what was the policy of the Association. There were many ways in which the Council could do more along the lines outlined by Dr. Jones. One was to get the public interested in I.M.S. At the moment many doctors did not join I.M.S. because the public did not know about it until they were ill and visited the doctor's surgery and saw the notice about I.M.S.

Dr. WALLACE urged the Council not to read into the recommendation things which

were not there. "If we want to support the decisions of the Representative Body and Council let us adopt this recommendation," he said.

Dr. JONES said he had had to deal with hundreds of letters and phone calls from members of the public who wished to find a doctor who would provide services under the I.M.S. scheme but who had been unable to do so. "I cannot believe that such a situation would continue if all of us were doing all we could to promote a scheme which was twice supported and twice approved by the Representative Body," he concluded.

Dr. R. E. W. OLIVER said he thought that the character of I.M.S. had changed, and he asked Dr. Jones for an assurance that it had not changed since it was last discussed. Dr. JONES gave an assurance that the primary objects of I.M.S. remained what they had been at the outset—to further private practice in this country and to enable the profession and the community to participate in it.

The recommendation was adopted.

The CHAIRMAN said that both he and the Secretary were worried about the wording of the recommendation, because they did not know what the Private Practice Committee wanted them to do. He asked whether the Committee could submit a memorandum indicating exactly what it wanted done.

Dr. JONES replied that now that Council had adopted the recommendation his Committee would of course submit a memorandum setting out specifically what it wanted done.

It was agreed that any further action should await the Council's consideration of the memorandum.

The Committee's report was approved.

Occupational Health Committee

Dr. R. E. W. FISHER, chairman of the Occupational Health Committee, attended by invitation to present its report.

He referred to negotiations with the British Railways Board and the National Coal Board on the pay of medical officers employed by those boards, and he said that the Committee was pleased with the results.

Dr. J. M. DUNLOP asked why the claim in respect of British Railways was backdated to 1 July 1967, whereas the claim in respect of the National Coal Board was backdated to October 1966.

Dr. FISHER replied that the National Coal Board had been prepared to accept that there had been an existing commitment to review pay before the freeze started on 20 July. British Railways had not been prepared to accept that it had a commitment.

Dr. DUNLOP asked whether the claim to British Railways had been put in before the freeze started. Dr. FISHER said that the detailed claim was not put in to the Coal Board or the Railways Board before 20 July, but because the Committee had been in continuous negotiations with the National Coal Board the Board was prepared to accept that continuing discussion implied a commitment to review.

Asked whether doctors employed by British Railways were happy with the settlement, Dr. Fisher replied that naturally they would have liked more, but they were prepared to accept what was obtained.

The report was approved.

Committee on Medical Science, Education, and Research

Mr. A. LAWRENCE ABEL presented the report of the Committee.

He said the Committee would like the Council's advice on how the following recommendation in the Committee's report should be implemented: "That Council take whatever steps necessary to draw Resolution 461† to the attention of Parliament. In this connexion the matter might be ventilated through the Parliamentary and Scientific Committee, of which the Association has recently become a member."

Mr. Abel said that a working party had been set up to explore the pros and cons of the use of amphetamine drugs.

The CHAIRMAN said that he was a member of the Home Office Committee on Drug Dependence, and it was sympathetic towards the B.M.A. and had been most helpful and co-operative. He asked whether Resolution 461 should be sent to that Committee.

The Council agreed with the suggestion.

Dr. SKENE said that the Ministry of Health already had a draft memorandum which covered a good deal of the recommendation contained in Resolution 461. It had been seen by the Joint Consultants Committee.

The Council agreed to make a grant not exceeding £250 towards the cost of a half-day symposium on the subject of the structural design of operating-theatres, with specific reference to the control of infection. The symposium, which was to commemorate the Lister Centenary, would be held at B.M.A. House on 8 December in the afternoon.

The report of the Committee on Medical Science, Education, and Research was approved.

Central Ethical Committee

Dr. J. S. HAPPEL presented the report of the Central Ethical Committee on behalf of its chairman, Dr. W. Woolley.

He said that Dr. Woolley had been appointed Chairman of the Committee on the retirement of Dr. S. Noy Scott. The Committee had placed on record its warm appreciation of the outstanding manner in which Dr. Noy Scott had conducted the proceedings of the Committee for the past ten years.

The report of the Central Ethical Committee was approved, and the Council endorsed the expression of appreciation by the Committee of the work which Dr. Noy Scott had done during the years in which he had been its Chairman.

Welsh Committee

Dr. A. WESLEY HILL presented the report of the Welsh Committee in the absence of its chairman, Dr. Rowland J. Williams.

He reported that the Committee had completed its study of the second report of its Subcommittee on Area Health Boards, which had been drawn up in the light of the criticism received on the progress report of

1966. The second report was submitted to the Council with the recommendation that its circularization as a report of the Welsh Committee of the Association should be approved.

The Council expressed gratitude to the Welsh Committee for producing an excellent report, and it was agreed that it be referred to the Association's major standing committees for consideration and report at the meeting of the Council in January.

The report of the Welsh Committee was approved.

Journal Committee

The CHAIRMAN welcomed Sir Alan Moncrieff, the newly elected Chairman of the

Journal Committee (*Supplement*, 21 October, p. 23).

Sir ALAN MONCRIEFF, in presenting the Committee's report, referred to the retirement from the chair and from the Committee of Dr. J. G. M. Hamilton, and said that he would be very much missed.

Sir Alan Moncrieff called attention to the Committee's proposal that within the next two years the printing of the *B.M.J.* should be changed from flat-bed letterpress to web-offset. With new methods of printing it should be possible to speed up the process and to ensure that every member of the Association received his *B.M.J.* by the Saturday morning.

The report of the Committee was approved

Public Health Committee

Dr. C. METCALFE BROWN presented the report of the Public Health Committee.

Salary Claim

Dr. Metcalfe Brown reported that since the sanctions on local authority public health appointments were introduced in May two emergency meetings of the Committee had been held to discuss proposals from the Management Side of Committee C in response to the salary claim on behalf of public health medical officers.

A further meeting of the Committee had been held on 11 October to discuss the latest offer. Though it contained the elements of a possible settlement, the Committee had been unable to accept certain of the conditions proposed by the Management Side.

The Council heard *in camera* a report from Dr. Metcalfe Brown on the nature of the Management Side's offer.

Appointment in Surrey

Dr. Metcalfe Brown said that the post of county medical officer of health of Surrey had been advertised and filled during the summer. After a meeting called by the British Medical Guild of all doctors in contract with Surrey County Council representations had been made to the chairman of the County Council about the action of his authority in filling the vacancy during the period when the British Medical Guild had recommended all doctors not to apply for public health medical appointments. It was known that a number of distinguished medical officers of health had abstained from applying for the post as a result of the Guild's recommendation, and it was believed that no county medical officer of health had applied.

A deputation had seen the chairman of the Surrey County Council and had put the profession's case. It was pointed out that the number of applicants must have been seriously reduced by the operation of the Guild's recommendation, and that the action of the authority in filling the appointment would have the most serious consequences on the local health authority services in the country. [A report of a British Medical Guild meeting on 26 October appears at p. 41.]

County Borough of Tees-side

Dr. METCALFE BROWN reported that an advertisement published in *The Medical Officer* and in the *Lancet* for a medical officer of health for the newly created County Borough of Tees-side in September 1967 contained the sentence, "This advertisement is made with the agreement of Committee C of the Medical and Dental Council." The Public Health Committee considered the statement to be misleading, and a notice to that effect was published in the *British Medical Journal* and in *The Medical Officer* of 23 September.

Dr. G. N. MARSH said that when the post was advertised the local public health medical officers who were in order in applying for it wrote to the Association to see whether they should do so. Other medical officers of health withdrew their applications when they heard of the B.M.A.'s embargo. Nevertheless, the post had now been filled.

Expectation of Life

Dr. R. P. HENDRY protested about the way in which the Public Health Committee was handling the question of career earnings. He referred to a statement in the Committee's report that consideration had been given to a resolution of the A.R.M. 1966 requesting that the Council should publish the average expectation of life of the various branches of the medical profession and compare and contrast those with those of certain other professions mentioned in the Report of the Royal Commission on Doctors' and Dentists' Remuneration. "The Committee," stated its report, "is of the opinion that no useful purpose would be served by attempting to compare the average expectation of life in the various branches of medicine with that of other professions."

Dr. Hendry suggested that the A.R.M. resolution was being handled in a slipshod manner. Indeed, it had been quietly sat upon for fifteen months, and was then grossly misquoted and rejected in an unconstitutional way. The A.R.M. resolution was a straightforward instruction to the Council that it should publish the average expectation of life of those in the various branches of the medical profession and compare and contrast them with those of the professions mentioned in the Royal Commission's report, thus finally to

† Resolution 461 of the A.R.M. 1967 reads as follows: "(i) That this Meeting recommends that when a patient has completed treatment for drug addiction there should be adequate provision for his rehabilitation and follow-up on a long-term basis, such rehabilitation should be directed by a person with proper skill and experience in this field and (ii) that the Government be urged to implement all the other recommendations of the Brain Committee report of 31 July 1965."

explode the myth of career earnings. Dr. Hendry submitted that statistics were needed and not opinions. He accordingly moved that the part of the Public Health Committee's report dealing with career earnings should be referred back. • Dr. OUTWIN seconded the motion.

Dr. METCALFE BROWN said he would have appreciated some notice of the charge which Dr. Hendry had made. He would be willing to look at the point if he could be furnished with the information. What the resolution asked for was a big research job which might or might not be worth while. However, he was certain that it would cost the Association a great deal of money.

The motion was carried, and the Public Health Committee's report, duly amended, approved.

General Purposes Committee

The CHAIRMAN presented the report of the General Purposes Committee.

I.M.S. Discount Scheme

Dr. OUTWIN moved the following motion: "That this Council is opposed to the assistance of Independent Medical Services Ltd. by the B.M.A. in respect of aspects of the trade discount scheme activities which overlap existing activities for which Association support is already policy, and thereby rejects the section of the Private Practice Committee's report dealing with the discount scheme."

Dr. DOWLER seconded the motion.

Dr. OUTWIN said he wanted to make it clear at the outset that the motion was not intended as an attack upon I.M.S. or a personal attack on any member of its board of management, or on Dr. Jones in particular. He wanted to point out that the Association's business sense would seem to be in grave doubt if the proposal outlined in the General Purposes Committee's report was adopted.

It was apparent that the trade discount scheme had territorial ambitions which knew no boundaries. It was the avowed intention of I.M.S. to spread its ubiquitous net over insurance, travel, and wines and spirits among other things. That raised some important issues. The Association had its own Hastings Wine Club. Members might or might not regard the club as a successful project in what was a highly competitive field, but it was one which was launched some years ago with a fanfare of Association trumpets, and in the minds of all members the Hastings Wine Club was part of the B.M.A. and it should not be lightly jeopardized.

So far as the Medical Insurance Agency (M.I.A.) was concerned, the B.M.A. had no direct control over M.I.A., but for some 60 years there had been a close connexion between the B.M.A. and the M.I.A. and the profits of the M.I.A. went to medical charities. That relationship with the M.I.A. must be regarded as an Association asset.

I.M.S. was a commercial organization over which the Association had no control. According to the report of the General Purposes Committee, M.I.A. would be willing to co-operate with I.M.S. "on the assumption that its scheme had the Association's approval." M.I.A. was "over a barrel,"

because it was in no position to express opposition to anything which was Association policy. Nevertheless, if I.M.S. appeared to be a competitor in the field of insurance relationships with M.I.A. would doubtless suffer. Dr. Outwin asked the Council seriously to consider whether it would be wise for the Association to hand over its assets in the form of the Hastings Wine Club and help to medical charities to an organization over which it had no control whatever.

B.M.A. Organization

Dr. DOWLER, speaking as chairman of the Hastings Wine Club, said that it was founded 8 to 9 years ago, and it could be said to have been successful. It had some 5,500 members, and it was under the control of a committee which was appointed and controlled by the Organization Committee. It was an Association organization completely.

Some time ago Dr. Jones had arranged for the manager of the I.M.S. trading scheme to see the secretary of the Hastings Wine Club to discuss the question of selling wines and spirits. The question was whether the new I.M.S. service and the Hastings Wine Club could co-operate. It was explained that there was no possible way in which the I.M.S. service and the Club could co-operate. It was further explained that the Club was run entirely by the Association, and it was thought that the I.M.S. service should desist from offering wines and spirits. Dr. Jones had agreed, and it was rather surprising to read in the report of the General Purposes Committee that wines and spirits should be sold through the facilities division of I.M.S.

Dr. Dowler suggested it was wrong in principle for a service sponsored by the B.M.A. to set up in direct competition with a service already given by the B.M.A. I.M.S. was independent and could do what it liked, but the Association had sponsored it. It was an irrational and undesirable situation.

Dr. LUTTON said that the mail order business was always a dangerous one. Discount trading would always have its problems. When he learnt of the facilities being offered by I.M.S. he put the matter to his three partners, and all of them agreed that if I.M.S. went into the wine and spirit business they would ask for their £10 subscription back. They pointed out that they were not in medicine to put up a shop in the Association. Furthermore, if money were lost who would stand that loss?

Dr. J. S. ROSS said that in his view there was much to be said for the scheme in attracting membership to the Association. At the same time, however, he agreed that it was unwise, unfair, and unkind to tread on the feet of the M.I.A., who had been good friends of the Association for many years. Whatever was done it was bound to jeopardize friends in the Medical Insurance Agency. The Hastings Wine Club was part of the Association, and it would be ridiculous to put up a rival organization within the aegis of the B.M.A.

Dr. J. COTTRELL said he thought that the introduction of the proposed scheme would probably help to undermine the good image which the Association had always endeavoured to put before the public.

Dr. HAPPEL thought that everyone was being a little hard on Dr. Jones. After all, the Council was under an instruction to pro-

vide such a service, which was now possible through I.M.S. When members wrote in and asked for goods on discount there was no need to draw any distinction between electrical goods and wines and spirits.

Interests of Profession

Dr. D. J. PEREIRA GRAY said that one of the objects in the Memorandum and Articles of Association of the B.M.A. was to promote the interests of the profession, and he submitted that the proposed scheme did promote those interests. Speaking for younger doctors, a pound saved was more valuable than a pound earned, because tax was not paid on it. As a result of the trade discount scheme new money would be brought into I.M.S. at no cost to the Association, and it would be an attraction to membership of the B.M.A.

Dr. JONES, in reply, outlined the history of the I.M.S. discount trading scheme, which had become policy of the Association in July. Far from rendering any disservice to M.I.A., far from depriving it of any custom, the activities of I.M.S. were already channelling to M.I.A. custom which it might not otherwise have received. Dr. Jones said he had letters from the M.I.A. welcoming the arrangements which had been made between the two bodies. No commission on insurance business was taken by I.M.S. except in respect of arrangements which were sometimes made in connexion with hire purchase. In that case he did ask for a modest commission on the transaction to meet the costs of what was being done. It was a service to M.I.A. that in respect of all motor cars obtained on hire purchase through the I.M.S. scheme at least the purchasers' attention was directed to the facilities which the M.I.A. offered. There was already evidence of an increased volume of business going to M.I.A.

Among the things which Dr. Jones's manager reported to him as part of his general remit to make the best arrangements he could were arrangements in respect of wine and spirits. Dr. Jones said he was aware of the Hastings Wine Club. He had found that it was bound hand and foot to one particular firm. He was further amazed to find on a preliminary survey that it was possible for the I.M.S. discount scheme to arrange for wine and spirits to be available to doctors on better terms than the Hastings Wine Club could offer.

However, I.M.S. was still anxious to help the Hastings Wine Club to the maximum possible extent, and his manager had met Dr. Dowler and Dr. Potter. The manager had reported back that there was no prospect of agreement, because the Club was bound hand and foot to one particular firm. Dr. Jones said he had made it clear to the secretary of the Wine Club that I.M.S. would be prepared to supply it with wines and spirits which the Club could disburse if it wanted to on better terms than were currently available, "but they did not want that."

Go Ahead

Dr. Jones said he had agreed to defer decision on all the outstanding matters until the General Purposes Committee had considered them and to abide by whatever decision it reached. It had, however, been necessary to indicate at the time that once

the Committee's decision had been reached I.M.S. would go ahead with its discount scheme. The General Purposes Committee had debated all the matters and had voted in favour of the I.M.S. discount scheme. Even then, so far as wines and spirits were concerned, Dr. Jones said he made a further endeavour to reach agreement with the Hastings Wine Club, but it had not proved possible. Dr. Jones said he had arranged, despite the vote of the General Purposes Committee, not to issue a catalogue of wines and spirits to anyone who did not specifically inquire whether he could be provided with wines and spirits.

Dr. Jones said he was somewhat puzzled by the motion, because he did not know what Dr. Outwin thought I.M.S. had been receiving in the way of financial support from the Association. I.M.S. had paid for the letter and application form that went out with "B.M.A. News," and it had paid for its advertisements in the *B.M.J.* He was therefore at a loss to understand what Dr. Outwin thought should be withdrawn from I.M.S. and which he believed, erroneously, that I.M.S. had received.

Dr. OUTWIN said he had not suggested that I.M.S. was proposing to do anything that would in any way jeopardize M.I.A. He had merely pointed out that I.M.S. was an organization over which the B.M.A. had no control. He agreed that certain members of Council were on the board of management of I.M.S., but that did not mean that the Association had ultimate control over the organization. However well intentioned I.M.S. might be now there could be no guarantee of the ultimate outcome of the relationship.

In the case of the Hastings Wine Club, the chairman and secretary of the club found I.M.S. an unacceptable bed-fellow, so the two bodies were in open competition. Why was Dr. Jones's organization so altruistic in channelling so much new custom into M.I.A. and taking no profit? Obviously it would not lose anything if the motion were carried by Council.

The motion was lost.

Different Policy

Dr. RIDGE then read a letter from a Division expressing disquiet that the I.M.S. discount service was not now in the form approved by the Representative Body.

Dr. JONES said that Dr. Ridge had asked for an explanation of the change from a policy of charging one or two guineas as a subscription to the I.M.S. discount service to one of making it freely available to members of the B.M.A. and to I.M.S. subscribers, whether or not they were members of the Association, and also to members of the British Medical Students Association.

Dr. Jones said that when the original project was placed before the Council in 1966 it had been a confidential document. He was well aware then that anything being offered would very likely be copied, if the opportunity presented itself, by certain other organizations. Council might like to consider whether in fact there was any leak of the intentions of the Association. The fact remained that the position had changed very much in that by the time the Representative Body had approved the I.M.S. discount scheme there was in existence, available without subscrip-

tion to doctors, whether members of the B.M.A. or not, a discount trading service of a kind. It had been necessary therefore to consider whether I.M.S. should proceed along the lines originally intended. He discussed the matter with his Committee and with the Chairman of Council, the Secretary, and others, and they agreed that if it were possible I.M.S. should offer the service to members without any additional subscriptions.

Dr. Jones said he had disclosed all the facts to the General Purposes Committee. He had not taken any final decision until he had known the views of that Committee, and there had not been one dissentient.

Dr. RIDGE said he would be satisfied if the explanation for the change in policy on subscriptions to the I.M.S. discount service were given to the Representative Body in the Annual Report of Council for 1967-8. It would then be for the Representative Body to decide whether it accepted the change that had been made in its policy without it being consulted.

Dr. HAPPEL suggested that, in view of what Dr. Jones had told the Council, the General Purposes Committee should again consider whether it was best for the Hastings Wine Club to remain restricted to one supplier when there were better terms available through the trade.

Dr. DOWLER pointed out that the Hastings Wine Club was not set up merely for the purpose of buying wines and spirits cheaply. It was also set up to help doctors to become interested in and learn about wines. The club organized tours of wine-growing areas and suchlike.

The report of the General Purposes Committee was approved.

B.M.A. and Magistrates

Dr. G. S. R. LITTLE presented the report of the Joint Committee of the B.M.A. and Magistrates' Association.

The CHAIRMAN congratulated the Adoption Subcommittee of the Joint Committee on the Memorandum on Adoption that was before the Council for approval.

The Council adopted a recommendation that, subject to its approval by the Council of the Magistrates' Association, the memorandum should be submitted to the Home Office and any other appropriate bodies.

The Council also adopted a further recommendation that the Home Office be urged to consider: (a) extending the facilities provided for the treatment of drunken offenders to drug offenders; (b) making disorderly behaviour while under the influence of drugs an offence, so that opportunities would become available to the Courts to order treatment; (c) empowering the Courts to confiscate all drugs and addicts' gear in the possession of persons convicted of drug offences; (d) better priority for outpatient psychiatric reports.

The report of the Joint Committee was approved.

Breathalyser Tests

Dr. HAPPEL referred to the Breathalyser test, and asked Council to support all efforts to standardize unofficial apparatus and to encourage their use in every way possible, because they were helpful to the public. He further pointed out that nothing had been done to try to alter the whole pattern of social drinking in private houses. He understood that in Canada it was customary for the host to present his guest with a bottle and a glass and ask him to help himself. That might be usefully adopted in this country with a special measure.

Council agreed to submit the points raised by Dr. Happel to the B.M.A.'s Expert Committee.

Other Committees

The reports of the following Committees were approved without discussion: Annual Meetings Committee, Scottish Council, Full-time Medical Teachers and Research Workers' Committee, Committee on Overseas Affairs, Finance Committee, Armed Forces Committee, Film Committee, G.M.S. Committee, and Family Doctor Committee.

The meeting terminated at 6.30 p.m.

H.M. Forces

ROYAL NAVY

ROYAL NAVAL RESERVE

Surgeon Commander H. R. Gray, V.R.D., has been placed on the Retired List.
Surgeon Lieutenant R. C. Clark to be Surgeon Lieutenant-Commander.

ROYAL ARMY MEDICAL CORPS

Major J. C. Wilson to be Lieutenant-Colonel.
Major J. H. Taylor has resigned his commission.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel S. Ward, having attained the age limit, ceases to belong to the Reserve of Officers.

Major (Honorary Colonel) W. H. Valentine, O.B.E., E.R.D., having exceeded the age limit, ceases to belong to the Reserve of Officers, and has been restored to the rank of Colonel.

Major W. N. L. Haynes, having exceeded the age limit, ceases to belong to the Reserve of Officers.

Major E. J. Ewell, O.B.E., T.D., from T.A., to be Major.

Major R. L. Jillett, T.D., has relinquished his commission on appointment to a commission in the Royal Auxiliary Air Force with the rank of Squadron Leader.

TERRITORIAL AND ARMY VOLUNTEER RESERVE

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel A. A. Shivas, T.D., has reverted to the rank of Major.

Captain (Acting Major) J. Grier, from T.A., to be Captain, retaining the acting rank of Major. (Substituted for the notification in a *Supplement* to the *London Gazette* dated 4 April 1967.)

Captain I. D. Walters to be Major.

ROYAL AIR FORCE

Squadron Leader E. D. Colterjohn has retired at his own request.

Flight Lieutenant D. J. Clarke to be Squadron Leader.

ROYAL AIR FORCE RESERVE OF OFFICERS

Flight Lieutenants I. W. Geere and D. C. Prior to be Squadron Leaders.

Central Committee for Hospital Medical Services

The existing Interim Negotiating Subcommittee for hospital medical staff—the “Committee of Fifteen” appointed early in the year—is to remain in office to finish the preparation of evidence for the Review Body. The Negotiating Subcommittee for 1967–8 will be elected in December. Three out of the nine members elected to the Executive Subcommittee of twelve were representatives of hospital junior staff. The three ex officio members are the chairman and the two deputy chairmen. The C.C.H.M.S. did not take exception to the Sainsbury Committee’s report in general but emphasized the importance of the proposed Medicines Commission being independent. The Committee thought ambulances going to accidents should carry pain-relieving drugs for the use of any doctor who might be on the scene but unequipped. The value to the B.M.A. of the statistical group set up jointly by the profession and the Ministry of Health was explained by the Secretary. The Committee dealt with a number of resolutions referred to the Council from the Annual Representative Meeting 1967 and also A.R.M. motions which had not been debated by the A.R.M. and had been referred en bloc to the Council. A subcommittee is to be appointed to study the question of the medical staffing of the casualty service in hospitals.

A meeting of the Central Committee for Hospital Medical Services was held on 20 and 21 October. Mr. H. H. LANGSTON was in the chair.

Negotiating Subcommittee

The Committee considered the appointment of the Negotiating Subcommittee.

The CHAIRMAN reminded the meeting that an interim negotiating subcommittee of 15 members (the “Committee of 15”) had been set up in the middle of the last session. It had met three times, and it had been almost entirely occupied in preparing evidence for the Review Body. He thought it would be a great mistake to change the subcommittee’s membership at this stage: it should be allowed to finish its task. He suggested that the election of the Negotiating Subcommittee for the session 1967–8 should be postponed until early next year.

Dr. E. A. HARVEY-SMITH, chairman of the Hospital Junior Staffs Group Council, agreed that the existing membership should remain for the present, but he hoped it would be reviewed at the meeting of the Central Committee for Hospital Medical Services (C.C.H.M.S.) in December.

The Committee agreed with Dr. Harvey-Smith’s proposal.

Executive Subcommittee

The Committee considered the appointment of its Executive Subcommittee, which had consisted of the chairman, the two deputy chairmen, two members nominated by the C.C. and S. Committee (Scotland), one member nominated by the Hospital Junior Staffs Group Executive Committee, and six members elected by ballot.

Dr. HARVEY-SMITH proposed that the Executive Subcommittee should be increased by two members, and that three places on it should be reserved for members of the hospital junior staff.

Dr. H. GLYN JONES was disturbed that the Executive should be split into groups. Dr. N. STRANG (chairman of the Senior Hospital Medical Officers Group Council) proposed that there should be a place on the Executive reserved for S.H.M.O.s. Dr. H. L. LEAMING hoped that at least seven places would be reserved for non-teaching staff.

The CHAIRMAN said he hoped he would not have to put these proposals as formal motions. The Committee could nominate whom it wished. It was unfortunate that

there should be talk about teachers and non-teachers when the regional peripheral hospitals were all trying to do more and more teaching.

Mr. H. A. KIDD said that the regional hospitals were badly represented, and they had got a raw deal in the last review. There was still a division between the teaching and the non-teaching hospitals. The teaching hospitals took what they could out of the cake and what was left had to be shared out among the non-teaching hospitals. Every committee was heavily weighted in favour of the teaching hospitals’ views. It was time the consultants in the regions were better represented.

Dr. GLYN JONES pointed out that if the Central Committee was heavily weighted in favour of teaching staff then that tendency was bound to be spread through its subcommittees. Mr. J. R. BLACKBURN said that, as a non-teaching hospital consultant, he would be sorry to see the composition of the Executive tied to a particular proportional representation. It was up to the Committee to choose the best men.

The CHAIRMAN believed that any sort of division would be unhelpful. He suggested that members of the Executive should be elected as individuals and not as members of particular groups.

Dr. R. M. MAYON-WHITE proposed that the Hospital Junior Staffs Group should nominate three members, but that it would be still open to members of the C.C.H.M.S. to propose other names. When it came to the vote the top six of the senior members nominated would be elected and the top three of the juniors. Dr. HARVEY-SMITH agreed that the H.J.S. Group should nominate three members, but others were at liberty to put forward other names.

The Committee agreed to that proposal.

The following were elected: Mr. J. R. Blackburne, Mr. R. Myles Gibson, Dr. R. M. Mayon-White, Professor Ian Rennie, Dr. A. Skene, and Dr. G. E. Owen Williams (representing senior hospital staff), and Dr. D. Guttman, Dr. E. A. Harvey-Smith, and Dr. W. P. U. Kennedy (representing hospital junior staff).

Sainsbury Committee

Dr. A. SKENE reported to the Committee on the *Report of the Committee of Enquiry into the Relationship of the Pharmaceutical Industry with the National Health Service, 1965–7* (the Sainsbury Committee).

He said that the B.M.A. had submitted evidence to the Sainsbury Committee. There

had been a fear that the Committee might be prejudiced in favour of the nationalization of the pharmaceutical industry. These fears had been allayed by the committee’s specific statement that it did not recommend nationalization.

The first two-thirds of the report dealt with marketing procedures, advertising, and the profitability of the industry. Dr. Skene thought there was nothing in the recommendations which called for any action on the part of the medical profession at the present time. The Association of the British Pharmaceutical Industry was well able to speak for itself. Dr. Skene said that the part of the report which concerned the medical profession was the proposal for a Medicines Commission. The Sainsbury Committee considered that the Medicines Commission should have an independent constitution and should be plainly seen to be independent. It would have certain functions with regard to licensing, and it would also deal with standards of advertising and keep watch on the accuracy of claims. After outlining some of the other proposed functions of the Medicines Commission Dr. Skene concluded that there was no immediate danger to the freedom of practice of doctors, particularly in general practice, or any likelihood of limitations being placed on the industry which would diminish its research potential. He recommended that the C.C.H.M.S. should inform the Joint Consultants Committee that it did not disagree with the findings of the Sainsbury Committee, and that it supported the recommendation for an independent Medicines Commission, with the proviso that the matter should be kept under observation.

Dr. OWEN WILLIAMS said that the view of the B.M.A. was that the Medicines Commission should be completely independent, and that it should be the authority issuing and revoking the licences. The Ministry was the major, although not the exclusive, customer of the pharmaceutical industry. That was one of the reasons why the membership of the Commission should preferably be appointed by the various interested bodies.

Clinical Trials

Dr. R. MAGGS commented on the paragraph in the Sainsbury Report about clinical trials, in which it was recommended that in addition to satisfying the requirements of safety a new pharmaceutical product should, before being granted a licence, be shown in evidence produced to the Medicines Commission to have the efficacy claimed for it by the manufacturer. The evidence would in

most cases be expected to be in the form of reports of approved clinical trials. Dr. Maggs wondered what kind of "approval" was meant. The Committee did not seem to have made any recommendation that could help doctors to check more easily the basis upon which manufacturers made their claims. So often postal advertising material was full of names and references which doctors did not have time to check.

Dr. SKENE said that there was a limit to what an advertisement could carry, but the Sainsbury Committee had stressed the desirability of advertisements giving references to valid research. The Sainsbury Committee was concerned about the standard of clinical trials. They would need to be supervised.

Dr. D. P. STEVENSON, Secretary, pointed out that the Government's White Paper on forthcoming legislation on the safety, quality, and description of drugs and medicines

(*B.M.J.*, 16 September, p. 734) had stated that the appointments to the Medicines Commission would be made by the Minister of Health. The Sainsbury Report had stated that the Medicines Commission should be plainly seen to be independent. Had the Government produced its White Paper knowing what the recommendations of the Sainsbury Committee would be, or was it just coincidence? The B.M.A., he thought, should align itself with the clear recommendation in paragraph 335 of the Sainsbury Committee's report that the Medicines Commission should have an independent constitution and should be plainly seen to be independent.

The Committee, while finding the Sainsbury Report generally acceptable, and emphasizing strongly the importance of paragraph 335, considered that the matter should be kept under close review.

Ambulance Training and Equipment

The Committee considered Part II of the report of the Working Party on Ambulance Training and Equipment, set up in 1963 by the Minister of Health and the Secretary of State for Scotland. The Ministry of Health had asked for the Committee's comments on (1) the suggested role of the Central Ambulance Services Council in relation to equipment (including vehicles); (2) the standardization of equipment; (3) the interchange of equipment (for example, blankets) between hospitals and visiting ambulance vehicles; (4) the carriage and use of pain-relieving drugs and surgical instruments; and (5) the provision of clothing against radiation hazards.

Mr. WALPOLE S. LEWIN, a member of the working party, said that ambulances tended to be thought of in terms of their use in cases of accidents. Only 5% of those carried in ambulances were accident cases. It was for that reason that the working party had advised that there should not be separate training courses for accident work as distinct from the other duties of ambulance men, and that there should be one training programme for everyone. Similarly, the working party had set out what it believed to be reasonable equipment for all ambulances and had stated what should be available at ambulance stations for major accidents, and that it should be able to be got to the scene of an accident within half an hour. He did not think any comment could be made on the suggested role of the Central Ambulance Services Council until there was a central administrative body which would do for the ambulance service what had been done for the nursing services.

Standardization of equipment was important. Some things such as blankets were interchangeable, and there should be no need for ambulance men to take patients off stretchers in order to get their equipment back. Every ambulance should be equipped with oxygen and with suction apparatus.

Drugs and Instruments

The questions of the carriage and use of pain-relieving drugs and surgical instruments

had caused the working party more difficulty than any others. There were about six ambulance authorities whose vehicles carried morphine, and they all reported that it was rarely used. Mr. Walpole Lewin excluded from that special aspects of ambulance work such as that carried out by mountain- and sea-rescue parties. They carried pain-relieving drugs. But the majority of the medical advice on the working party had been that the risk of giving these drugs in circumstances when they would do more harm than good was greater than the benefit which undoubtedly resulted for the few. Two members of the working party had thought that pain-relieving drugs should be carried in ambulances, and they signed a minority report to that effect. In the final report it was recommended that at present such drugs should not be carried as a general routine, although certain circumstances when they should be carried were suggested. It was not thought that the provision of clothing against radiation hazards was necessary. Every ambulance depot had equipment which could be sent for in special circumstances.

The CHAIRMAN said that the Ministry of Health had asked all regional hospital boards for their comments on the minority report of the working party. There was some opinion in favour of pain-relieving drugs being carried, and to that had been tied the suggestion that ambulance men should have some training in hospitals to gain experience in using the drugs.

Mr. WALPOLE LEWIN, in reply to a question by Dr. J. D. Whiteside, said that when he had mentioned ambulances carrying oxygen he had been referring to ambulances used for accidents.

Mr. R. MYLES GIBSON thought that carrying pain-relieving drugs in ambulances should be given a trial in one or two areas, and the result should be reported on after two to three years.

The Committee agreed to recommend that that should be done.

Dr. GLYN JONES proposed that it should be recommended that ambulances should carry pain-relieving drugs only for the use of a doctor who might come upon the scene of an accident unequipped to deal with it.

Dr. Glyn Jones's proposal was carried by 21 votes to 20.

Ballot on Distinction Awards

The CHAIRMAN reported that on the instructions of a resolution of the Annual Representative Meeting 1966 a postal ballot had been undertaken of all senior hospital medical staff and senior registrars to ascertain their views on distinction awards. The results (*Supplement*, 21 October, p. 22) had indicated that there was support for the continuance of the awards but that some doctors wished to see certain changes. However, a substantial number made no comment at all, and there was no one subject other than secrecy that seemed to worry many doctors. He suggested that a copy of the report be sent to the Council, to the Joint Consultants Committee, and to the chairman of the Advisory Committee on Distinction Awards, Lord Platt.

Dr. S. J. HADFIELD, Scottish Secretary, who prepared the report on the ballot, said that some of the comments made, though striking, were made by only a few, and they might not therefore represent a wide section of opinion. Even those who commented on secrecy represented only 21.7% of the total returns.

Report on Negotiations

The CHAIRMAN reported that the Interim Negotiating Subcommittee had met twice since the last meeting of the parent committee. Both meetings had been mainly devoted to the preparation of evidence for the Review Body, which was now in the hands of the legal advisers. Negotiations between representatives of the Negotiating Subcommittee and of the Health Departments on the revision of Categories I and II of the Schedule to paragraph 167 of the Terms and Conditions of Service of Hospital Medical and Dental Staff were progressing satisfactorily.*

The Subcommittee was pressing the Ministry of Health on the payment of removal expenses of doctors moving from Northern Ireland to Britain. The Northern Ireland Government had agreed to pay removal expenses for doctors moving to Northern Ireland, but so far the Ministry of Health had been unwilling to make a reciprocal arrangement.

Mr. H. M. BENNETT, Northern Ireland, pointed out that the British Minister of Health did not recognize for seniority the years a young man might have spent as a registrar in Northern Ireland. This attitude might have had some validity some years ago, when the situation was different in Northern Ireland from Britain and a registrar became a senior registrar on getting certain qualifications, but now the system was the same in both countries.

The CHAIRMAN reported that the Negotiating Subcommittee had noted the following resolution of the Hospital Junior Staff Group Council: "That in future the Hospital Junior Staffs Group Council shall, when seeking evidence for the Review Body, brief the appropriate experts about the facts and figures to be discovered, so that these experts

* Paragraph 167 of the Terms of Service defines what work comes within the scope of the services provided under the N.H.S. and what does not.

may advise and devise the best means of discovering those facts."

Dr. S. CAMPBELL SMITH, a member of the H.J.S. Group Council, explained that it wanted to get independent evidence and not rely on Ministry sources, which might be accurate, but which were not always complete.

Dr. D. G. FAGAN, also a member of the H.J.S. Group Council, said that the intention was to find out what figures were needed and then to follow them through for perhaps five to ten years. At present figures were collected and then the experts gave their opinion on them. That was the wrong way round. The experts should decide what figures were needed, and then they should be collected and kept constantly up to date.

Statistical Information

Dr. STEVENSON said that for the B.M.A. to set up a department of statistics would require a large staff. The main source of any Association's statistical information must inevitably be Governmental. The Government could go direct to statutory authorities and require them to provide information. The Association could only make requests. A busy regional hospital board would be unlikely to provide the Association with statistics which could compete with the Government's. Therefore a year ago, by arrangement with the Ministry of Health, the B.M.A. agreed to take part in the joint statistical group. This group was never involved in policy. Its chairman was a statistician, and the Ministry of Health's representatives on it were the statisticians in the Department. On the Association side there were Sir Roy Allen, accountants, and economists. The result was that it got up-to-date and authoritative statistics. Another advantage was that such agreed statistics were not likely to be disputed by the Review Body. This was important, because in the past each side had put figures in evidence to the Review Body. The area of disagreement was now much narrower, and on matters such as emigration, work load, the number of doctors looking for jobs in general practice, and the number of vacancies the B.M.A. now had as much evidence as it was possible to obtain.

Dr. HARVEY-SMITH said that the negotiators did not have detailed figures of work load, though they might have global figures.

Dr. E. GREY-TURNER, Deputy Secretary, said he had been disappointed at what little help had been obtained from the profession itself. On three occasions he had written to regional consultants and specialists committees asking for material for evidence to the Review Body. There were 21 regional committees, and on the first occasion there was only one reply. On reminders being sent out he had received about 20 extremely good accounts from individual members of the position in particular units.

Consultant Staffing

The Committee considered the following resolution of the H.J.S. Group Council: "That the Group Council is of the opinion that, in order to make a thorough assessment of the ideal number of consultant posts in each specialty, the specialist groups of the B.M.A. should each determine a suitable and ideal work load (in all its aspects) for a consultant in their specialty."

Dr. HARVEY-SMITH said that consultant establishments should be based on objective studies independent of local vested interest and independent of what a particular regional hospital board might think. An establishment should be based on the work to be done in a particular hospital. The H.J.S. Group Council thought that the right way would be for the specialist groups to study the work load that they considered was right for a typical consultant to carry.

Dr. GREY-TURNER said that the profession had always been hostile to a time-and-motion study. It could be done on a time basis, but most people felt it was useless to establish criteria for highly specialized work, because time schedules did not measure the quality of the work or the weight of responsibility.

A decision on the matter was deferred to a subsequent meeting.

Mileage Allowance

The Committee considered a resolution from the H.J.S. Group Council asking for the support of the C.C.H.M.S. in bringing pressure to bear on the Ministry of Health by ceasing to use their private cars for a limited period in certain selected hospital groups.

The Committee rejected the resolution.

Resolutions of the A.R.M.

At the resumption of the meeting of the Central Committee for Hospital Medical Services on 21 October a number of resolutions of the Annual Representative Meeting 1967 which had been referred to the Committee were considered, together with a number of motions which, owing to lack of time, had not been debated by the Representative Body but had been referred en bloc to the Council. Representatives of the Divisions putting forward motions, or amendments to them, had been invited to attend the C.C.H.M.S. meeting so that they might have an opportunity of speaking to the motions.

Medical Services in Developing Areas

The Committee considered a resolution by Worcester and Bromsgrove: "That this Representative Body urges the Ministry of Health and its regional hospital boards to take note of proposals in certain areas to increase population densities, by redistribution, redevelopment, or formation of new towns, and to provide in good time appropriate hospital services for these areas."

Mr. F. S. A. DORAN, speaking to it, said that Birmingham intended to transfer 52,500 of its surplus population to Bromsgrove in about three years' time. Bromsgrove at present contained 43,990 people, so that the overspill would more than double its size to 96,490. The Bromsgrove General Hospital consisted of hatted units which had been scheduled to be demolished and rebuilt in 1960. Its total waiting list had risen in the last five years from 670 to 981, or by 47%. Increasing at that rate, the waiting list would have reached 1,229 by the time the first new house was occupied. There was no question of a new hospital being built at Bromsgrove, and even if there was there would be no nurses to staff it.

Hospital Pharmacists

The Committee considered a resolution from the N.E. Metropolitan Regional Committee for Hospital Medical Services drawing attention to the grave shortage of hospital pharmacists and to the need to pay them higher salaries.

The CHAIRMAN pointed out that it was not the policy of the Committee to negotiate salaries for ancillary staff but to recommend that they should negotiate their claims for themselves.

Dr. MAYON-WHITE said that this was the Committee's concern in so far as it brought about a curtailment of the hospital service owing to a shortage of staff. This was an occasion to press the pharmacists' difficulties on the Ministry.

Dr. GREY-TURNER said that the Ministry knew that hospitals were finding difficulty in getting ancillary staff, and it had set up a committee to examine the matter. Its terms of reference were to consider the future organization and development of hospital scientific and technical services in National Health Service hospitals, and the broad pattern of staffing required, and to make recommendations.

The Committee agreed that the matter should be taken up with the Ministry of Health.

The Bromsgrove General Hospital also supported Redditch, continued Mr. Doran. Redditch had a population of 35,960, and was being converted into a new town of approximately 90,000 people. That would take place at the rate of 3,500 people a year over the next 15 years. The regional board had stated that it could not build a new hospital for the new town in the next ten years, by which time the population of Redditch would have risen by 35,000 to 70,960. Therefore, in ten years' time the population relying on the hospital at Bromsgrove would have risen to 167,450.

Dr. MAGGS supported the resolution and suggested that consultation should take place at national level to see that adequate hospital accommodation was available in areas where redevelopment was contemplated. Dr. OWEN WILLIAMS said that if population growth was necessary in certain areas it was equally necessary for services to be established in these areas.

The committee supported the resolution.

Contract of Service

Dr. D. L. D. LAMONT spoke to the following motion by Mid-Hertfordshire which was among those not discussed by the Representative Body and referred to the Council: "That this Representative Body rejects the concept of 'whole-time' service defined in the third sentence of para. 22 of Appendix III of Annual Report of Council." All con-

† The third sentence of para. 22 of Appendix III of the Annual Report of Council read as follows: "'Whole-time' service means continuous availability, with unlimited hours of work, upon a fixed salary." The last sentence of the same paragraph read: "The maximum contractual week might then be defined as one of 10 notional half-days, and any service provided over and above this would require a separate (additional) contract."

tracts should be based on the criteria of the last sentence of that paragraph."

Dr. Lamont said that Mid-Hertfordshire rejected the present concept of full-time service.

The CHAIRMAN informed the Committee that the ten-tenths system was still being examined. Dr. H. L. LEAMING said there was a danger of approving the ten-tenths system by adopting the motion. He moved as an amendment "that further urgent consideration be given to the feasibility of the ten-tenths payments system."

Dr. LAMONT accepted the amendment, and the motion, as amended, was carried.

Review of Hospital Medical Staffing

Mr. R. COWLEY moved the following motion by Cleveland and Middlesbrough which had not been discussed at the A.R.M.: "That this Representative Body demands that the figures arising from the review of hospital medical staffing as modified and brought up to date following the Platt Committee report be published."

He suggested that the Minister of Health should concentrate on keeping doctors in this country, but that he would not be successful unless they could see that there were jobs for them.

Dr. HARVEY-SMITH said that the motion did not go far enough. It was all very well having figures published, but action was needed to implement them.

The CHAIRMAN drew attention to an amendment in the name of Redbridge which read: "Delete all words after 'brought up to date' and add: '... bearing in mind the urgent need to reduce waiting lists, and also to take into account the inpatient and outpatient work load, and, where necessary, to institute an immediate increase in consultant establishment.'"

The amendment, he said, seemed to strengthen the motion appreciably.

Mr. COWLEY agreed, and the motion, as amended, was carried.

Staffing of Accident and Emergency Departments

Dr. R. M. WARREN moved the following motion by Southampton that had not been discussed by the A.R.M.: "That this Representative Meeting, while appreciating the efforts of the Central Consultants and Specialists Committee and the Joint Consultants Committee, instructs Council to press vigorously for the implementation of a career structure in the 'casualty (emergency) service' in hospitals recommended in the memorandum submitted to the Central Consultants and Specialists Committee by the Senior Casualty Officers Subcommittee."

Dr. Warren said that the variety of skill required in the casualty service warranted a special study, and in order to obtain doctors of the right calibre it was necessary to offer those specializing in this field the prospect of reaching the top of the tree. An advantage in having consultant posts in the casualty service would be that the standard of treatment of minor injuries would be raised. Secondly, there would be uniformity of approach to a wide variety of specialized subjects, and the doctor in charge of the casualty department could negotiate with other specialized units on an equal footing.

Mr. J. C. WATTS (North Bedfordshire) supported the motion. Accidents, he said, were the commonest cause of death up to the fifth decade, the commonest cause of admission of males to hospital, and the commonest cause of emergency attendance at provincial hospitals and in suburban general practices, though not at teaching hospitals.

Mr. Watts said that at present undergraduates received one lecture on trauma during the elementary clinical period. In the surgical revision lectures there were three lectures on orthopaedics, including one on trauma. In postgraduate education in 1967 there were 69 lectures and courses, of which one was on accident and emergencies. Trauma was the only branch of surgery which embraced the whole body, yet there was very little known about it. Mr. Watts suggested that accident surgery would provide a satisfactory career for a consultant, and if consultants were appointed to work whole-time in accident departments able graduates would be attracted to fill the junior posts, as there would be prospects of advancement.

Mr. MYLES GIBSON suggested that the Committee would be unwise to rush into any major policy decision on this matter. He proposed that a small subcommittee should be appointed to assess the existing position in relation to the Platt Committee recommendations.

Mr. T. M. HENNEBRY said he thought a proposal for full-time consultants in casualty work should be viewed with suspicion. Some years ago there had been a plethora of senior registrars trained in orthopaedics, and for a short time they had been appointed as consultants to accident departments, but by and large it had not been a success. Though he would support anything which would strengthen the accident service, Mr. Hennebry said he was not convinced that this suggestion was the right way to go about it.

Mr. WATTS referred to what he described as a curious paradox in the Platt Report on medical staffing. It suggested that care of trauma was too big a subject for one man to tackle, yet it should be the part-time hobby of a surgeon. The two suggestions were incompatible. In his view there was a place for a specialist in trauma.

Dr. GLYN JONES supported the motion. The accident and emergency service was the most important part of the hospital service, he said, and should be recognized as a specialty in its own right. Dr. OWEN WILLIAMS thought there was a strong case for setting up a subcommittee to look at the problem. The need for a doctor of consultant status to look after casualties was self-evident. Dr. MAYON-WHITE said that he also was in favour of a career grade for casualty surgeons.

The CHAIRMAN said he did not think that the Committee had ever really studied the problem, and he asked the mover and seconder of the motion if they would agree to the suggestion that a subcommittee should be set up to study the matter.

Dr. WARREN and Mr. WATTS agreed, and Mr. Watts emphasized the urgency of the problem, because, he said, those currently in charge of accident departments received their training in trauma during the war. There were no replacements in the line.

The Committee agreed to appoint a subcommittee to study the question as a matter of urgency and to report.

Consultant Training

Dr. K. C. ROBINSON moved the following West Hertfordshire motion that had not been discussed at the A.R.M.: "That this Meeting regrets the omission from Appendix IV of the Annual Report of Council of any mention that some experience in general practice should be a requirement of the training of a consultant."

Appendix IV, Dr. Robinson said, examined the existing system of postgraduate education in relation to consultants, medical teachers, research workers, general practitioners, and public health medical officers. Referring to the training of consultants, Dr. Robinson said that it was well known that a trainee was expected to hold a series of posts, including possibly some time in a research post, before he applied for a consultant vacancy. The West Hertfordshire Division thought that time should be allowed for some work in general practice.

Dr. R. C. GREENBERG said it was deplorable that a doctor could become a consultant without ever having set foot in a patient's home. It was an important motion in relation to improving communication between doctor and patient.

Mr. W. DRUMMOND said that the concept of every consultant doing a period in general practice was excellent, but it was very doubtful whether there was time for it during training. A young man had to do many other things in climbing up the ladder in the hope of becoming a consultant. Mr. Drummond suggested that time in general practice might be better spent at student level.

Dr. ASTLEY opposed the motion. He said that he had always believed that the alleged benefits of a consultant doing a few weeks in general practice were emotionally exaggerated. Mr. MYLES GIBSON agreed with Mr. Drummond. While he sympathized with the content of the motion, it was a matter that was increasingly being taken into account in the undergraduate curriculum.

Dr. J. B. S. MORGAN said it was difficult to insist on a period in general practice. There were many factors which determined a man's career. It was true that those who had had general practice experience and who had become consultants usually held the view that it was of great value. Dr. RIDGE said that a period of training in general practice could serve a vital function. General practitioners derived more help from consultants who had gained practical knowledge of general practice problems than they obtained from consultants who had not had this experience. The patients' interests would be improved by a closer understanding by consultants of the problems which general practitioners faced. Dr. MAYON-WHITE said it was becoming increasingly impossible during the postgraduate training years for consultants to spare time for other things. Valuable as experience in general practice was it must be gained by the student before qualification.

The motion was lost.

Care of Young Chronic Sick

Dr. GREENBERG moved an A.R.M. motion by East Herts: "That urgent attention should be given to the provision of special centres for the care of the young chronic sick."

There was an amendment by Finchley and Sheffield to add the words: "which should take into account their need to live as full a life as possible in close contact with their own families."

Dr. Greenberg said it was necessary to deal with the problem of the young chronic sick in a more humane way than in the past. It was quite wrong to take them away from their family setting. They were human beings who should not be excluded from the community.

Dr. WEDGWOOD said that everyone must be sympathetic with the idea put forward, but the trouble with the motion was that it referred to the provision of "special centres" for the care of the young chronic sick. The problem was already being dealt with in most centres. Geriatricians were aware of the problem. In his view many of the young chronic sick fitted in quite well to geriatric hospitals.

Dr. MAGGS supported the motion. He thought the number of young chronic sick would increase in the future, particularly as a result of road accidents. Head injuries in young people were more frequently encountered. Unfortunately, general hospitals were often unable to go on caring for these people, and a number of them were sent inappropriately to a psychiatric hospital.

Dr. A. T. FORD supported the motion, particularly bearing in mind young patients suffering from malignant disease. They were often unsuitable for admission to geriatric units.

Dr. ASTLEY asked what the mover of the motion had in mind by "young chronic sick." Dr. GREENBERG replied that he had in mind those with congenital disorders, but he thought that the Sheffield Division, who were joined in the amendment, had in mind "lame brains." There was, he suggested, a need for special provision to meet the problem, but he emphasized that such special provision need not inevitably mean hospital beds.

The motion was carried.

Preregistration Posts

Dr. I. MCKIM THOMPSON moved a motion by Birmingham that had not been discussed at the A.R.M.: "That this meeting is of the opinion that any provisionally registered practitioner shall be allowed to take his preregistration posts in any hospital approved for the purpose, regardless of its geographical location."

He said that in March the following notice was posted in Birmingham University: "After a recommendation from the General Medical Council that universities should supervise preregistration appointments of their medical graduates much more closely than in the past, the Board of the Faculty has passed the following resolution: 'That medical graduates of this university are normally required to complete their preregistration service in approved posts at hospitals under the jurisdiction of the United Birmingham Hospitals and the Birmingham Regional Hospital Board, or in Salisbury, Rhodesia.' The notice had concluded: 'Exceptions from this rule will be few and will require the personal approval of the Dean.'"

An immediate protest had been made by local members of the B.M.A. at this direction of labour and unheralded reduction of per-

sonal freedom. After that protest a press statement was made by a senior member of the faculty which stated that posts existed which could never be filled. Furthermore, "many students leave the area for extraneous reasons such as married quarters. The more remote areas have been able to entice married men away with the offer of a nice little love nest."

Two extremely important points arose from those statements, continued Dr. Thompson. Firstly, any attempt to direct labour on any grounds must be resisted. If preregistration jobs were once allowed to be filled by compulsory drafting it would be only a matter of time before more senior posts were filled on the same basis. Secondly, it was probably significant that hospitals with poor amenities for resident staff (and he included married quarters) were finding it increasingly difficult to fill junior hospital posts. "Let them correct these faults and they will have a much easier time in filling their posts," he added.

Dr. Thompson agreed with the General Medical Council that adequate postgraduate supervision was long overdue, and, while in no way advocating broodiness, the preregistration doctor must be able to choose the place where he decided to nest.

Dr. GREY-TURNER said that the attention of the Medico-Legal Subcommittee had already been drawn to the notice. Legal opinion had been taken, which was that the notice was *ultra vires*.

The motion was carried, and the Committee agreed that a statement making the position quite clear should be drawn up and published.

Accepted Motion

The CHAIRMAN drew attention to the following motion, standing in the name of Mid-Essex, that had been an accepted A.R.M. motion: "That the consultant selection committees should be balanced, in order to ensure that the application of the registrar with regional experience is always considered equitably."

Mr. ALEX LYALL moved an amendment in the name of Renfrewshire to add at the beginning of the motion: "When consultant appointments are being made in the teaching hospitals, the consultant selection committees . . ."

Mr. D. BROWN urged the Committee to reject the amendment. He thought the motion should stand, so that registrars with regional experience were given a fair chance, whether applying for teaching hospital appointments or other hospital appointments.

The Committee agreed to allow the original motion to stand, and to consider as a separate motion the motion by Mid-Essex as amended by Renfrewshire—namely, "When consultant appointments are being made in the teaching hospitals, the consultant selection committees should be balanced in order to ensure that the application of the registrar with regional experience is always considered equitably."

The motion was carried.

Dr. A. N. MATHIAS, Chairman of the Representative Body, said he greatly regretted the truncation of hospital business at the Annual Representative Meeting in Bristol. The new procedure for the conduct of business at the meeting would prevent that sort of thing happening again. In addition to constitutional suggestions which had been

approved the Agenda Committee had already met and had suggested certain changes in Standing Orders which would facilitate matters. If the Standing Orders were agreed by the Representative Body what occurred at Bristol would be most unlikely ever to happen again. Subject to there being no major medico-political crisis to be considered, he had promised the Chairman of the Committee that hospital business would be taken after the preliminary business on the first day of the A.R.M. in 1968.

The Committee agreed that the following motion in the name of Brighton and Mid-Sussex be submitted to the Hospital Junior Staff Group Council for consideration: "That, in view of the unsatisfactory career structure of Junior Hospital Staff, it is proposed that in future 75% of the appointments to the ranks of registrar and senior registrar should be linked to major centres."

The following amendment to the motion, standing in the name of Renfrewshire, was sent to the Regional Committee for Hospital Medical Services for comment and report to the Central Committee: "Add at the end of motion: ' . . . but that there be no diminution in size of the total registrar establishment of the area, without prior agreement with the district hospitals, and that there should be rotation of registrars between the teaching and district hospitals.'"

A motion in the name of Winchester, urging the B.M.A. to take steps to persuade the Ministry of Health to permit independent work studies to be carried out within all branches of the National Health Service, was carried.

Hospital Building

The Committee considered the following motion by St. Marylebone that had not been discussed by the A.R.M.: "That this Meeting deprecates the present practice of money obtained from the sale of valuable hospital sites being put directly into the Treasury, and strongly recommends that these monies should be credited to the funds of the hospital or hospital services concerned."

Mr. ALAN SMALL said that he had always thought that if some arrangement could be made with the Treasury for compensation to be paid to the group when a hospital was disposed of it would encourage hospital management committees to be more efficient. Dr. WHITESIDE supported the motion.

Dr. SKENE pointed out that a hospital was not owned by a group. It was Crown property, and if it was not required for Crown purposes the Treasury deployed the resources for other Crown purposes.

The motion was carried.

Other A.R.M. Motions

The following motion by South Staffs was considered: "That whole-time senior hospital staff be granted tax incentives equivalent to their part-time colleagues."

The CHAIRMAN said that if the Committee supported the motion it would be asking the negotiators to undertake an almost impossible task.

The motion was lost.

A motion by Brighton and Mid-Sussex, noting that the value of conferences such as the Hospital Medical Staff Conference was

largely vitiated by the absence of previously notified specific motions for debate, was referred to the Arrangements Subcommittee for consideration.

The Committee agreed to look at the following motion in the name of St. Marylebone in association with the report of the Royal Commission on Medical Education: "That this Meeting recommends that non-teaching or peripheral hospitals should be used much more than they are for the teaching of medical students, and it would be desirable for all medical students to spend part of their curriculum outside a teaching hospital where they would obtain wider experience of medicine and surgery than is available at the overspecialized teaching hospitals of the present day."

A motion on the same subject in the name of Tower Hamlets, "That this Meeting considers that where it is proposed that a

non-teaching hospital should be designated to a teaching hospital there, should be adequate consultations with local practitioners before any action is taken," was accepted, provided "local practitioners" meant all local members of the profession concerned.

A motion by Morpeth and Blyth, expressing concern at the deplorable lack of geriatric beds in the County of Northumberland, particularly in the Wansbeck area, and censuring the Ministry of Health for failing to make adequate provision over a period of 18 years, was submitted to the regional committee for consideration.

The CHAIRMAN reported that a recommendation in a motion by Havering, that a standard discharge summary form giving details of the diagnosis, treatment, and follow-up recommendations be used, was being dealt with.

Similarly, he said that action was being taken on a motion by Liverpool that completion of cremation certificates Parts B and C should attract a fee for all doctors.

The Committee gave general support to the following motion by Dunbartonshire in the sense that it referred to emergency calls: "That there should be an investigation into a proper method of recognition for the services of a consultant who undertakes work in a general-practitioner unit."

The Committee also supported the general principle contained in a motion by Greenwich and Deptford asking the Minister of Health to make post-auricular hearing aids prescribable by consultants in the N.H.S., and referred the motion to the Otolaryngologists Group Committee for comment.

The remaining motions were submitted to the Executive Subcommittee for consideration and report back to the Committee.

General Practice Finance Corporation

The Ministry of Health has stated that since the General Practice Finance Corporation began to consider applications from general practitioners in May it has made 141 loans totalling £683,000. It has also agreed to make loans totalling nearly £800,000 which had been approved under the Group Practice Loans Scheme but had not been issued when that scheme was wound up in May. About 10 new applications for loans are received by the Corporation each week.

The first report of the General Practice Finance Corporation* was published on 23 October. It covers only the first few months of the Corporation's existence, before it had made any loans.

The Corporation was established by the Government to implement the agreement between the Minister of Health and the general practitioners' representatives in their discussions on the family doctor service (*Supplement*, 5 June 1965, p. 238) that an independent corporation should be established with powers to make loans to doctors for the purchase, erection, and improvement of practice premises, and with a reserve power to make loans for the purchase of equipment.

The members of the Corporation are Sir Frederick A. Hoare, Bt. (Chairman), Sir William Mullens (Deputy Chairman), Lord Crook, Dr. F. Lishman, Sir William Murrie, Mr. A. E. Orchard-Lisle, Dr. S. Wand. The Corporation operates within a scheme

approved by the Health Ministers and the main purposes for which it makes loans are (1) to provide, or to acquire a share in, practice premises; (2) to alter, enlarge, improve, or repair practice premises; (3) to acquire land required for the erection of, or in connexion with the use of, practice premises; and (4) to repay a loan raised earlier for any of these purposes.

Security

The report states that one of the Corporation's important functions will be to make loans on security which might not be considered adequate when judged by normal commercial standards. At the same time the Corporation had to bear in mind the requirement of the relevant section of the N.H.S. Act 1966 that it should so discharge its functions "that, taking one year with another, its revenue shall be sufficient to meet its expenses including allocations to reserve." The Corporation has decided therefore that, while it "would be willing to consider loans of up to 100% of the valuation of the premises or land and would, if required, add approved costs to this amount, it would, wherever possible, require the security of a legal mortgage."

Loans will, nevertheless, be made in suitable cases, even though little security can be given other than the borrowing doctor's covenant to pay coupled with a guarantee from a third party and, possibly, the assignment of an endowment policy.

* *Report of the General Practice Finance Corporation for the period 21st November 1966 to 31st March 1967.* H.M.S.O., London, 1s. 6d.

Surrey Public Health Appointment

After a meeting called by the British Medical Guild on 26 October, to which all medical officers of the Surrey County Council were invited, a letter was sent by the Guild to the County Council criticizing the circumstances in which the appointment of the new county medical officer of health was made. "Any appointment of a chief officer by an authority in such circumstances and from a restricted field of applicants could scarcely be expected to inspire confidence in the staff of the department concerned," it said.

The letter went on to state that the medical officers of the Surrey County Council had

asked that an immediate request be made by the British Medical Association to the Minister of Health and to the Secretary of State for Education and Science for an inquiry into all aspects of the appointment.

Owing to the British Medical Guild's appeal to doctors not to apply for public health service posts until an acceptable offer has been made in response to the profession's pay claim, it is known (the Guild's letter states) that many medical officers "admirably fitted" for the Surrey appointment refrained from replying.

Tuberculosis and Diseases of Chest

A meeting of the Tuberculosis and Diseases of the Chest Group Committee of the B.M.A. was held on 17 October. Dr. T. W. Davies, who had been chairman of the Group Committee for many years, did not seek re-election.

Dr. G. F. EDWARDS, Harrogate, was appointed Chairman, and Dr. W. D. GRAY, Liverpool, Deputy Chairman. The Chairman and Deputy Chairman were appointed to represent the Committee on the Central Committee for Hospital Medical Services.

The Group Committee paid tribute to Dr. Davies's services during his tenure of the chair.

B.M.A. Nuffield Library

The Library Service is available to all members of the Association resident in Great Britain and Northern Ireland (and by special arrangement to members of the Irish Medical Association). A copy of the library rules will be forwarded on application to the Librarian at B.M.A. House.

The following books have been added to the Library:

- Bell, E. T., and Loraine, J. A.: *Recent Research in Gonadotrophic Hormones.* 1967.
- Bernstein, N.: *The Co-ordination and Regulation of Movements.* 1967.
- Cargill, D.: *Accidents in the Home.* 1967.
- Cargill, D.: *How to Avoid a Coronary Thrombosis.* 1967.
- Carter, G. S.: *Structure and Habit in Vertebrate Evolution.* 1967.
- Cartwright, A.: *Patients and their Doctors.* 1967.
- Croll, N. A.: *Ecology of Parasites.* 1966.
- Edeiken, J., and Hodes, P. J.: *Roentgen Diagnoses of Diseases of Bone.* 1967.
- Elkes, A., and Thorpe, J. G.: *A Summary of Psychiatry.* 1967.
- Feinstein, A. R.: *Clinical Judgement.* 1967.
- Fishlock, D.: *The New Materials.* 1967.
- Fripp, A. T., and Shaw, N. E.: *Club-foot.* 1967.
- Gibson, J., and French, T.: *Nursing the Mentally Retarded.* 1967.
- Goldman, M.: *A Nurse's Guide to the X-ray Department.* 1967.
- Gray, C. H. (Editor): *Laboratory Handbook of Toxic Agents*, 2nd. edition. 1966.
- Grieve, J. M.: *Cancer in the Cape Division, South Africa.* 1967.

Association Notices

Armed Forces Committee
Nomination of Members for Co-option

The constitution of the Armed Forces Committee was amended at the Annual Representative Meeting of the Association in July 1967 to allow greater representation of serving medical officers, especially younger members, by means of co-option to the Committee. The Committee may now co-opt two representatives of the rank of major or equivalent (lieutenant-commander or squadron leader) or below, one of whom should preferably be of specialist status, from the medical branch of each of the Services.

Notices appeared in the *B.M.J.* (Supplement, 26 August and 16 September, pp. 124 and 130 respectively) inviting serving medical officers to nominate members of the Association in the armed Forces in these ranks for co-option to the Committee.

At its meeting in October the Armed Forces Committee considered the nominations received and the following have been co-opted to the Committee:

Army.—Major T. R. Austin, specialist in anaesthetics at the Cambridge Military Hospital, Aldershot.

Navy.—Surgeon Lieutenant-Commander J. A. M. Wright, medical specialist at the Royal Naval Hospital, Plymouth; Surgeon Lieutenant-Commander D. S. Wright, G.D.O., H.M.S. *President*.

R.A.F.—Squadron Leader J. B. Crowe, Consultant Radiologist, P.M.R.A.F. Hospital, Halton, Bucks.

The Committee thought it was most important that non-specialists should be represented from each of the Services, and it decided to seek further nominations for the non-specialist vacancy in the Army and in the R.A.F. representation.

Serving medical officers in the Army and the R.A.F. are therefore invited to nominate members of the Association in the rank of major, squadron leader, or below of non-specialist status for co-option to the Committee. It is hoped that those nominated would have a reasonable expectation of being available to attend meetings in London in the foreseeable future.

Nominations should be sent to the Secretary of the Association by 23 December 1967 for subsequent consideration by the Armed Forces Committee.

DEREK STEVENSON, *Secretary*.

Branch and Division Meetings to be Held

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

ARGYLL AND BUTE DIVISION.—At Cairnbaan Hotel, Sunday, 12 November, 11 a.m., Autumn meeting, luncheon and address by Lord Birsay: "General Medical Services in the Highlands and Islands."

Dr. S. J. Hadfield (Scottish Secretary, B.M.A.) will be present. Ladies are invited.●

BARNET DIVISION.—At Outpatients' Department, Barnet General Hospital, Tuesday, 7 November, 8 p.m., clinical meeting.

BLACKBURN DIVISION.—At Committee Room, No. 1, Town Hall, Tuesday, 7 November, 8.15 for 8.30 p.m., B.M.A. lecture by Sir Theodore Fox: "Population and Family Planning." Ladies are invited.

BRADFORD DIVISION.—At Bradford Royal Infirmary, Wednesday, 8 November, 8.15 p.m., general meeting.

BRENT DIVISION.—At St. Andrew's Hospital, Tuesday, 7 November, 8.30 p.m., clinical evening presented by hospital consultants.

BUCKINGHAMSHIRE DIVISION.—At Archery Unit, Stoke Mandeville Hospital, Friday, 10 November, 8.30 p.m., B.M.A. lecture by Professor W. J. H. Butterfield: "Community Medicine of the Future." (Preceded by election of representatives to Annual Representative Meeting, 8.25 p.m.)

BURY DIVISION.—At Bury General Hospital, Saturday, 11 November, annual dinner.

COVENTRY DIVISION.—At Outpatient Department, Coventry and Warwickshire Hospital, Tuesday, 7 November, 8.30 p.m., "spot diagnosis" evening, followed at 9.30 p.m., in Physiotherapy Department, by discussion of cases.

CUMBERLAND DIVISION.—At Cumberland Infirmary, Carlisle, Friday, 10 November, 8 p.m., annual general meeting.

DEWSBURY DIVISION.—At Three Nuns Inn, Mirfield, Thursday, 9 November, 8 for 8.30 p.m., annual dinner.

DUNBARTONSHIRE DIVISION.—Monday, 6 November, visit to Broadcasting House, Glasgow.

EAST YORKSHIRE BRANCH.—At Postgraduate Centre, Hull Royal Infirmary, Wednesday, 8 November, 8.30 p.m., B.M.A. lecture by Professor Henry Miller: "Pain in the Arm."

GLOUCESTERSHIRE BRANCH.—At Board Room, Gloucestershire Royal Hospital, Gloucester, Thursday, 9 November, 6.30 p.m., meeting, Dr. A. E. Tinkler: "The Recrudescence of Venereal Disease or the Copulation Explosion." (Followed by dinner at New Country Hotel.)●

GUILDFORD DIVISION.—At School of Nursing, St. Luke's Hospital, Tuesday, 7 November, 8 p.m., jointly with Guildford Postgraduate Medical Centre, clinical meeting, followed at 8.45 p.m., Coyle Hall, by discussion of cases.

HALIFAX AND TADMORD DIVISIONS.—At White Swan Hotel, Halifax, Thursday, 9 November, 8.30 p.m., Dr. J. Todd: "Drug Addiction."

HARROW AND HILLINGDON DIVISION.—At Whittington Hotel, Pinner, Tuesday, 7 November, 8.45 p.m., Dr. S. T. Hayward: "Motoring Through Russia" (illustrated). Guests are invited.

HOLLAND DIVISION.—At Westland Hall, Boston General Hospital, Wednesday, 8 November, 8.15 p.m., Mr. K. F. Wood: "Diseases of the Small Bowel." (Followed by buffet supper.)●

HUDDERSFIELD DIVISION.—At Rest Room (next to Chapel), South Entrance, Royal Infirmary, Lindley, Tuesday, 7 November, 8.30 p.m., general meeting followed by film: "And Then There Was One."

ISLE OF WIGHT DIVISION.—At Medical Centre, St. Mary's Hospital, Newport, Thursday, 9 November, 8.30 p.m., B.M.A. lecture by Dr. J. Cyriax: "Manipulative Medicine."

LIVERPOOL DIVISION.—At Exchange Hotel, Tuesday, 7 November, 8 for 8.30 p.m., annual general meeting, followed by videotape discussion: "Treatment of Depression in General Practice."

MID-ESSEX DIVISION.—At Academic Unit, Chelmsford and Essex Hospital, Wednesday, 8 November, 8.30 p.m., annual general meeting.

MID-GLAMORGAN DIVISION.—At York Hotel, Bridgend, Monday, 6 November, 8 p.m., at invitation of Pharmaceutical Society, taped lecture on "Diuretics" followed by discussion.●

MID-HERTS DIVISION.—At Medical Centre, St. Albans City Hospital, Friday, 10 November, 8.30 p.m., annual clinical demonstration.

NORTH BEDFORDSHIRE DIVISION.—At Medical Institute, Thursday, 9 November, 8.30 p.m., jointly with Bedford Medical Society, Wing Commander P. J. Stevens: "Medical Investigation of Aircraft Accidents."

NORTH NORTHUMBERLAND DIVISION.—At Community Centre, Berwick-upon-Tweed, Tuesday, 7 November, 8.30 p.m., film: "The Anaemias."

NUNEATON DIVISION.—At Gymnasium, Manor Hospital, Tuesday, 7 November, 8 for 8.30 p.m., symposium by Mr. A. Gourevitch, Dr. J. Howel Jones, Dr. E. E. Jones, Dr. A. W. Robinson: "Peptic Ulcer."

ROTHERHAM DIVISION.—At Brecon Hotel, Monday, 6 November, 9 p.m., B.M.A. lecture by Dr. Brian Inglis: "Fringe Medicine." (Preceded by supper, 7.45 for 8 p.m.)●

SALISBURY DIVISION.—At Pembroke Arms, Wilton, Saturday, 11 November, 7 p.m., annual dinner and lecture, Dr. K. J. Kilka: "Coma and Consciousness."●

SOUTH BEDFORDSHIRE DIVISION.—At Halfway House, Tuesday, 7 November, 8 for 8.30 p.m., annual dinner. Principal guest, Dr. Derek Stevenson (Secretary, B.M.A.). Guests are invited.●

SOUTH MIDDLESEX DIVISION.—At Skyway Hotel, Saturday, 11 November, 7 p.m., annual dinner dance.●

SOUTH SHIELDS DIVISION.—At General Hospital, Wednesday, 8 November, 8.30 p.m., Professor S. Shuster: "The Skin and Gut, Further Developments in Dermatological Mythology."

STOCKPORT DIVISION.—At Alma Lodge Hotel, Thursday, 9 November, annual dinner dance.●

WALSALL DIVISION.—At Hollies Club and Hotel, Cannock, Thursday, 9 November, 8.15 p.m., joint supper meeting with Cannock Medical Society, Dr. B. L. Pentecost: "Acute Coronary Care." Guests are invited.●

WIGAN AND LEIGH DIVISIONS.—At Haigh Hall, Haigh, Friday, 10 November, annual dinner and dance.●

WORCESTER AND BROMSGROVE DIVISION.—(1) At Board Room, Worcester Royal Infirmary, Monday, 6 November, 8.30 p.m., meeting to elect representatives and to discuss problems in hospital services in North Worcestershire. (2) At Gifford Hotel, Worcester, Saturday, 11 November, 7.45 for 8.15 p.m., annual dinner. Guest speaker, Mr. David Franklin.●

General Medical Services Committee

How to make local medical committees more democratic was again a matter of debate in the G.M.S. Committee. Some of the ways in which the changeover to the metric system will affect prescribing were described in a Ministry of Health memorandum which was the subject of a preliminary discussion. An inquiry of local medical committees showed that 10% would like general practitioners in their area to have better facilities for open access to hospital pathology departments and 20% would like better access to radiodiagnostic departments. More than 30% would like more access to electrocardiography and physiotherapy. The Committee did not come to a decision on a motion proposing that postgraduate education sessions should in no way be connected with general practitioners' career earnings, including seniority payments. With the support of the Public Health Committee, the G.M.S. Committee is again to ask the Ministry of Health to encourage local health authorities to provide domiciliary physiotherapy services. The Ministry is also to be pressed to provide an admissions bureau for emergency admissions to mental hospitals in Greater London. The problems for general practitioners in dealing with heroin addicts under the new legislation were discussed.

A Meeting of the General Medical Services Committee was held on 26 October. Dr. J. C. CAMERON was in the chair.

A report of the death of Dr. K. S. Maurice-Smith, of Ely, who had been a member of the Committee from 1952 to 1964, was received with deep regret. The Committee paid tribute to Dr. Maurice-Smith's services to it and to the profession.

Appointment System

The Committee considered a letter from the Inner London Local Medical Committee stating that it had received a complaint from a London doctor that general practitioners who had an appointments system were being greatly troubled by patients without appointments who wanted to be seen on the day they attended. The doctor had suggested that the Ministry of Health should tell the public that patients had no right to be seen without an appointment unless their condition was urgent.

The Inner London Local Medical Committee supported the doctor's complaint, and asked the G.M.S. Committee to consider "arranging with the Ministry of Health for the preparation of an appropriate notice for doctors' waiting-rooms, and for its eventual circularization to practitioners by executive councils, and for the position to be brought to the notice of patients by all other possible means."

Dr. D. R. COOK thought that the complaint was fully justified, and asked for the Committee's support.

The Committee agreed to draw the Ministry's attention to the matter.

Constitution of Local Medical Committees

The Committee considered the Ministry of Health's comments on the draft model scheme for the constitution of local medical committees, drawn up by the Constitution Subcommittee of the G.M.S. Committee, together with a revised draft scheme for the constitution of Liverpool Local Medical Committee.

Dr. A. SPEAKMAN said that there were certain points which he would like to have included in the model constitution to offset criticism from the electorate that it had insufficient voice in the running of the local medical committee. He referred to the question of the terms of office of members of the local medical committee and to the appointment of officers. There was often a belief among the

electorate that the chairman of the local medical committee, once elected, would remain in the chair for many years. There should, he said, be a clause in the model scheme to ensure that the electorate was free to change the chairman if it so wished. The object was to make sure that the process was democratic. It would then be up to the electorate to use it.

Dr. Speakman thought that there should be a clause in the model constitution to the effect that the local medical committee must meet regularly. He also said that there should be provision for extraordinary meetings of the committee.

Dr. A. ELLIOTT agreed that local medical committees must be run democratically and be seen to be democratic. Four years ago, he said, as a result of a decision of the Annual Conference of Representatives of Local Medical Committees, a committee had been set up to look into this, and it had met many times. Every point raised by Dr. Speakman had been considered by that committee. The G.M.S. Committee had no right to impose anything on local medical committees. It could only try to persuade all local medical committees to conduct their affairs by the highest standards. A survey had been carried out, and it appeared that many local medical committees were not elected democratically. It was up to the G.M.S. Committee to persuade local doctors to change the situation.

Dr. Elliott said he would have wished to see other things included in the model constitution, but in its existing form it was a big step forward from the practice in some areas. Attention was being drawn to the situation, and it was now rare to find doctors who did not know about their local medical committee. It was a matter of education. The model constitution was not mandatory and could be adjusted to local circumstances. Revised constitutions would have to be submitted to the Ministry for approval.

Combined Posts

Dr. R. A. KEABLE-ELLIOTT pointed out that policy varied from place to place. In some local medical committees the secretary was also the clerk to the executive council, and this often worked well, but in these circumstances there needed to be a medical public relations officer, because a doctor preferred to discuss matters with a doctor.

Dr. G. CORMACK did not agree that it was a good idea for the secretary of a local medical committee also to be the clerk of the executive council. He thought it could lead to empire-

building, and create the impression that the powers of the clerk of the executive council were unlimited.

Dr. R. B. L. RIDGE said that the Committee must bear in mind the true nature of a local medical committee. It was an autonomous local professional committee. It was vital in the interests of general practice that this autonomy should be preserved. But under the National Health Service Act there were certain statutory functions to be discharged by local medical committees, which were recognized by the Minister as being representative of general practitioners in the area. It was solely in relation to the discharge of those statutory functions that the constitution required ministerial approval.

Dr. Ridge suggested that it would be unwise to incorporate in the constitution of a local medical committee, over which the Minister of Health had control, matters which were more appropriate for the standing orders of the committee. The standing orders did not have to be approved by the Minister, and these could include the method of election of the local medical committee and its officers, and rules relating to its meetings and to the conducting of its business, and for the election of representatives on the executive council. These were all matters, said Dr. Ridge, which should be left within the autonomy of the local medical committee. If there was any doubt in an area that the local medical committee was not running its affairs democratically the electorate had its redress at election time.

Dr. SPEAKMAN agreed with Dr. Ridge's comments and suggested that the G.M.S. Committee might draw up a model list of standing orders, which could be given to local medical committees as a guide, together with the model constitution if any committee requested assistance on this matter.

The G.M.S. Committee agreed with Dr. Speakman's suggestion, and decided to consider the matter again later.

Evidence to Review Body

After a debate *in camera* the Committee decided that a statement should be issued on the subject of the submission of evidence to the Review Body. The statement was as follows:

"The Committee heard a statement from Dr. Cameron on the bases on which the evidence was being prepared and the procedure to be adopted before the Review Body. He also explained the cross-representation with those preparing the case for hospital doctors. It was resolved that the document of evidence would be published when the Review Body had reported, and it was assumed that the Ministry of Health would agree that its evidence would be similarly available for publication.

"Dr. Cameron gave an assurance that in the evidence full weight was being given to all the relevant decisions of the Conference of Representatives of local medical committees and of the Representative Body."

Prepaid Postage

The Committee considered the question of the prepayment of postage on doctors' letters referring patients to hospital.

Dr. H. J. EASTES said that the practice varied over prepayment of official postage when returning medical records to executive councils, and he asked why there could not be a uniform practice for all areas in this matter. Dr. A. J. ROWE explained that the Ministry would not take this item out of context of all other practice expenses, because postage was considered to be part of a doctor's normal practice expenses.

The Committee agreed to press the matter with the Ministry.

Dr. H. S. HOWIE WOOD pointed out that there was also a lack of uniformity in the prepayment of postage on letters referring patients to hospital.

The Committee agreed also to discuss this matter with the Ministry of Health.

Metric System

The Committee considered a memorandum from the Ministry of Health setting out the ways in which the medical and pharmaceutical professions would be affected when a change-over to the metric system for prescribing and dispensing took place. The Ministry had stated that regulations would be necessary in connexion with the completion of the change-over.

The memorandum before the Committee was the result of informal discussions between the Ministry of Health and the Pharmaceutical Society, which had been considering the practical steps necessary in a changeover to the metric system. The Ministry asked for the G.M.S. Committee's comments on any aspects which it thought might give rise to difficulty. In the meantime the Ministry was considering the legal aspects of the matter.

Dr. RIDGE called attention to the following extracts from the memorandum.

When prescribing was not done in the metric system, the memorandum stated, an accurate equivalent in metric of the order in grains, drachms, etc., would be dispensed. By using the title of the preparation the doctor would be regarded as having ordered the ingredients contained in 5 ml. or 10 ml. of the preparation to be formulated in the B.N.F., 1968, not the amount in a teaspoonful or tablespoonful, and the respective 5-ml. or 10-ml. volumes would be dispensed. Labels would bear the instruction "One 5-ml. dose to be taken . . ." and a 5-ml. dose British Standard spoon would be issued. Similar instructions would be given for the 10-ml. dose, and a measure would be supplied graduated at 10-ml. dose and permitting the necessary dilution of the stronger adult mixtures of the future.

Dr. Ridge said that it was impossible with that type of vertical measure to get a medical dose. There should be a proper measure which clearly indicated what the dose should be.

The memorandum pointed out that when the quantity ordered or the number of doses specified instead of quantity did not coincide with one of the metric bottle sizes and the round number of doses it contained it would be necessary to establish a practice acceptable to medical opinion. Either the patient could be given a partially filled bottle of medicine, or the quantity or number of doses dispensed could be adjusted by reference to the "Total Quantities Table," so that the patient received a full bottle. If the second alternative were accepted (as pharmacists and probably

patients would prefer) the quantities dispensed and received would be those which doctors would be expected to order when fully accustomed to the new system. Provision could be made for the supply of the odd quantity in essential cases when the doctor expressly indicated it.

Dr. Ridge said that doctors would be in danger of having their freedom to prescribe a predetermined course of treatment limited if courses had to be related to standard-size bottles. The Committee should state its preference for the first alternative.

Dr. Ridge said he did not understand which regulations in the terms of service were being referred to in the following statement in the memorandum, and he hoped that there would be nothing put into the terms of service requiring doctors to prescribe in metric units: "For the dispensing of prescriptions not written in metric, and, where applicable, to those written in metric, consideration is being given to the preparation of regulations under the Weights and Measures Act, 1933, and to requisite changes in the N.H.S. (General Medical and Pharmaceutical Services) Regulations (terms of service)."

The Committee decided to defer further consideration of the memorandum until its next meeting.

Open Access to Diagnostic Departments

The Committee considered a summary of replies from local medical committees to its inquiry about the availability of open access to hospital diagnostic departments.

The inquiry had shown that there was little dissatisfaction among general practitioners over access to departments of haematology, biochemistry, and bacteriology. Just over 10% of local medical committees wanted more facilities in pathology departments, and 20% wanted more facilities in x-ray departments. More than 30% wanted greater access to both electrocardiography and physiotherapy departments, though the doctors in the areas of over 60% of all the committees which had replied had no access at all to those facilities.

One point which had become apparent from the inquiry was the shortage of staff in the various departments. A number of local medical committees had indicated that, though there were sufficient laboratories and hospitals in the area with all the necessary facilities, no access was available because of the lack of staff. This applied particularly to departments of physiotherapy and electrocardiography.

Dr. T. K. COOKE said he thought the figures were too optimistic, because they were provided by those who used the services. For instance, he did not believe that 61% of general practitioners had full access to post-mortem rooms, as was stated in the memorandum. The biggest delays in the National Health Service occurred when investigations were needed. When new hospitals were being built no account was taken of the morbidity in the area. The number of beds should depend on the total number of investigations which were likely to be required in a given area.

Dr. A. ELLIOTT said that the memorandum would be useful evidence in negotiations with the Ministry, and it would also show their constituents that the G.M.S. Committee was

taking action on their behalf. If general practitioners were to work satisfactorily they had to be given the tools to do the job.

Dr. G. MURRAY JONES said that there was a shortage of technicians in Wales, and one reason for that was their low salary. Open access to hospitals would lead to the shortening of waiting-lists for hospitals. However, when a hospital had to decide which work should be curtailed because of shortage of staff it was usually open access to diagnostic departments for general practitioners which was cut down.

Local Matter

Dr. H. GLYN JONES said that if two-thirds of the replies received from local medical committees expressed satisfaction that was a significant number. It was no good saying what would happen if more people used the service: that was impossible to assess, and it was possible only to work on the existing demand. Little could be done by the Ministry to improve the situation. The provision of these services was a local matter: any complaints should be dealt with locally. When there was no access or insufficient access for general practitioners to any of the departments it was up to the local medical committees to find out the reason why. The

facile explanation of shortage of staff should not be accepted without further investigation.

Dr. Glyn Jones said that the local medical committee should immediately ask what the staff establishment was. It should ask what the deficiency in the establishment was and what measures had been taken, and with what success, to bring the establishment up to strength. In the majority of cases the excuse of staff shortage was untrue, because, as had been pointed out, the work reached the departments in one way or another. Naturally there were occasions when this excuse was genuine, and it was usually only a temporary matter, but in such times it was the inpatient work and the outpatient work of the hospital which had to be given priority. The battle should be fought on the issue of principle at local level.

Dr. C. J. WELLS pointed out that local opinion was influenced by Ministry statements. If the Ministry went on repeating that these services were inadequate hospital management committees and regional hospital boards would accept it. He hoped that the memorandum would be sent to the Ministry in an attempt to get it to change its present attitude that open access facilities for general practitioners are satisfactory.

The Committee agreed that doctors should be recommended to take up complaints through local channels.

connexion between the two, said Dr. Speakman.

Wrong Time

Dr. A. A. CLARK said that in theory all would support Dr. Speakman, but now was the wrong time. General practitioners had thrown out merit awards but they had persuaded the Government to include seniority payments as a reward for long experience in general practice. The Government had included postgraduate sessions as part of the terms of the agreement. As a long-term policy the Committee should not accept this, but this was the wrong time to go back to the Ministry. It should be brought up again at a future date.

Dr. MURRAY JONES said that the subject had been discussed before in the context of vocational training for general practice. If the Committee believed that training for general practice was a continuous process then the idea of seniority must be linked with tangible proof that the doctor was making efforts to keep up to date. Experience as a result of years in practice was good, provided it was the right experience, but at the same time the doctor must prove that he was continuing his medical education.

Dr. D. L. WILLIAMS said that there were occasions when it was wiser not to pass resolutions. He thought the negotiators should be allowed to tackle the matter in whichever way they thought fit, in an endeavour to get expenses and payments for doctors undertaking postgraduate education.

Dr. R. W. RAE said that the seniority payment was not an award but a method of payment. This was the only occasion when payment depended on a doctor doing certain courses. The Committee should make it clear that though it had accepted the condition of postgraduate sessions that did not mean it agreed with it.

Review Body's Report

Dr. RIDGE referred to paragraphs 198 and 199 of the Review Body's seventh report: "When we were asked last year to consider the introduction of seniority payments we made clear our view that, if the concept of payment for seniority were to be adopted, it would require radical changes in the present arrangements for payment to general practitioners. This condition is now in process of being satisfied. We also made it clear that our figure of average net income was based on an assessment of what total earnings should be over the whole of the practitioner's career, and therefore allowed already for differences between general practitioners and other professional men in the pattern of career earnings. It follows from this that we have not been able to regard seniority payments as new and extra remuneration."

"The new system will, however, also include additions to the basic practice allowance for vocational training before entry to practice, and for special experience and service to general practice. . . . The proposed allowances for pre-entry vocational training and for special experience and service to general practice would be very much in line with what we have envisaged [in the fifth report], and we have thought it right to regard these as truly additional allowances,

Seniority Payments

Dr. SPEAKMAN moved the following motion: "That this Committee takes the view that postgraduate education sessions should in no way be connected with a doctor's career earnings, which include seniority payments; that postgraduate education is, by virtue of our profession, desirable for all doctors, and that throughout their careers as general practitioners postgraduate education should continue; that it should be in a form suitable to the doctor's own convenience and that it should not further reduce leisure time available or increase the work load, and that there should be payments made such as to make it worth while."

Dr. RIDGE asked whether in the last part of his motion Dr. Speakman meant "payments" to be restricted to expenses. If it intended that there should be some payment in addition to expenses, as suggested in the early part of the motion, and the payment was made by the Ministry of Health through the executive council, then it inevitably became part of career earnings. Also, if the payment was made by the executive council it attracted superannuation at the appropriate rate. Was Dr. Speakman suggesting a completely new type of payment? Or was it limited to expenses only?

Dr. SPEAKMAN explained that the Review Body had indicated the need for incentives for doctors to encourage them to stay in this country, and the need to attract people to enter the profession. The Review Body had said that seniority awards would not be regarded as new and additional payments, but it had added new and additional duties for the doctor in that seniority payments were conditional on the doctor attending an unspecified number of postgraduate education

sessions. The Review Body had stated that seniority payments would be regarded as part of a doctor's career earnings.

In Dr. Speakman's view there was a difference between keeping up to date and postgraduate education. A doctor could keep up to date by reading medical journals and by contact with consultants. But postgraduate education was something which started on the day a doctor qualified and finished on the day he ceased to practise medicine, and from that point of view it was not justifiable to specify a certain number of postgraduate sessions.

Dr. Speakman said that he had specifically used the words "doctor's own convenience." Doctors had undertaken to look after the health of the nation at all times. It was possible that the number of postgraduate educational sessions could become large. Conditions varied in different parts of the country, and the way in which some doctors could organize their work to attend postgraduate sessions might not suit other doctors. The work load would inevitably be increased, and if the Ministry wished to make postgraduate sessions mandatory they should attract additional payment. The opportunities to attend postgraduate sessions would differ for all general practitioners, and for this reason Dr. Speakman thought seniority payments should be excluded from career earnings but should be superannuable.

He said that it was clear from resolutions of the Annual Conference of Representatives of Local Medical Committees and of the Annual Representative Meeting 1967 that general practitioners wanted seniority payments safeguarded, at the same time recognizing the importance of postgraduate educational sessions, but there should be no direct

covering aspects of general practice which have not been recognized in the system of remuneration until now. The Health Departments agreed that we should not on this occasion regard these as being included in career earnings, and we have regarded them as additional to the increased remuneration which we have thought it right to recommend on other grounds."

Dr. RIDGE said the implication of these paragraphs was clear: that even though the Review Body recommended that on the first occasion the seniority payments should be regarded as additional payments, subsequently these payments would inevitably become part of career earnings. Therefore, said Dr. Ridge, it was unlikely that a request to the Review Body for a payment which was not part of career earnings would be successful.

Dr. N. S. MALIMSON emphasized that what annoyed most doctors was that middle-aged general practitioners with years of experience could earn only the same money as the newcomer into general practice.

The CHAIRMAN said that the Minister must not be allowed to impose clinical standards on the profession. But whatever resolution the Committee passed, he said, it would not embarrass the negotiators so long as the term "seniority payments" was left in a broad sense.

The Committee accepted a motion to pass to the next business.

Domiciliary Physiotherapy

The Committee considered a letter from the Ministry of Health in reply to a resolution of the Annual Representative Meeting 1966 concerning domiciliary physiotherapy. The letter stated that while physiotherapy might play a useful role in domiciliary practice it was, in the Ministry's view, a limited one. "Domiciliary practice is an extravagant use of physiotherapists' time because, although physiotherapists can visit and treat six or eight patients a day in their own homes, they can treat over three times as many, and generally more effectively, in a hospital department. For this reason, while there is a widespread demand for more physiotherapists, little encouragement can be given to setting up domiciliary services which might take away physiotherapists from the hospital service and so reduce the number of patients treated at hospital, without making a comparable increase in the number treated in their own homes. We doubt (the letter continued) whether domiciliary services organized by local authorities would attract many physiotherapists who are not working in hospital, because a substantial proportion of physiotherapists employed in hospitals are in fact married women."

Dr. B. D. MORGAN WILLIAMS said that was a fallacy, because there were many married women who would be willing to do physiotherapy in domiciliary visits but who could not work in hospitals.

The letter from the Ministry continued: "You asked whether it was already open to local health authorities to set up a domiciliary physiotherapy service on the lines of the district nursing service, if they so wish. We are advised that the provision of a domiciliary physiotherapy service providing intensive skilled treatment for short periods is not something which would be proper to a local

health authority. Broadly the consideration underlying this view is that in general the intention of the National Health Service Act, 1946, seems to be that 'treatment' should be provided by the hospital service and practitioner services, and that this is to be distinguished from 'care' which a local health authority may provide under Section 28. There may be minor forms of physiotherapy which could reasonably be regarded as part of 'care,' but most physiotherapy given by a skilled physiotherapist is regarded as treatment and outside the scope of arrangements which a local health authority may make under the Section."

The Committee was informed that the Public Health Committee had considered the matter, and, while it had recognized that the existing shortage of physiotherapists might make the provision of a domiciliary service difficult, it had thought that the Ministry had "not paid enough regard to the needs of patients in remote areas and those who are recovering from such conditions as strokes who cannot reach hospitals for treatment as outpatients." The Public Health Committee had pointed out that in Scotland a domiciliary physiotherapy service had been established and was working satisfactorily. The Public Health Committee also believed that domiciliary physiotherapy would provide an invaluable service to the community, and it had recommended that the Ministry of Health should be urged to encourage local authorities to establish a service along the lines of the district nursing service.

The G.M.S. Committee agreed that the matter should be raised again with the Ministry, with the support of the Public Health Committee.

Rent and Rates

The Committee's attention was drawn to the following letter from the Ministry of Health about the two months' time limit for making representations against apportionments of gross value under the provisions of paragraph 34 of E.C.N. 569 (*Direct Payments for Rent and Rates*):

As agreed during negotiation this paragraph provides that representations to the Minister must be made within two months of the date of the [executive] council's final decision. In apportionment cases the doctor is of course in a position to appeal against the apportionment shortly after learning what the apportionment is, but it can well be argued that the date on which the council notifies the doctor about the payment he will receive under the scheme—that is, the amount that will have been calculated by reference to the apportioned figure multiplied by the factor—is the relevant date for the purpose of appeal. We have let it be known, therefore, that we would not refuse to consider any representations made within this limitation. This is not of course quite the same as your correspondent mentions, as in our view the actual date of announcement of the factor to the profession as a whole has no relevance in this context and there may have been some slight misinterpretation of words.

We think it reasonable to allow the above interpretation of paragraph 34, as to many doctors the apportionment itself without knowledge of the factor is not a meaningful figure, particularly when there is a preconceived idea of what an acceptable payment would be. It must be clearly understood, however, that any representations deferred until the amount of payment is known can still only be made against the apportionment itself. There is no individual appeal against the

factor which will be a negotiated figure common to all.

Mental Health Service

The Committee considered a letter from the Ministry of Health about a proposal to have an emergency mental health service admission bureau for Greater London. It stated that the Ministry still took the view that a catchment area system for admission was best, with its advantages of full integration of admission, care, and aftercare. When there was difficulty the Ministry was confident that the solution was to be found in the better use of existing resources on a catchment area basis rather than by setting up a further organization. From the evidence the Ministry had available it thought that the difficulties of finding a bed for cases needing hospital admission were far from being general, and it was proceeding with its review of emergency admission arrangements, and was concentrating on one or two areas where clarification of admission procedures might improve the service.

Dr. D. R. COOK said that this was completely unsatisfactory. The Committee must insist on either an emergency bed bureau or areas of district responsibility, so that the hospital concerned had to accept final responsibility for finding a bed for an emergency case.

The Committee agreed to continue to press the Ministry on this matter.

Heroin Addicts

The Committee discussed a memorandum from the Ministry on the rehabilitation and aftercare of heroin addicts.

The CHAIRMAN drew attention to the following paragraph headed, "The Provision of General Medical Services," which related particularly to general practitioners: "In all cases of discharge from hospital there should be full consultation with the general practitioner well in advance of discharge, and he should be notified in the usual way immediately a patient leaves hospital. Many of these patients, however, will have had no family doctor, and in such instances the executive council for the area to which the patient is to be discharged should be notified well in advance, so that, in consultation with the local medical committee, they may help the patient and/or his relatives to find a doctor who will undertake to be responsible for the patient's general medical care."

The Chairman pointed out that the Committee had previously considered the *Second Report of the Interdepartmental Committee on Drug Addiction (B.M.J., 27 November 1965, p. 1259)*, and one of its recommendations was that there should be powers of compulsory detention. The Government had not sought that power in the Act, largely as a result of medical opinion. The intention was that registered addicts could obtain their supplies only from certain centres, and it would be an offence for a general practitioner to treat a registered addict. In his opinion that was an impairment of the professional freedom of the doctor.

Dr. RIDGE pointed out that it was the Minister's duty to carry out the Act. The memorandum was concerned almost exclusively with hospital arrangements, and it

was not the G.M.S. Committee's business to comment on the proposed administrative arrangements within the hospital field. It would be wiser to limit observations to the paragraph, quoted by the Chairman, on the provision of general medical services.

Dr. A. ELLIOTT asked what a general practitioner was to do when an addict came to his surgery, perhaps in the middle of the night. The facilities envisaged in the Act to cover such an emergency did not yet exist. Dr. SPEAKMAN asked what would happen if an addict who was allocated to a doctor got hold of heroin: would the doctor have to appear before the service committee? What protection was there for the doctor?

The CHAIRMAN replied that it was the duty of a doctor who came across a heroin addict to notify the case, and when the patient was registered as an addict he would be able to get his supplies only through a centre. So long as the doctor acted in good faith in the interests of the patient, the Chairman said he did not think the doctor would be in breach of his terms of service.

Dr. COOK said he was surprised that there was so much anxiety about the proposals. At present doctors were faced with the appalling situation where a drug addict could be allocated to them and they had the inescapable responsibility of providing general medical care for an impossible case. Under the new Act general practitioners would be relieved of the responsibility of providing heroin for addicts, and that should be an unqualified blessing for the doctor.

Dr. T. J. CARTER referred to a passage in the paragraph mentioned by the Chairman which stated that the executive council in consultation with the local medical committee might help the patient and/or his relatives

to find a doctor who would undertake to be responsible for the patient's general medical care. Dr. Carter hoped that the Committee might suggest that the allocation scheme should not be used in these circumstances.

Dr. J. L. MCCALLUM pointed out that if an addict were allocated to a doctor the doctor would still have a primary duty to the addict as a patient, and he could not escape that by quoting an Act of Parliament; he must treat the patient if he came to the surgery.

Dr. RIDGE said that the point made by Dr. Carter was the reason for the wording of this paragraph. But the Minister was not prepared to write to executive councils to the effect that in no circumstances would patients discharged from hospital after treatment for heroin addiction ever be assigned to a doctor. Dr. Ridge proposed that no exception should be taken to the wording of the paragraph of the circular.

Dr. WELLS said that that was not the only paragraph which concerned general practitioners. There were paragraphs on the placement of drug addicts in families and the provision of hostels. The care of addicts living in hostels or with families would fall on general practitioners. It was obvious that such people would have to be allocated, because they would not be generally acceptable.

Lack of Facilities

Dr. D. L. WILLIAMS said that this was a "typical Ministry paper scheme," putting forward proposals which could not be implemented owing to lack of facilities. It was up to doctors to produce evidence for the

Minister that these facilities were non-existent, particularly in London.

Dr. I. M. JONES hoped that the Committee would reject Dr. Ridge's proposition. He thought it was a mistake to consider a document, take one paragraph of it completely out of context and pronounce upon it, and to ignore all the other paragraphs. If an addict came to a doctor's surgery the doctor had an ethical obligation to do what he could for him. The Minister was placing doctors in a position in which they might be unable, without breaking the law, to do what was necessary for the patient. Doctors should not acquiesce in an arrangement of that kind. The Minister had made regulations which he must have known he was in no position to fulfil. The result was that a doctor could have a drug addict allocated to him, he could be compelled to accept that patient, and yet he would be unable, owing to an Act of Parliament, to provide him with what he needed. The acceptance of this document would lessen the freedom of the profession, and would go against its ethical and moral principles.

Dr. W. HEDGCOCK, Secretary to the Committee, pointed out that a general practitioner could prescribe heroin in an emergency.

The Committee decided that the Minister should be informed that his proposals were premature. Grave disquiet had been expressed by the members of the Committee who were acquainted with the problem. When it was possible, with the help of the local executive council and local medical committee, to find a doctor who was willing to undertake the responsibility for an addict's general care that would be acceptable, but the Committee considered that to use the allocation procedure would be inappropriate.

General Medical Services Committee (Scotland)

The General Medical Services Committee (Scotland) met in Edinburgh on 21 September. Dr. ALISTAIR CLARK was in the Chair.

The CHAIRMAN welcomed two new representatives from the Glasgow Local Medical Committee, Dr. J. McGlone and Dr. J. S. Scobbie.

The Committee discussed the method of appointment of the two Scottish representatives on the Assistants and Young Practitioners' Subcommittee of the G.M.S. Committee. Though it had been customary for the G.M.S. Committee (Scotland) to nominate one assistant and one young practitioner to the Subcommittee (at the same time coopting them to the G.M.S. Committee (Scotland)), that procedure was now considered insufficient.

The Committee resolved that in future local medical committees should be asked to submit nominations, and that from these the G.M.S. Committee (Scotland) should choose one assistant and one general practitioner to serve on the Assistants and Young Practitioners' Subcommittee.

General Practitioners in Hospitals

Dr. C. J. SWANSON reported that a meeting of the working party, of which he was chairman, had considered the remuneration

attached to 10(a)* hospital appointments. The working party thought that the increase in the "bed fund" had been unrealistic and that it should be reassessed. The Secretary was collecting data from cottage hospitals on the numbers of 10(a) beds and the amount paid per doctor out of the "bed fund" over the past year.

Also, said Dr. Swanson, the working party had been concerned with the position of general practitioners who undertook more specialized clinical responsibilities under 10(b) appointments—for example, in anaesthetics. The working party thought that in such situations responsibility pay should be added which would recompense those doctors for their special skill and experience. It was also important that there should be security of tenure for such appointments. Dr. Swanson said that it was hoped that an early meeting could be arranged with the Scottish

* General practitioners employed part-time in hospitals are paid in one of two ways. In one they are paid from a staff fund at the rate of £40 a year per bed occupied (10(a) appointments), and in the other they are paid at the rate of £275 a year for each weekly notional half-day up to a maximum of £2,475 a year (10(b) appointments). The staff fund (10(a)) method of payment applies to work in general-practitioner hospital units, and the sessional method (10(b)) to work in convalescent homes, general-practitioner maternity hospitals, and other types of hospital where no other rate is appropriate.

Home and Health Department to make representations on this subject.

Matters for Department

The Stirling and Clackmannan Local Medical Committee reported a case of a doctor who, at the request of the police, had hurried many miles to a casualty only to find that the patient had been removed to hospital.

That circumstance was not uncommon, it was stated, and the Committee thought that doctors should be entitled to some payment. It decided to discuss the matter with the Scottish Home and Health Department.

Previously suggestions had been made by the Committee for a pad which would incorporate claim forms for (1) attendance on a temporary resident, (2) emergency treatment, and (3) a night visit. It had been agreed that the matter should be discussed further with the Scottish Home and Health Department.

Dr. W. B. PRESTON urged that this multi-purpose claim form should also include a form for treating dental haemorrhage.

Maternity Services

The Committee debated whether the Maternity Services Committee of the Scottish

Council was the appropriate body to consider general-practitioner maternity service fees. Though that Committee had a number of general practitioners among its members it seemed wrong that consultants and public health medical officers should be involved in questions of general-practitioner pay.

Dr. W. W. FULTON proposed that the G.M.S. Committee (Scotland) should appoint a Maternity Services Subcommittee to consider matters affecting remuneration, and that the Maternity Services Committee of the Scottish Council should continue to discuss clinical matters. Dr. SWANSON, however, thought that the Maternity Services Committee of the Scottish Council was competent to cover all aspects of the maternity services, and that it was advantageous to have representatives of other branches of the profession on the Committee.

Dr. Fulton's motion was seconded by Dr. W. M. WILSON, and it was resolved that a Maternity Services Subcommittee of the G.M.S. Committee (Scotland) should be appointed and that its membership should be the Chairman and Vice-Chairman (*ex officio*), Dr. J. McGlone, and the G.M.S. (Scotland) members of the Maternity Services Committee of the Scottish Council.

A memorandum from the Fife Local Medical Committee was considered which described arrangements between that committee and the medical staff of the Forth and Craigtoun hospitals for a shared maternity service.

Dr. JOAN K. SUTHERLAND suggested that this document might be available to the Maternity Services Committee of the Scottish Council. Dr. MCGLONE disagreed with Dr. Sutherland. He thought that the subject should be discussed first by the new Maternity Services Subcommittee.

The Committee agreed with Dr. McGlone.

Birsay Report

Dr. SWANSON, Chairman of the Highlands and Islands Practitioners' Subcommittee, informed the Committee that the subcommittee was examining the Report of the "Birsay Committee" on General Medical Services in the Highlands and Islands (*Supplement*, 8 July, p. 23). Its views would be presented to the next meeting of the G.M.S. Committee (Scotland) on 7 November.

Dispensing Doctors

It was reported to the Committee that the Rural Practitioners Subcommittee, at a recent meeting, had resolved that it be recommended to the G.M.S. Committee (Scotland) (a) that a small *ad hoc* subcommittee should be appointed to examine the position of dispensing doctors, and thereafter to meet the Scottish Home and Health Department for an exploratory discussion, and (b) that the members of the *ad hoc* subcommittee should be Drs. C. J. Swanson, H. B. Muir, P. A. P. Mackenzie, J. L. T. Dickie, and C. S. Sandeman.

The Committee agreed that the time was appropriate to consider the overall "dispensing situation" in Scotland, and that arrangements should be made for discussions with the Scottish Home and Health Department.

Vaccination and Immunization Fees

The Committee received a letter from the Scottish Home and Health Department about a review of immunizations scheduled as being on the ground of public policy and their evaluation by a Joint Working Party of the English and Scottish Health Services Councils. The draft revised schedule was before the Committee.

Dr. C. D. FALCONER, Assistant Scottish Secretary, read a letter from Dr. H. B. Muir which pointed out that a changeover from the existing schedule would necessarily take some time, since patients who had already been instructed to bring their children at 18 months would continue to do so for another 12 months. General practitioners carrying out these immunizations should be paid under the current schedule of fees.

Dr. S. PEACE suggested that a reference should be made in the revised schedule to measles immunization. Dr. E. V. KUENSSBERG said that the Medical Research Council was undertaking a national study on this and it would be advisable to await the result.

The Committee agreed that approval should be given to the draft revised schedule.

Open Access to Diagnostic Facilities

Dr. C. D. FALCONER reported that a second survey of diagnostic facilities open to general practitioners in Scotland had been carried out. It had shown little substantial change in circumstances since the previous inquiry three years ago, and that in fact the facilities available in Scotland were considerable.

Dr. PRESTON pointed out that access to x-ray facilities were inadequate in Fife, and the Fife Local Medical Committee was anxious to have the matter raised with the Scottish Home and Health Department. Dr. J. S. GARDINER reported a similar situation in Stirling and Clackmannan where practitioners had been informed that x-ray facilities would cease forthwith. General practitioners had been annoyed at the abruptness of the closure without any prior consultation with the doctors in the area.

University and Armed Forces Pay for Prices and Incomes Board

The National Board for Prices and Incomes has been instructed to keep under continuous review the pay of university academic staff and pay and allowances in the armed Forces. The order came into force on 1 November, and was made by the Government under Section 3 of the Prices and Incomes Act, 1966. The board will report on the subject matter of the standing references from time to time or when asked to do so by the Ministers concerned. Standing references can be varied by Ministers or withdrawn at any time.

In the past the pay of preclinical medical teachers has been settled at the same time as other university academic staff. The pay of clinical medical teachers has been fixed separately, and it has been customary for it to be related to the Review Body's awards to hospital doctors in the N.H.S. At a meet-

The Committee agreed to make representations on behalf of these two areas to the Scottish Home and Health Department.

Draft Memoranda

The Committee considered a circular to executive councils from the Scottish Home and Health Department concerning additional payments to women doctors during absence owing to pregnancy and child birth.

Dr. JOAN SUTHERLAND complained that the scheme appeared to exclude all women who were in a group or partnership, when it was assumed that their colleagues would take on the extra work without payment. She thought that the payment should be available to all married women doctors in general practice.

The Committee did not support Dr. Sutherland's view, and it was resolved to accept the draft document.

The Committee also considered another draft executive council circular concerned with the modifications in the interpretation of the remuneration arrangements for designated areas, group practice, seniority, and vocational training. The Committee was not satisfied about the position of single-handed rural practitioners, and it objected strongly to the suggestion in the document that a group of single-handed doctors could manage to operate from a common surgery.

Dangers of Tranquillizers

Dr. W. M. PATTERSON complained that the pamphlet on the dangers of tranquillizing drugs which had been sent recently to all doctors by the Committee on Safety of Drugs (the Dunlop Committee) had been quoted in the public press. This had caused much distress to patients, who were the very people who should not have access to this type of news.

The Committee agreed to write to the Medical Assessor of the Dunlop Committee to ask that in future every care should be taken to see that the Dunlop Committee's communiqués reached only the medical profession.

ing with representatives of the B.M.A. in November 1966 the Minister of State for Education and Science, Mr. Goronwy Roberts, stated that in the event of university teachers' pay being referred to the Prices and Incomes Board the B.M.A. would be able to give evidence on medical pay directly to the board.

Since 1962 the pay of doctors in the armed Forces has been fixed separately from other branches of the Forces, and has customarily been related to the Review Body's awards. Currently negotiations between the B.M.A. and the Minister of Defence on the B.M.A.'s pay-claim for doctors in the armed Forces have broken down, and the Association has refused to accept advertisements for medical posts in the three Services, and has advised deans of medical schools of the situation.

S.H.M.O.s Group Council

A meeting of the Association's Senior Hospital Medical Officers Group Council was held on 26 October. Dr. N. STRANG was re-elected Chairman and Dr. L. E. BURKEMAN Deputy Chairman.

Dr. E. GREY-TURNER, Deputy Secretary, said that the old Group Council had been summoned, though its constitution was about to be changed, and that it was proposed that it should be replaced by a new and smaller Group Committee. The Council of the Association had approved that proposal on 25 October, so there had been no option but to summon the old Group Council.

The CHAIRMAN said that consideration had to be given to the method of electing representatives to the new committee.

S.H.M.O.s in Declining Specialties

Dr. N. V. WILLIAMS reminded the Group Council that it had suggested at its last meeting that the following paragraph should be included in the hospital doctors' "charter": "The Government should provide facilities for the rehabilitation of S.H.M.O.s in declining specialties." Dr. Williams asked what was happening to S.H.M.O.s in that position.

Dr. GREY-TURNER said that he knew of two S.H.M.O.s who were considering taking junior appointments in other specialties in order to retrain, but he did not know whether either of them had yet come to a definite decision.

The CHAIRMAN asked if it was possible for an S.H.M.O. to take a junior appointment and retain his terms and conditions of service as an S.H.M.O. on a personal basis. Dr. GREY-TURNER said that he had consulted the Ministry of Health about paragraph 97 of the Review Body's seventh report, which had recommended that when a doctor took an appointment in a lower grade for approved training purposes he should continue to receive the salary he was getting in his last appointment in the higher grade. He had asked the Ministry whether this paragraph applied to an S.H.M.O., and the Ministry had said that it did, provided that the acceptance by a senior hospital medical officer of a more junior appointment was a move which was regarded by the hospital authority as legitimate and sensible for retraining purposes.

In reply to Dr. WILLIAMS, Dr. GREY-TURNER said that an S.H.M.O. on completing his retraining would have to apply for a post in the new specialty, but he would take with him to the new post, as a residual S.H.M.O., his existing terms and conditions of service which he held on a personal basis.

The CHAIRMAN suggested that the matter might go to the Negotiating Subcommittee of the Central Committee for Hospital Medical Services.

The Group Council agreed to put forward a recommendation that "S.H.M.O.s who wish to go into another specialty should have an opportunity for a period of rehabilitation without any personal loss to themselves."

its last meeting had been incorporated in the "charter." Dr. GREY-TURNER said that the charter, published in the Annual Report of Council in May (*Supplement*, 13 May, p. 93) had stated in general terms that S.H.M.O.s should retain their personal terms of service in all circumstances, but it had not specifically said (a) that residual S.H.M.O. posts should be designated as supplementary consultant posts; (b) that S.H.M.O.s should have the unrestricted right to undertake domiciliary consultations; and (c) that S.H.M.O.s should have the option to be whole-time or maximum part-time, like consultants, which were the points to which Dr. Meir had referred.

The CHAIRMAN said that his regional hospital board took the view that domiciliary consultations should be done by consultants, but, if there were too few, S.H.M.O.s should also be allowed to do them. His board also thought it had the right to decide whether a post should be part- or full-time.

Dr. GREY-TURNER said that domiciliary consultations were supposed to be done only by consultants. The only exception was when there were not enough consultants to meet the demand. Then it had been open to a board to allow selected S.H.M.O.s to do these consultations. Before the publication of H.M.(64)94 (a Ministry circular in 1964 entitled "Medical Staffing Structure in the Hospital Service") regional boards could say which S.H.M.O.s might do domiciliary consultations. After the issue of the circular any S.H.M.O. who had previously been allowed to do domiciliary consultations could continue to do so.

Dr. MEIR moved: "That S.H.M.O.s, being members of the senior hospital medical staff, should be allowed to do domiciliary consultations."

The motion was lost.

Mr. G. WARING ROBINSON referred again to the point that residual S.H.M.O. posts should be designated as supplementary consultant posts. He asked that unless that suggestion had been rejected by the Ministry it should be reconsidered. The CHAIRMAN said that it had been rejected, but that did not mean the matter could not be raised again. Dr. V. M. HAWTHORNE suggested that fresh evidence would be needed if there was to be any chance of success.

Dr. MEIR suggested that the question of S.H.M.O.s being given the option of whole- or part-time appointments should be further investigated.

The CHAIRMAN said it had been proposed that the difference between part- and full-time consultants should be abolished and an ordinary contract should be one of ten-tenths, with the right to do private work. So far this recommendation had not been accepted.

After further discussion it was proposed: "That when consultant sessions become available they should first be offered to part-time S.H.M.O.s in the relevant specialty in the region."

The motion was seconded and carried.

Group Committee and the question of co-option had to be considered. The new constitution provided that "the new Committee will consist of 18 members—one from each region in England and Wales, two from Scotland, and one from N. Ireland." This had been discussed, and the opinion had been that the best way of electing representatives would be on a regional basis, perhaps by postal vote.

Dr. GREY-TURNER said that either nominations from each region could be asked for—and if more than one name was received an election could be held in that region—or a regional convener could be appointed who would convene a meeting at which a representative to the Committee would be elected.

It was decided to implement the second suggestion. The Group Council then proceeded to elect representatives from each region to act as a convener.

The new constitution also allowed that the new Group Committee would have power to co-opt not more than two additional members, and it was provisionally agreed that Dr. W. Griffel and Dr. V. M. Hawthorne should be co-opted.

The Committee agreed that the election of a representative to the Central Committee for Hospital Medical Services should be deferred until the first meeting of the new committee, but if the C.C.H.M.S. met in the meantime it was agreed that Dr. Strang should attend.

Other Matters

The CHAIRMAN said that evidence to be sent to the Review Body on behalf of S.H.M.O.s had been collated, and he had been invited to attend a meeting of the Negotiating Subcommittee of the Central Committee for Hospital Medical Services in July.

Dr. WILLIAMS asked what was the composition of the Negotiating Subcommittee ("Committee of Fifteen"). Dr. GREY-TURNER explained that it consisted of nine members appointed by the C.C.H.M.S., of whom six were senior staff and three were junior staff; five members appointed by the Joint Consultants Committee; and one member appointed by the Central Dental Consultants and Specialists Committee.

Mr. WARING ROBINSON asked again if it was worth while pursuing the question of supplementary consultant posts for S.H.M.O.s, and whether it was a matter which was supported by the Council of the B.M.A.

Dr. GREY-TURNER said that it had been supported by the Council in principle, but the C.C. and S. Committee (as it then was) had turned it down.

It was suggested by Dr. HAWTHORNE that information collated from a questionnaire which had been circulated to S.H.M.O.s recently might be used to make a full questionnaire or plebiscite of all doctors, or all doctors in the hospital service, as had been done in respect of merit awards. In that way it would be possible to find out what support there was among consultants for the establishment of a new grade of supplementary consultant to take in residual S.H.M.O.s.

Domiciliary Consultations

Dr. M. MEIR asked if the other points which the Group Council had discussed at

New Constitution

The CHAIRMAN said that a more detailed method of electing representatives to the

"Mediflash"

The Chief Commissioner, Metropolitan Police, deprecates the use by doctors of Mediflash, a portable, flashing green light for fixing to the roof of a doctor's car when travelling to emergencies (*Supplement*, 14 October, p. 15).

A letter to the B.M.A. states that the Commissioner has been advised that Mediflash does not infringe the law, but he deprecates its use because "any further proliferation of flashing lights is bound to detract from the effectiveness of those that are already fitted to vehicles belonging to the fire, ambulance, and police services." Moreover, he doubts whether, without an audible warning device, the light will be of any great benefit. Metropolitan police officers have been told of the existence of Mediflash and that its use confers no special privileges in relation to the law and to traffic regulations.

The Secretary of the Association has written to honorary secretaries of B.M.A. Metropolitan Divisions informing them of the Chief Commissioner's attitude, and stating that there is no reason why doctors should not use Mediflash "provided that they adhere absolutely" to the conditions laid down.

Opportunities Overseas for Retired Practitioners

A deputation from the Association's Committee on Overseas Affairs visited the Ministry of Overseas Development on 1 November to discuss a resolution of the Annual Representative Meeting 1967 that inquiries should be made into the "desirability of setting up a system whereby retired but fit doctors might give the benefit of their services for a period in the developing countries which are short of medical manpower. . . ."

The deputation consisted of Professor D. E. C. Mekie, Professor F. E. Stock, and Dr. W. Norman-Taylor, and the outcome of what was said to have been "a useful meeting" will be reported to the Committee on Overseas Affairs.

H.M. Forces

Appointments.—Group Captain R. S. Peill (anaesthetic duties, R.A.F. Hospital, Wroughton); Wing Commander F. P. Stephens (neuro-psychiatry duties, R.A.F. Hospital, Muharraq); Wing Commander F. S. Black (officer in charge of Central Medical Trade Test Board, R.A.F. Halton); Wing Commander A. H. Cox (senior medical officer, R.A.F. Locking).

REGULAR ARMY RESERVE OF OFFICERS ROYAL ARMY MEDICAL CORPS

Major J. K. Lawton, from Reserve of Officers, to be Major.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Major (Honorary Lieutenant-Colonel) G. J. H. L. Hall has resigned his commission, retaining the honorary rank of Lieutenant-Colonel.

Major B. J. Harries has resigned his commission.

Captains (Honorary Majors) O. Garrod, M.B.E., and C. J. Goodall have resigned their commissions, retaining the honorary rank of Major.

Captain (Honorary Major) W. R. Gauld, T.D., has resigned his commission.

Was it a Drug?

Regulation 16 of the National Health Service (Service Committees and Tribunal) Regulations, 1956, provides that when a practitioner prescribes under the National Health Service preparations which are not drugs or medicines, and therefore outside the scope of the Act, the executive council may recover their cost from him. If he challenges the council's action the matter may be referred to the local medical committee. Either party or the Minister can appeal to a referee or referees against the local medical committee's decision.

The referees on each occasion are appointed by the Minister of Health. They must not exceed three in number and they must not be officers of the Ministry of Health. At least one must be a general medical practitioner. In practice the number of referees appointed has usually been three. The Chairman has been a layman with legal training, and his two colleagues have been general practitioners selected from a panel chosen by the General Medical Services Committee of the B.M.A.

The findings* of the referees in some recent appeals under the regulations are reported below. The decisions in these, as in all cases, are related only to the circumstances of the particular cases and are not binding on referees who may hear other cases.

Casilan

The referees considered two cases in which Casilan had been prescribed. In each case the local medical committee, on a reference from the executive council, had decided that Casilan was a drug which the executive council was bound to provide.

In the first case Casilan had been prescribed for a patient suffering from idiopathic steatorrhoea. The reason for the local medical committee's decision had been that the patient had been advised in hospital that he should have a gluten-free diet and Casilan had been recommended. As a result his health had improved.

The medical members of the panel of referees thought that in this case Casilan should be regarded as a drug, because gluten-free flour cannot be made into bread without the addition of something to make it combine, and Casilan was useful for that purpose. The referees therefore decided that the executive council was bound to provide it in this case.

The referees were unable to support the decision of the local medical committee in the second case. Casilan had been prescribed for a patient suffering from heart failure, diabetes, blindness, and uraemia. In deciding that Casilan was a drug which the executive council should provide, the local medical committee had considered that in the circumstances the patient was likely to suffer from hypoproteinaemia and that Casilan would combat the condition.

The referees' report stated that Casilan was essentially a food consisting of concentrated protein nearly free from salt, and as such would not be one of the things executive councils were bound to provide. Traditionally, if not logically, the absence of salt had been

regarded as a medicinal property in cases where a salt-free high-protein diet was required. In the case under consideration the referees said a salt-free diet was clearly indicated, but the patient suffered from uraemia, and they had been informed that that required a low protein diet unless due to nephrosis.

The report stated that it did not appear that the doctor had at any time stated that his patient suffered from hypoproteinaemia. The referees therefore decided that in this case Casilan was not a drug which the executive council was bound to provide.

Complan

The referees were also unable to support the decision of a local medical committee that Complan was a drug which the executive council was bound to provide.

In this case Complan had been prescribed for a patient who was suffering from carcinoma and was unable to take normal food. The referees in their report stated that the patient's doctor had said that he had continued the hospital treatment when he prescribed Complan, and, in his opinion, it had kept the patient from starving. The local medical committee had considered Complan appropriate as a means of nourishment.

"All this may be true," said the referees, "but we have to apply an Act which obliges hospitals to nourish their patients while the executive councils have only to provide the medicine." The referees decided that in this case Complan was not a drug which the executive council was bound to provide.

Brandy

The referees considered a case in which brandy had been prescribed for a patient suffering from severe peripheral artery disease causing intractable ischaemic ulcers. The local medical committee, on appeal from the executive council, had decided that this was not a drug which the executive council was bound to provide.

The referees, in their report to the Minister, stated that the patient's doctor had said that he had treated the patient's malady for many years. Surgery had not helped her. In September 1966 she had become much worse, with painful and intractable ulcers on her legs. Rest in bed, various vasodilators, five systemic antibiotics, and daily dressings of Cicatrin powder and Tulle Gras had "left the problem of restoring the peripheral circulation unsolved." The doctor had then recalled the advice of a consultant in a similar case in 1963 in which brandy had been prescribed. The local medical committee at that time had decided that that brandy was properly ordered as a drug. The patient had recovered.

The doctor had stated, continued the referees' report, that with this case in mind he had ordered 1 oz. (28.4 ml.) of brandy twice a day for his patient, who had also recovered. The doctor had stated that in April this year his confidence in his argument had been shaken by an article in the *British Medical Journal*, which had said, in effect, that alcohol produced a significant degree of

* These findings are normally sent only to the interested parties. They are sent by the Ministry of Health to the *B.M.J.* with all names deleted.

vasodilatation in normal, healthy subjects but that its effects on occluded or arteriosclerotic vessels had not been shown. Nevertheless, the doctor had contended that a belief among doctors that alcohol was a useful vasodilator was sufficiently widespread to justify its prescription in a case of this sort. Asked by the referees why he had not prescribed rectified alcohol, the doctor had replied that he preferred brandy. To the suggestion that the real purpose of the prescription was to produce a state of euphoria the doctor had said that 2 oz. of brandy a day would not be enough for that.

The referees' report stated that the Minister's representative had argued that alcohol was not the proper remedy because the area of occlusion might be high up, in which case alcohol would not have been effective. The medical members of the panel of referees accepted that argument. They thought the doctor should have had regard to the Report on the Definition of Drugs which held that alcoholic beverages were not to be regarded as drugs. The third referee thought that there had been too many decisions that whisky, brandy, and gin could be regarded as drugs for the advice of the Joint Committee on the Classification of Proprietary Preparations to be taken strictly.

The referees decided that in this case brandy was not a drug which the executive council was bound to provide.

Sketofax

A case in which two tubes of Sketofax had been prescribed for a patient suffering from marked irritation of the face and body probably associated with fleas was considered by the referees. The local medical committee had decided that Sketofax was a drug which the executive council was bound to provide.

The patient had been referred to a hospital where the diagnosis of flea-bites had been confirmed, and she had been given Sketofax. The

patient's doctor had thought he was justified in repeating the treatment.

The referees reported that they were not impressed by that argument. Their report continued: "The *British National Formulary* recommends that when some of a family living together are infected with scabies all should be treated with benzyl benzoate. From this the local medical committee infer that executive councils may have to provide

preventive drugs. We agree, but for such drugs to be properly charged to the executive council there must be some probability that the patient will contract a disease. Everyone is liable to a flea-bite. There is nothing to show that this patient is more likely than anyone else to suffer another flea-bite."

The referees decided that in this case Sketofax was not a drug which the executive council was bound to provide.

B.M.A. Nuffield Library

The Library service is available to all members of the Association resident in Great Britain and Northern Ireland (and by special arrangement to members of the Irish Medical Association). A copy of the library rules will be forwarded on application to the Librarian at B.M.A. House.

The following books have been added to the Library:

Association Notices

Armed Forces Committee Nomination of Members for Co-option

The constitution of the Armed Forces Committee was amended at the Annual Representative Meeting of the Association in July 1967 to allow greater representation of serving medical officers, especially younger members, by means of co-option to the Committee. The Committee may now co-opt two representatives of the rank of major or equivalent (lieutenant-commander or squadron leader) or below, one of whom should preferably be of specialist status, from the medical branch of each of the Services.

Notices appeared in the *B.M.J. (Supplement)*, 26 August and 16 September, pp. 124 and 130 respectively) inviting serving medical officers to nominate members of the Association in the armed Forces in these ranks for co-option to the Committee.

At its meeting in October the Armed Forces Committee considered the nominations received and the following have been co-opted to the Committee:

Army.—Major T. R. Austin, specialist in anaesthetics, at the Cambridge Military Hospital, Aldershot.

Navy.—Surgeon Lieutenant-Commander J. A. M. Wright, medical specialist at the Royal Naval Hospital, Plymouth; Surgeon Lieutenant-Commander D. S. Wright, G.D.O., H.M.S. *President*.
R.A.F.—Squadron Leader J. B. Crowe, Consultant Radiologist, P.M.R.A.F. Hospital, Halton, Bucks.

The Committee thought it was most important that non-specialists should be represented from each of the Services, and it decided to seek further nominations for the non-specialist vacancy in the Army and in the R.A.F. representation.

Serving medical officers in the Army and the R.A.F. are therefore invited to nominate members of the Association in the rank of major, squadron leader, or below of non-specialist status for co-option to the Committee. It is hoped that those nominated would have a reasonable expectation of being available to attend meetings in London in the foreseeable future.

Nominations should be sent to the Secretary of the Association by 23 December 1967 for subsequent consideration by the Armed Forces Committee.

DEREK STEVENSON, *Secretary*.

Diary of Central Meetings

NOVEMBER

- 14 Tues. Standing Subcommittee (Central Ethical Committee), 11 a.m.
- 14 Tues. G.M.S. Disciplinary Machinery Working Group, 2 p.m.
- 15 Wed. Committee on the Mental Health Act, 10.30 a.m.
- 15 Wed. Executive Subcommittee (Film Committee), 2 p.m.
- 15 Wed. Rural Practices Subcommittee (G.M.S. Committee), 2 p.m.
- 15 Wed. Executive Subcommittee (Film Committee), 2 p.m.
- 15 Wed. G.M.S. Dispensing Working Group, 5 p.m.
- 16 Thurs. Chairman's Subcommittee (Organization Committee), 9.30 a.m.
- 16 Thurs. General Medical Services, 10.30 a.m.
- 16 Thurs. Film Committee, 2 p.m.
- 16 Thurs. Membership and Information Subcommittee (Organization Committee), 2 p.m.
- 17 Fri. Working Party on Postgraduate Medical Centres, 2 p.m.
- 17 Fri. Welsh Committee (at the Metropole Hotel, Llandrindod Wells, Radnorshire), 2.15 p.m.
- 21 Tues. General Purposes Committee, 10.30 a.m.
- 22 Wed. Working Party on Amphetamine Preparations (Committee on Medical Science, Education, and Research), 9.30 a.m.
- 22 Wed. Journal Committee, 10.30 a.m.
- 22 Wed. Psychological Medicine Group Committee, 2 p.m.
- 23 Thurs. Executive Subcommittee (C.C.H.M.S.), 10 a.m.
- 23 Thurs. Compensation and Superannuation Committee, 2 p.m.
- 23 Thurs. Negotiating Subcommittee (C.C.H.M.S.), 2 p.m.
- 23 Thurs. Dermatologists Group Committee, 2.30 p.m.
- 23 Thurs. Representatives of Negotiating Subcommittee (C.C.H.M.S.) and Ministry of Health, 4 p.m.

DECEMBER

- 4 Mon. Scottish Committee for Hospital Medical Services (at 7 Drumsheugh Gardens, Edinburgh), 2.15 p.m.
- 13 Wed. Journal Committee, 2 p.m.

Branch and Division Meetings to be Held

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

ALDRSHOT AND FARNHAM DIVISION.—At Queen's Hotel, Farnborough, Thursday, 16 November, 8 p.m., wine and cheese tasting. Guests are invited.●

BLACKBURN DIVISION.—At 13 Merlin Road, Sunday, 19 November, 12.15 p.m., annual general meeting.

BRIGHTON AND MID-SUSSEX DIVISION.—At Sussex Postgraduate Medical Centre, Thursday, 16 November, 8.30 p.m., jointly with B.D.A., Dr. E. M. Widdowson: "Nutrition of Children in Underdeveloped and Affluent Societies." (Preceded by dinner, 6.30 for 7 p.m.) Guests are invited.●

CITY OF DUNDEE DIVISION.—At Room 9, Queen's College Tower, Nethergate, Friday, 17 November, 8.15 p.m., B.M.A. lecture by Dr. John J. A. Reid: "Some Socio-medical Aspects of Diabetes Mellitus."

CORNWALL DIVISION.—At Headland Hotel, Newquay, Friday, 17 November, 7.30 for 8 p.m., annual dinner and dance. Guests are invited.●

CROYDON DIVISION.—At Medical Centre, Mayday Hospital, Tuesday, 14 November, 8.30 p.m., Mr. J. E. H. Pendower: "Surgical Aspects of Peptic Ulceration and Gastric Carcinoma."

DUMFRIES AND GALLOWAY DIVISION.—At Cairndale Hotel, Dumfries, Thursday, 16 November, annual dinner dance.

DURHAM DIVISION.—At Ramside Hall, Thursday, 16 November, 8 for 8.30 p.m., dance.●

ENFIELD AND POTTERS BAR DIVISION.—At Academic Centre, Chase Farm Hospital, Thursday, 16 November, 8.30 p.m., meeting to elect representative to Representative Body, and talk by Dr. J. Menon: "Eyes for Every Man—Fact and Fiction."

GLASGOW DIVISION.—Tuesday, 14 November, visit to Ravenscraig Steel Works, Motherwell. Transport will leave Glasgow Regional Office at 5.30 p.m.●

HASTINGS DIVISION.—At Outpatient Department, Royal East Sussex Hospital, Tuesday, 14 November, 8.15 p.m., clinical meeting. Followed by discussion of cases in Board Room (preceded by report on Annual Representative Meeting).

HENDON DIVISION.—At Hendon Hall Hotel, Tuesday, 14 November, 8.45 p.m., medical films: "Congenital Heart Defects in Young Children"; "Pulmonary Function."●

HEREFORD DIVISION.—At Board Room, Hereford County Hospital, Wednesday, 15 November, 8.15 p.m., meeting to receive report on Annual Representative Meeting, Bristol, and to elect representatives for 1968-9.

KETTERING DIVISION.—At Postgraduate Centre, Kettering General Hospital, Tuesday, 14 November, 8.30 p.m., film by Dr. A. N. Exton-Smith: "Accidental Hypothermia in the Elderly." (Preceded by buffet supper, 8 p.m.) Guests are invited.

KINGSTON-UPON-THAMES DIVISION.—At Kingston Medical Centre, Tuesday, 14 November, 8.30 p.m., Dr. A. J. Thomas: "Cholesterol in Atherosclerosis."

MID-GLAMORGAN DIVISION.—At Seabank Hotel, Porthcawl, Friday, 17 November, 7 for 7.30 p.m., annual dinner dance.

MONMOUTHSHIRE DIVISION.—At Friars Pavilion, Royal Gwent Hospital, Newport, Thursday, 16 November, 7.30 for 7.45 p.m., B.M.A. lecture by Mr. T. H. L. Rosser: "Investigation and Treatment of some Congenital Cardiac Abnormalities."

NORTHAMPTON DIVISION.—At Board Room, Northampton General Hospital, Friday, 17 November, 8 for 8.20 p.m., the Branch president will present the Scroll of Fellowship to Mr. E. E. T. Taylor; 8.30 p.m., B.M.A. lecture by Dr. W. W. Sargent: "Brainwashing" (illustrated).

NORTH-EAST ULSTER DIVISION.—At Nurses' Home, Route Hospital, Ballymoney, Tuesday, 14 November, 8.30 p.m., Dr. A. C. Glendinning: "X-ray Examinations in Pregnancy."

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle upon Tyne, Thursday, 16 November, 7 for 7.30 p.m., lecture by Mr. C. J. Dewhurst.

NORTH STAFFS DIVISION.—At Medical Institute, Hartshill, Wednesday, 15 November, 8.15 p.m., Mr. K. Baker: "Psychiatric Problems in Gynaecology."

PRESTON DIVISION.—At Sharoe Green Hospital, Fulwood, Tuesday, 14 November, 8.30 p.m., B.M.A. lecture by Professor T. N. A. Jeffcoate: "Frequency and Urgency of Micturition in the Female."

READING DIVISION.—At Library, Royal Berkshire Hospital, Friday, 17 November, 8.30 p.m., meeting to consider election of representatives to Annual Representative Meeting followed by Mr. N. G. Rothnie: "Management of Arterial Insufficiency of the Leg" (illustrated).

REDBRIDGE AND STRATFORD DIVISION.—At Whipps Cross Hospital Medical Centre, Wednesday, 15 November, 8 p.m., buffet, Dr. T. Gardiner will speak on "Effect on Medicine in this Country resulting from Entry into the Common Market." Ladies are invited.

REIGATE DIVISION.—At Burford Bridge Hotel, Friday, 17 November, 7.30 p.m., annual dinner dance.●

SOUTHAMPTON DIVISION.—At Postgraduate Medical Centre, Wednesday, 15 November, 8 for 8.30 p.m., B.M.A. lecture by Mr. G. Qvist: "The Acute Abdomen."

SOUTH-EAST ESSEX DIVISION.—At Board Room, Southend General Hospital, Wednesday, 15 November, 8.30 p.m., B.M.A. lecture by Dr. M. O'Donnell: "Looking Sideways at Medical Journalists." Guests are invited.

STIRLING BRANCH.—At Falkirk and District Royal Infirmary, Thursday, 16 November, 8.30 p.m., jointly with Falkirk Medical Society, Professor A. Goldberg: "Anaemia."

SUTTON COLDFIELD, LICHFIELD, AND TAMWORTH DIVISION.—At Lecture Hall, Postgraduate Medical Institute, Good Hope Hospital, Thursday, 16 November, 8.30 p.m., Professor A. G. W. Whitfield: "The Connective Tissue Disorders."

SUTTON DIVISION.—At Downs Club, Sutton General Hospital, Tuesday, 14 November, 8.30 p.m., Dr. R. A. Zeitlin: "Modern Aspects of Blood Transfusion." Guests are invited.

TUNBRIDGE WELLS DIVISION.—At Elizabethan Barn, Tuesday, 14 November, 7.30 for 8 p.m., jointly with Law Society, dinner meeting, Dr. J. Dunwoody, M.P., Mr. D. Fraser: "The Proposed New Abortion Laws."

WEST BROMWICH AND SMETHWICK DIVISION.—At Sandwell Hotel, West Bromwich, Wednesday, 15 November, 8.15 for 8.30 p.m., annual general meeting. (Preceded by supper.●)

WEST SUSSEX DIVISION.—At Burlington Hotel, Worthing, Wednesday, 15 November, 7 for 7.30 p.m., dinner meeting, Professor J. A. Stallworthy: "Abortion and the Law."

WIGTOWNSHIRE DIVISION.—At King's Arms Hotel, Glenluce, Monday, 13 November, 7.30 p.m., Dr. T. S. R. Train: "Recent Advances in Obstetrics and Gynaecology."

HOSPITAL JUNIOR STAFFS GROUP: SOUTH-WEST METROPOLITAN REGION.—At B.M.A. House, London W.C., Tuesday, 14 November, 8 p.m., general meeting to re-establish H.J.S. Group and to elect officers.

Branch and Division Officers Elected

BELFAST DIVISION.—Chairman, Dr. P. Steen. Vice-chairman, Dr. D. L. W. Chapman. Honorary Secretary, Dr. Charlotte C. Arnold. Assistant Honorary Secretary, Dr. H. W. Dunn. Honorary Treasurer, Dr. G. T. C. Hamilton.

EAST SUFFOLK DIVISION.—Chairman, Dr. R. Wilton. Vice-chairman, Dr. J. P. R. Richardson. Honorary Secretary, Dr. F. O. Wells. Honorary Treasurer, Dr. R. A. Leader.

LONDONDERRY DIVISION.—Chairman, Dr. R. Haire. Chairman-elect, Dr. F. C. Calvert. Vice-chairman, Dr. J. J. Cosgrove. Honorary Secretary, Dr. M. D. L. Eakin. Honorary Treasurer, Lieutenant-Colonel D. G. C. Whyte.

NORTH-EAST ESSEX DIVISION.—Chairman, Dr. D. A. Lamont. Vice-chairman, Dr. D. A. Logan. Honorary Secretary and Treasurer, Dr. P. Snell.

Meetings of Branches and Divisions

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—The annual meeting of the Branch was held on 21 September at Ysgyborwen Country Club, Aberdare. The new President, Dr. J. L. Ryce, was installed in office, and he gave an address on the development of medicine in Wales.

Correction

Dr. W. E. Dornan is chairman of the Medical Practices Committee and not Dr. A. N. Mathias, as stated in the report of the Proceedings of Council (*Supplement*, 4 November, p. 29).

Assistants and Young Practitioners Subcommittee

Younger general practitioners in their representative subcommittee discussed the implications to British medical practice if Britain joined the Common Market. They also gave their views on the place of general practitioners in district general hospitals. They thought that general practitioners should have beds in these hospitals for cases they were competent to treat. A survey among young general practitioners had shown an enthusiasm for having hospital beds. Older doctors had shown little interest.

A meeting of the Assistants and Young Practitioners Subcommittee of the General Medical Services Committee was held on 3 November. Dr. M. A. WILSON was re-elected to the chair.

The Chairman and Dr. D. F. Rickards were elected to represent the Subcommittee on the General Medical Services Committee.

Further consideration was given to a draft of a model assistantship agreement. It was reported that the G.M.S. Committee had not accepted the Subcommittee's view that an assistant who was in breach of his contract should still be entitled to any holiday period or payment in lieu of holiday that was due to him. The G.M.S. Committee, however, had agreed that provision should be made in the model agreement "to entitle the assistant to two weeks' sick leave at half-pay in addition to the two weeks at full-pay."

European Economic Community

At its last meeting the Subcommittee had decided that a memorandum setting out details of medical practice in the six countries of the European Economic Community should be referred to the Subcommittee's forward planning group. Dr. G. H. Curtis Jenkins, a member of the group, had agreed to prepare a report on the changes which had taken place in medical practice in the Common Market countries since 1963, and the effects on medical practice in this country if Britain joined the Common Market. These papers were before the Subcommittee for its consideration.

Dr. JENKINS explained that the European Economic Commission was the executive body which made proposals to the Council of Ministers, and when health matters were discussed the Ministers of Health for the various countries would attend council meetings. The Council of Ministers was empowered to make and implement decisions without necessarily obtaining the assent of the national Governments and Parliaments. Ideally the Common Market was a supranational organization.

Britain, Dr. Jenkins said, was the only country in Europe which had an organization like the General Medical Council, which was independent of Government. To other countries in Europe that independence seemed irrational. The Civil Service in the Common Market Countries had a far greater responsibility for the day-to-day running of their countries than the British Civil Service had in Britain. The Ministerial decisions in Europe were less important than those of the civil servants.

Dr. Jenkins believed that few doctors would want to come from Europe to work in Britain. Those to whom he had spoken could not understand how a "free-at-the-time" service could be made

to work, or how it was possible to practise good medicine on demand with no barrier between the patient and the doctor. Some doctors might come for training in hospitals, but he did not think that any, or only a few, would come into general practice.

Hurdles to Overcome

Dr. P. R. SMITH asked to what extent Commonwealth doctors were likely to go to Europe to practise rather than to Britain. Dr. JENKINS said he believed that there were considerable hurdles of language and "approach" for Commonwealth doctors to overcome if they wished to practise in Europe. Even those Commonwealth doctors whose mother tongue was not English were taught medicine in English and were therefore more likely to come to Britain than to Europe.

In reply to a question about the General Medical Council, Dr. Jenkins said that the duties laid down for the Council could not be altered without legislation.

Dr. J. M. DUNLOP commented on the fact that decisions were made by the Council of Ministers on a supranational basis. "Was that on a majority basis?" he asked. "Would a Minister of Health who was opposed to a decision have to agree to a majority opinion?" Dr. JENKINS said that up to now every decision had been unanimous. A use of the veto could prevent decisions being taken at all.

Dr. DUNLOP said that doctors from a country where there was an excess of doctors might come to Britain despite its Health Service.

Dr. A. W. MACARA pointed out that though no other country had followed Britain completely in a free-at-the-time service most countries had advanced varying distances along the road towards subsidized medicine. The reason why they had not gone so far as Britain was an economic one rather than a functional one—they were afraid of the cost. In fact their services cost as much if not more than the British service. So long as there was adequate control over standards Britain should welcome doctors from Europe.

Dr. JUDITH ATKINSON wondered whether the National Health Service might break down as Britain came into contact with other systems, and whether the British system might eventually come into line with the European health schemes. Dr. JENKINS said it was not a matter of Britain coming into line. It was not standardization which was wanted but harmonization.

Dr. MACARA, commenting on the British public health service, said that the statutory requirement that a medical officer of health should have a diploma in public health, and the fact that he could not be dismissed without the agreement of the Minister of Health, had given the medical officer of health status and security. Was the public health service likely to risk the loss of these privileges if Britain entered the Common Market?

Dr. JENKINS replied that a subcommittee of the European Economic Community had examined the contractual rights, pensionable rights, and ethical status of public health medical officers in Europe, and those doctors, said Dr. Jenkins, would become a powerful body.

The CHAIRMAN believed that the B.M.A. should continue to send observers to the meetings of the medical profession in the European Economic Community. This was important, because if agreement was reached on the main issues, and if Britain did not enter the Community for several years, this country would have to accept the agreements as they then existed.

Charges for Services

The Subcommittee discussed the Council's recommendation that "All Association committees should be invited to consider the question of charges for services, if any, in their respective fields and to make recommendations."

The CHAIRMAN said that for some B.M.A. services, such as the Medical Practice Advisory Bureau, car-parking badges, or photocopying by the Nuffield Library, a charge was made to non-members and sometimes to members, and the difference between the two charges was not always substantial.

Dr. DUNLOP hoped that advice would be given free to potential members, particularly students. The CHAIRMAN said that the British Medical Students' Association usually catered for students. When a student asked the B.M.A. for information on careers in medicine it was sent without charge.

The Subcommittee agreed that in those cases where the Association charged a fee to non-members it should be a realistic one, so that a much reduced fee could be charged to members if it was necessary to charge one at all.

Dr. D. G. EMERY thought non-members should pay at least three times the fee that members paid.

District General Hospitals

The Subcommittee discussed a questionnaire received from the Central Health Services Council's committee on the functions of the district general hospital. The questionnaire had been sent to local medical committees and B.M.A. Divisions earlier in the year.

The questionnaire stated that the existing doctrine on accident and emergency services was based on the advice given by the Subcommittee of the Standing Medical Advisory Committee in 1962, that "all injured patients requiring hospital treatment should be taken direct to accident and emergency units staffed and equipped to deal immediately with major injuries, and other emergency cases at any hour of the day or night."

Dr. EMERY said that in rural areas all district hospitals should have general accident emergency services, but in large towns it might be advantageous to have several specialized accident departments. Dr. DUNLOP thought that in rural areas a long ambulance ride to hospital could be dangerous. He suggested that helicopters should be used for conveying emergency cases to hospitals from outlying areas.

Dr. JENKINS said that helicopters had

disadvantages. It would be far better to "take the hospital" to the patient in the case of an emergency or accident. That was done in Germany, where a doctor went out in a fast ambulance to the scene of an accident.

Dr. G. J. DAVIES said that in Birmingham a district general hospital had been built with lavish new emergency and accident departments, but it had been difficult to obtain staff. Therefore the city had been zoned into areas, and the patient had to be taken to the hospital in the zone where the accident happened.

Dr. G. T. WALKER, representing the Hospital Junior Staffs Group, agreed that in large areas of population it would be better to have a central accident department which was well staffed and well equipped, rather than three or four inadequately equipped units. Dr. D. F. RICKARDS believed that it was important to have a doctor of consultant status available 24 hours a day in accident and emergency departments.

The questionnaire asked to what extent provision should be made in district general hospitals for rehabilitation and for what types of patient. Dr. MACARA said that the answer depended on the definition of rehabilitation. He suggested that there should be provision for occupational therapy and for consultation between consultants, general practitioners, and social workers. More specialized physical rehabilitation units should be provided only in the bigger hospitals. The CHAIRMAN agreed that the simpler forms of treatment should be available in district hospitals and more sophisticated forms in specialist hospitals. Selected district general hospitals should include a special unit for young chronic sick patients.

Obstetrics

The questionnaire asked whether all potentially abnormal obstetric deliveries should take place in a district general hospital. Dr. DAVIES said that normal deliveries, either in hospital or at home, were carried out by midwives. He knew of a general-practitioner unit attached to a new district general hospital where the only occasions on which a general practitioner was called to see a patient was when a perineum needed repairing. That was disgraceful: a general practitioner should be allowed to do a forceps delivery in a general-practitioner maternity unit.

The Subcommittee gave its qualified agreement to the proposition in the questionnaire that all potentially abnormal deliveries should take place in the district general hospital, and it suggested that the words "or a suitably equipped obstetric unit" might be added.

On the question of the size of district general hospitals, the CHAIRMAN said he believed that they should be big enough to allow for two consultants in each major specialty.

The Subcommittee next considered what clinical facilities there should be for general practitioners in district general hospitals. The questionnaire stated that it was now generally accepted that general practitioners should have "open access" to pathology and radiology departments, and it asked: (1) "Do you consider that they should also have open access to electrocardiography, electroencephalography, or other diagnostic services?" and (2) "Do you consider that the district general hospital should include

beds in which general practitioners treat their own patients? If so, for what types of case? What should be the allocation of clinical responsibility as between the general practitioner and his consultant colleagues?"

The Subcommittee agreed that open access to departments of electrocardiography should be available to general practitioners, but it did not consider that open access to any other diagnostic service was necessary.

Dr. JENKINS said that the hospitals were now thinking in terms of "departments of medicine," with a hierarchical structure. Patients would be looked after by their own general practitioners or by general practitioners attached to the hospital who would take over the care of patients who came from distant parts. Many consultants were unaware of what general practitioners could do in a hospital, and when they found out they were only too willing to enlist their help. Dr. Jenkins thought that in future general practitioners might carry out all outpatient investigations before the patient saw a consultant. Having a few general-practitioner beds "tacked on to the end of the hospital," with little contact with consultants, had been shown to be disappointing in practice in most cases.

It had often been said that general practitioners were overworked, but, said Dr. Jenkins, those who had organized themselves had been freed of the burdens of trivia, and it was those doctors who wanted to participate actively in a hospital unit.

General-practitioner Beds

Dr. RICKARDS said that it was unrealistic for general practitioners to expect to have beds of their own. They should work more in hospitals but forget about having beds. General practitioners should be on the staff of a hospital on a part-time basis, the degree of their responsibility being decided between themselves and their next superior.

Dr. SMITH said that general practitioners were not part of the staffing hierarchy of a hospital, and should not accept a superior.

Dr. DAVIES said he would welcome the opportunity of access to hospital beds. In Nottingham, where relations between general practitioners and hospitals were good, he could get investigations on patients done first and then present them to the consultant for advice on treatment. Dr. RICKARDS agreed that the more open access to diagnostic departments available to general practitioners the less they would need hospital beds.

Dr. J. F. HUGHES said that a survey among young South Warwickshire general practitioners had shown some enthusiasm for general-practitioner hospital beds. A survey among general practitioners who had been in practice for a minimum of 15 years had shown little interest in the idea of hospital beds with consultant opinion available. There had been no support for beds without consultant opinion available.

The Subcommittee decided that general practitioners should have beds in district general hospitals for cases "which the general practitioner felt he was competent to deal with." It was thought that no decision could be come to about the allocation of clinical responsibility.

The Subcommittee agreed that its comments on the questionnaire should be submitted to the General Medical Services Committee.

Fellowship for Freedom in Medicine

Mr. DESMOND DONNELLY, Labour M.P. for Pembroke, gave an address, entitled "Can the Health Service Survive?", at the annual general meeting of the Fellowship for Freedom in Medicine at Caxton Hall, Westminster, on 4 November.

Dr. P. A. T. WOOD, chairman of the Fellowship, was in the chair.

Dr. E. C. WARNER paid a tribute to Dr. R. Hale-White, president of the Fellowship and its former chairman, who had died suddenly during the week.

Survival of N.H.S.

Mr. DONNELLY, who said he believed he was the first Labour M.P. to attend one of the Fellowship's annual gatherings, pointed out that the Government was trying to enter Europe, to deflate the economy, and to continue Government spending at the same rate as in preceding years. These were a series of conflicting objects. The largest single item in Government spending was the £6,500m. on the welfare service, of which £1,500m. went to the National Health Service. There was no reason why any Government should be exempt from that immutable law of intelligent economics that "if you spend more than you are producing or earning, and do not pay attention to the earning capacity of the country, you are going to find yourselves in a very serious condition indeed."

Mr. Donnelly contrasted the situation in the 1940s, when Beveridge and others were planning post-war social security, and the situation today. In terms of aspirations and hopes the situation 25 years ago was totally divorced from the situation now, when the average income in this country was somewhere in the region of £19 a week, and five million people took their holidays abroad every year. So far as the National Health Service was concerned, he sensed "very considerable frustrations." The medical services, including a number of specialties, were inadequate, and there was an overall feeling of disillusionment with a National Health Service that was to provide free medical attention regardless of income but solely based on the individual's need. That had turned out to be "a sad disillusionment" in its practical operation. Politicians who defended the N.H.S. as it stood were either ignorant of the true situation or they were clinging to antediluvian slogans because they lacked the guts to face up to the truth. The medical profession needed to take a look at itself, too. "Our British medical profession and its standards, once among the best in the world, have crumbled," Mr. Donnelly said.

The whole Health Service concept needed rethinking. The system as it stood today should be scrapped and something quite new put in its place. "We have got to spend much more money on our Health Service, whatever form it takes. If we were to give our medical services the same priority as in the U.S.A., where there is no National Health Service, we should need another £500m. a year immediately." Mr. Donnelly said that no British Government could face that kind of bill. There was too much taxation in this country, and people were lacking incentives to produce more simply because of the incidence of taxation.

Dignity of Choice

Mr. Donnelly maintained that the money needed could not be obtained by cutting out other expenditure, such as on the armed Forces. The money could be got only out of personal consumption. "People have got to be allowed to spend more of their own money on the services they want. . . ."

People must be given the dignity of choice. At present the public had virtually no choice and no voice. "We are just told what we should have, and I do not really think we are all that competent in Westminster to determine all the time what people should have. If we start to pay directly instead of through the gargantuan machine of taxes we shall be in a better position to insist on the kind of service we want, and much more likely not to overuse the services that are available. If you think you are not paying—but of course you are, through taxes—you tend to overuse." There was no practical way at all of providing the services that the poor people needed desperately until the principle of selectivity, or each according to his ability, each according to his needs, was introduced.

Mr. Donnelly said in conclusion: "We are following a number of conflicting objectives, and we have got to get this whole strategy straight. The key factor is: How are we going to order our welfare services to make them compatible with the needs of the people and compatible with the resources available? This is really what we have got to address our minds to in the coming years. What we need is a return to the questions that were asked twenty years ago . . . and to ask ourselves whether the answers were right. We know they were not."

Chairman's Address

Dr. WOOD took the theme of "Adventure in Medicine" for his chairman's address. What had happened in the twentieth century, he asked, which had given so much to doctors in the way of weapons to fight disease, and which yet had taken so much away from them in morale and self-respect? All were a little tired of the hackneyed phrase "the stress of modern living," but it was unfortunately true.

He believed that among the great causes of stress were the powerful trends which had developed all over the world towards uniformity and conformity. In Russia, China, and much of Europe, including Britain, egalitarianism had become the motivating force behind many of the changes in politics and social life. He believed that those pressures towards uniformity and conformity were a self-destructive element in their civilization, for they were directly opposed to the variety and diversity which was in nature. If he might put it in an evolutionary nutshell, "the more you conform the less you adapt." Much of the stress of modern life developed from the frustration of the individual who wanted to be different from the herd, who wanted to be true to himself, who wanted to be responsible for himself, and stand on his own feet.

In medicine the twin dangers of uniformity and conformity affected doctors to a greater extent than any other profession, for egalitarianism in the treatment of disease had

immense emotional appeal. Fair-minded people of all kinds rejected the idea that one person should be able to get better medical attention than another, although only a moment's logical thought would convince them that equality in diagnosis and treatment was quite impossible to achieve in practice. But there they were in an area where logic counted for nothing.

The main dangers to the doctor in the National Health Service were a great lack of variety and experiment, that nonconformity was discouraged, the individual received little stimulation or encouragement, and security had replaced adventure. Those were the very reasons why young doctors were forced to emigrate. The Fellowship believed in freedom not because it wished to escape discipline, not because it wished to encourage private practice to line doctors' pockets, but because it believed in experiment, in diversity, in encouraging the individual to develop along his own lines, and especially in preserving the spark of adventure in medicine.

Fellowship Business

Presenting the accounts and balance sheet, the honorary treasurer, Mr. C. A. JACKSON, said the Fellowship was continuing to run at a deficit. Were it not for the generous anonymous donor who had been able to maintain his subscription (of £1,000) over a large number of years the Fellowship would be in a sorry state.

The honorary secretary, Dr. J. M. ALSTON, gave an account of the Fellowship's activities during the past year.

Mr. R. S. MURLEY proposed the following resolution:

"Knowing that the future expansion of medical care in Great Britain will necessitate a massive injection of additional funds, convinced that bold experiment is vitally needed in devising supplementary and alternative sources of income for the health services, and recognizing that two important surveys of public opinion confirm that many people are prepared to make more direct personal payment for medical care, this meeting of the Fellowship for Freedom in Medicine calls for a radical reform of the National Health Service so as to ensure (1) increased personal payment at the time of service (with proper safeguards for pensioners and poorer people); (2) the promotion of greater independence at the periphery, including the encouragement of fund-raising by individual hospitals; and (3) stimulation of private medical practice by tax relief and other appropriate methods."

After a short debate the motion was carried unanimously.

Computers in Medicine

The B.M.A. and the Institute of Mathematics and its Applications are holding a symposium at B.M.A. House on 6 December on the application of mathematical and computer methods to problems in medicine. Papers will be read by Dr. Bryan Thwaites, President of the Institute of Mathematics and its Applications and Principal of Westfield College, London ("Mathematical Models in Medi-

General Practice Finance Corporation

cine"); Dr. H. R. A. Townsend, consultant neurophysiologist, Western General Hospital, Edinburgh ("Wave Forms of Biological Origin"); Professor John Anderson, King's College Hospital, London ("Problems in Medical Vocabulary"); Professor Paul Hall, Karolinska Hospital, Stockholm, Sweden ("Automated Diagnosis"); and Dr. J. Howlett, Director of the Science Research Council's Atlas Computer Laboratory ("Data Bank Problems").

There is an advance registration fee of 15s. for members of the Association or the Institute and of £2 for non-members. The fee includes a hamper lunch and tea. An additional charge of 17s. 6d. will be made to those staying on for a buffet supper. The number attending the symposium will be limited to 300.

Further particulars and registration forms are obtainable from the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London W.C.1.

Information has now been provided by the General Practice Finance Corporation on the amount of money paid out in loans for various purposes, or for which authorizations had been made, up to 20 October. The first report of the Corporation covering the first few months of its existence, from 21 November 1966 to 31 March 1967, was published on 23 October (*Supplement*, 4 November, p. 41).

Up to 20 October the Corporation had received 462 inquiries from general practitioners and had made loans totalling approximately £950,000. Authorizations for 144 loans amounting to £696,500 had been made, but three of these, totalling £5,200, had been withdrawn. Actual payments made to doctors up to 20 October had amounted to £136,000. The Corporation had also taken over outstanding applications from general practitioners to the Group Practice Loans

Scheme. These applications had been for loans amounting to £779,000, of which £136,000 had been paid out to date.

Twenty-four loans totalling £182,750 for the erection of purpose-built premises had been made, and £175,400 had been paid out in loans to enable general practitioners to purchase existing premises. Conversion of premises had accounted for 27 loans totalling £111,050, and 26 loans totalling £107,550 had been made for repayment of loans raised from other sources for the purchase of premises, etc.

Twelve loans had been made for the repayment of bridging loans for purchasing premises and/or making conversions amounting to £67,200, and 21 loans totalling £47,350 had been made to enable general practitioners to purchase a share in practice premises.

Branch and Division Meetings to be Held

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

ARMAGH AND WEST DOWN DIVISION.—At Ardmore Hotel, Newry, Thursday, 23 November, 8.30 for 9 p.m., dinner dance. Guests are invited.●

AYRSHIRE DIVISION.—At Ballochmyle Hospital, Cairne, Sunday, 26 November, 7.30 p.m., B.M.A. lecture by Dr. J. J. R. Duthie: "Rheumatoid Arthritis."

BLACKBURN DIVISION.—At De Tabley Hotel, Ribchester, Thursday, 23 November, 8.30 p.m., annual dinner dance.●

CARDIFF DIVISION.—At Park Hotel, Thursday, 23 November, 7.30 for 8 p.m., autumn supper meeting. Mr. Gwynfor Evans, M.P.: "This Wales."●

CLEVELAND AND MIDDLESBROUGH DIVISION.—At Corporation Hotel, Middlesbrough, Thursday, 23 November, 8.30 p.m., B.M.A. lecture by Dr. I. G. W. Pickering: "Crime and the Treatment of the Offender."

COVENTRY DIVISION.—At Lecture Theatre, Walsgrave Maternity Hospital, Tuesday, 21 November, 8.15 p.m., discussion: "A Reappraisal of Pelvic Examination." Speakers: Mr. J. L. Marcus, Mr. M. E. E. White.

DORSET DIVISION.—At Postgraduate Medical Centre, Dorset County Hospital, Dorchester, Wednesday, 22 November, 8.30 p.m., Dr. P. Robinson: "Recent Trends in Neurology."

DUDLEY DIVISION.—At Nurses' Lecture Room, Guest Hospital, Friday, 24 November, 8.30 p.m., annual general meeting.

EAST HERTS DIVISION.—At Herts and Essex General Hospital, Bishops Cleeve, Tuesday, 21 November, 8.15 p.m., clinical meeting.

EAST KENT DIVISION.—At "Chez Laurie," Thanet Way, Herne Bay, Thursday, 23 November, 7.30 for 8 p.m., annual medico-legal dinner. Speaker, Dr. J. D. K. Burton.●

EAST SUFFOLK DIVISION.—At Ipswich Postgraduate Medical Centre, Wednesday, 22 November, 8.15 p.m., Dr. O. Morton: "Recent Advances in Oral Contraception."

EXETER DIVISION.—At Library, Royal Devon and Exeter Hospital, Thursday, 23 November, 8.30 p.m., meeting and election of representatives to Annual Representative Meeting, followed by Dr. John Lloyd: "Why I Came Back."

GLASGOW DIVISION.—At Maurice Bloch Lecture Theatre, Royal College of Physicians and Surgeons of Glasgow, Monday, 20 November, 8.30 p.m., Mr. A. Gibson (Director of the Scottish Opera and Conductor of the Scottish National Orchestra): "Music in Scotland." (One guest not member.)

HUDDERSFIELD DIVISION.—At George Hotel, Friday, 24 November, 8 for 8.30 p.m., annual dinner and dance.

LEEDS DIVISION.—At Guildford Hotel, Wednesday, 22 November, 8.45 p.m., meeting and discussion: "Drugs and Young People." Speakers, the Bishop of Pontefract, the Rt. Rev. E. Treacy, Dr. W. A. Weston. (Preceded by dinner, 7.45 p.m.) Ladies are invited.●

LEWISHAM DIVISION.—At Mermaid Theatre Restaurant, Thursday, 23 November, 7 p.m., dinner-theatre party, "Climb the Greased Pole."●

MAIDSTONE DIVISION.—At Preston Hall Hospital, British Legion Village, Friday, 24 November, 8 p.m., wine and cheese party, one-hour film show, followed by annual general meeting.

MANCHESTER DIVISION.—At Boyd House, Tuesday, 21 November, 8.30 p.m., Mr. F. G. Wood: "Alcoholics Anonymous." Guests are invited.

MIDLAND BRANCH.—At Postgraduate Centre, Selly Oak Hospital, Thursday, 23 November, 8.15 p.m., Clinicopathological Section meeting.

NORTH BEDFORDSHIRE DIVISION.—At Medical Institute, Bedford General Hospital, South Wing, Thursday, 23 November, 8.30 p.m., special general meeting to elect representative to Annual Representative Meeting.

NORTH DEVON DIVISION.—Friday, 24 November, clinical evening.

NORTH MIDDLESEX DIVISION.—At Outpatients' Department, North Middlesex Hospital, Tuesday, 21 November, 2 p.m., clinical meeting.

PLYMOUTH DIVISION.—At North Friary House, Greenbank, Thursday, 23 November, 8.30 p.m., jointly with Pharmaceutical Society, Professor F. E. Camps: "Poisoning, Accident, Suicide, or Murder?" (Preceded by dinner at Duke of Cornwall Hotel, 7 for 7.15 p.m.)●

RENFREWSHIRE DIVISION.—At Lecture Hall, Administrative Block, Bridge of Weir Hospital, Sunday, 26 November, 3.30 p.m., annual general meeting.

ST. MARYLEBONE DIVISION.—At Royal Society of Medicine, Tuesday, 21 November, 7 p.m., meeting: "Medical Aspects of Adult and Teenage Crime." Speakers will include Dr. W. Lindesay Neustatter, Judge G. Rogers, Mr. A. McLean. Guests are invited.

SCARBOROUGH DIVISION.—At Board Room, Scarborough General Hospital, Thursday, 23 November, 8.30 p.m., B.M.A. lecture by Mr. W. Mills: "Modern Methods of Contraception."

SOMERSET DIVISION.—At County Hotel, Taunton, Thursday, 23 November, 7.30 for 8 p.m., annual dinner and dance. Guests are invited.●

SOUTHAMPTON DIVISION.—At Hampshire Suite, Skyway Hotel, Friday, 24 November, 7.30 for 8 p.m., annual ball.●

SOUTH-WEST WALES DIVISION.—At Hotel Mariners, Haverfordwest, Saturday, 25 November, 7 for 7.30 p.m., dinner meeting; 8.30 p.m. (approx.), Professor H. Scarborough: "Management of Chronic Renal Failure."●

SUNDERLAND DIVISION.—At Medical Society Lecture Room, Sunderland General Hospital, Thursday, 23 November, 3 p.m., annual address by Professor S. Shuster, followed by annual dinner at Seaburn Hotel, 7.30 for 8 p.m.

SWINDON DIVISION.—At Princess Margaret Hospital, Friday, 24 November, 8 for 8.30 p.m., annual dinner dance.●

TYNESIDE DIVISION.—At Grand Hotel, Tynemouth, Thursday, 23 November, 8.30 p.m., B.M.A. lecture by Dr. Alan L. Bass: "Sponging Around the World."

WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION.—At gymnasium of Pontefract General Infirmary, Wednesday, 22 November, 8 p.m., clinical meeting.

WINCHESTER DIVISION.—At Board Room, Royal Hampshire County Hospital, Winchester, Saturday, 18 November, 7 p.m., annual general meeting, followed by reception at Postgraduate Medical Centre.

WEST SUFFOLK DIVISION.—At Drummond Hall, West Suffolk General Hospital, Bury St. Edmunds, Tuesday, 21 November, 8.30 p.m., B.M.A. lecture by Dr. J. D. J. Havard (Under-Secretary, B.M.A.): "Recent Legislation Affecting the Medical Profession."

EAST ANGLIAN REGIONAL CONSULTANTS AND SPECIALISTS COMMITTEE.—At Bell Hotel, Thetford, Monday, 20 November, 8.30 p.m., meeting.

Ophthalmic Group Committee

At a meeting of the Ophthalmic Group Committee held on 3 November, Mr. A. G. CROSS was re-elected chairman and Dr. D. STENHOUSE STEWART deputy chairman.

Central Professional List

The CHAIRMAN reported on a meeting between representatives of the General Medical Services Committee and representatives of the Ophthalmic Group Committee, the Ophthalmic Qualifications Committee, and the Faculty of Ophthalmologists on 13 October to discuss criteria for admission to the central professional list of ophthalmic medical practitioners.

The Chairman said that he had reminded the representatives of the G.M.S. Committee that the fundamental requirements for acceptance of any doctor on the central professional list were that he should have the Diploma of Ophthalmology and two years' full-time (or its equivalent of six sessions a week) experience in ophthalmology. The G.M.S. Committee had asked for some modification in these requirements.

The Group Committee agreed that the Diploma of Ophthalmology and two years' experience should remain the criteria for admission to the central professional list.

The next matter to be discussed by the joint meeting, said the CHAIRMAN, had been the constitution of the Ophthalmic Qualifications Committee. The G.M.S. Committee's representatives had thought that a period of membership of the committee of six years was too long, and they wanted a shorter period—say three years. They had welcomed the suggested addition to the Ophthalmic Qualifications Committee of a general practitioner whose name was on the central professional list, but had thought there might be difficulty in finding a nominee. They had also asked for provision for the appointment of a deputy.

Mr. N. CRIDLAND referred to the period of service on the Ophthalmic Qualifications Committee, and said that in his view it did not matter much whether election to the committee was for six or three years. Appointment for six years was perhaps wiser. It ensured continuity in a committee which had a difficult task to perform and much of whose work depended on its own precedents.

Mr. T. KEITH LYLE suggested that if it were common practice for members to be re-elected, which apparently it was, it would be simple to reduce the period. Mr. M. J. GILKES agreed. One of the underlying factors was a feeling that there was a touch of the "old boy network" about it.

The Group Committee agreed that members of the Ophthalmic Qualifications Committee should retire every three years, retiring members being eligible for re-election.

The CHAIRMAN reported that the G.M.S. Committee's representatives had said that it might be difficult to nominate a general practitioner to the Ophthalmic Qualifications Committee whose name was on the central qualifications list and who was also a member of the G.M.S. Committee. Mr. CRIDLAND said that the G.M.S. Committee could co-opt such a member. The CHAIRMAN thought that if a doctor was a member of the Ophthalmic Qualifications Committee he ought also to be on the central professional list. The G.M.S. Committee had also asked that there should be a

deputy for the general-practitioner member, the Chairman said, and there seemed to be no objection to that provided the deputy's name was also on the central professional list.

Mr. GILKES proposed, and the Committee agreed, that the general-practitioner member of the Ophthalmic Qualifications Committee should be on the central professional list and that provision for a deputy would be welcomed, provided the deputy was also on the central list.

Membership of Appeals Committee

The CHAIRMAN said that the G.M.S. Committee's representatives had thought that it was undesirable for a member of the Ophthalmic Qualifications Committee to serve on the appeals committee that considered appeals from doctors who had unsuccessfully applied to the Ophthalmic Qualifications Committee to have their names placed on the central professional list of ophthalmic medical practitioners. An appeals body, they thought, should not include members who had already taken a decision on the case. They had envisaged that a representative of the Ophthalmic Qualifications Committee would present the Committee's case but would not join in the discussion. The G.M.S. Committee's representatives had also hoped that there would be some general-practitioner representation on the appeals committee, and that the possibility of increasing the Ministry of Health's representation might be considered.

Mr. GILKES said that he strongly agreed with the view, expressed by the G.M.S. Committee's representatives, that the appeals committee must not consist of people who made the original judgement. The CHAIRMAN said that the ophthalmic representatives had thought it essential for a member of the Ophthalmic Qualifications Committee to be present at an appeal to put the case. Mr. CRIDLAND said that any appeals committee could either be completely free to make any decision it desired, irrespective of the regulations, or it could feel bound by the regulations even if it chose to interpret them liberally at times. Mr. V. PURVIS agreed that those who judged a case should not also be judges at an appeal.

Mr. P. D. TREVOR-ROPER suggested that any appeals committee should have large representation from the Ophthalmic Qualifications Committee, because the problem was always that of precedent. Mr. GILKES pointed out that it had been made clear that in any independent appeals committee the precedents set would be precedents only for a particular case. Mr. KEITH LYLE said that an appeals committee must be properly constituted, and it would be wrong to have on it members of the Ophthalmic Qualifications Committee with voting powers. It should be completely independent.

Mr. CRIDLAND said that if an appeals committee was to be bound strictly by regulations and was to differ from the Ophthalmic Qualifications Committee only in the way it interpreted the regulations it did not matter what its composition might be.

The Group Committee agreed that the membership of an appeals committee should consist of a member of the Group Committee, a member of the Faculty of Ophthalmologists, a member of the National Ophthalmic Treatment Board Association, a general practitioner on the central professional list, a representative from

the Ministry of Health, and a member of the Ophthalmic Qualifications Committee in attendance but not voting.

The Group Committee also agreed that exceptional cases which were clearly outside the regulations would be referred to the Group Committee by the Ophthalmic Qualifications Committee.

Residential Appointment Necessary

The CHAIRMAN said that another point discussed with the G.M.S. Committee's representatives had been the requirement of a general practitioner applying to go on the central professional list that he should have had at least six months in a resident hospital appointment in ophthalmology. Only if the practitioner had been qualified for over seven years would the Ophthalmic Qualifications Committee waive this requirement. The G.M.S. Committee's representatives had thought that that period should be reduced to five years. They accepted the need for adequate ophthalmic experience, but wished a general practitioner to be able to obtain that in the shortest possible time. It was suggested that there might be a scheme for trainee ophthalmic medical practitioners and that their experience could count towards approval for the central professional list.

The Group Committee decided that the period of experience should not be reduced any further. The Group Committee also thought that there was no substance in the suggested scheme for trainee ophthalmic medical practitioners.

Solar Retinopathy

Mr. GILKES drew the attention of the Group Committee to a paper by Dr. A. E. A. Ridgway on solar retinopathy (*B.M.J.*, 22 July, p. 212). The author had advocated more effective methods of prevention, and had urged that the public should be warned of the dangers. Mr. Gilkes recalled that it was a point he and his colleagues had made when they took the matter up before a major eclipse in 1961. He said that representations should be made to the Ministry suggesting that it should issue a national warning before every solar eclipse about the dangers of looking directly at the sun and of using inadequate filters. The Ministry should be told that representatives of the Group Committee would be prepared to discuss the matter with the Ministry.

The Committee agreed to Mr. Gilkes's suggestion.

Mr. PURVIS emphasized that polaroid sunglasses offered no protection against the sun's rays, and the importance of making that known to the public.

Hospital Medical Staff's Negotiators

The Joint Consultants Committee (J.C.C.) has appointed the following as its representatives on the Negotiating Subcommittee of the Central Committee for Hospital Medical Services (C.C.H.M.S.): Sir John Richardson, Bt. (chairman of the J.C.C.); Mr. T. L. T. Lewis (in place of the vice-chairman of the J.C.C., Mr. Walpole S. Lewin, who is one of the C.C.H.M.S. representatives on the Subcommittee); Dr. C. W. Clayson, P.R.C.P.Ed. (representing Scotland); and Dr. K. Robson and Dr. D. P. Stevenson (Joint Secretaries of the J.C.C.).

The Central Committee for Hospital Medical Services at its meeting on 20 October (*Supplement*, 4 November, p. 36) deferred until its meeting on 14 December the appointment of the Negotiating Subcommittee for 1967-8, and it reappointed the existing Interim Negotiating Subcommittee to complete the preparation of evidence for the Review Body.

Public Health Medical Officers' Salary Claim

At a meeting on 16 November the B.M.A.'s Public Health Committee considered an amendment to the offer of the Management Side of Whitley Committee C in response to the public health medical officers' salary claim (*Supplement*, 28 October, p. 27). After some debate the Committee resolved:

"That the Council be informed that a firm offer has now been received from the Management Side of Committee C to the claim on behalf of public health medical officers. This offer, though not entirely satisfactory, does in the opinion of the Committee represent an acceptable basis for the conclusion of negotiations, and the Staff Side has been asked to negotiate a number of drafting amendments to the offer. The Committee therefore recommends that the

ban on advertisements for local authority medical appointments in the *B.M.J.* be removed."

Dr. C. METCALFE BROWN was in the chair. The Committee's recommendation will be before the Council at its meeting on 29 November.

Travelling Expenses

Dr. David Owen, of Fishguard, failed to persuade the Court of Appeal that travelling expenses from his home to hospital for emergency cases ought to be deductible for income tax purposes under Schedule E (*The Times*, 6 November).

Dr. Owen carried on general practice in Fishguard and held part-time appointments as obstetrician and anaesthetist at the Pembroke County War Memorial Hospital in Haverfordwest, 15 miles from Fishguard. He had to do stand-by duty and "flying squad" duty. All his work at the hospital was to do with emergency cases.

The Court of Appeal found by a majority (Lord Denning dissenting) that Dr. Owen was not performing the duties of his office while travelling. It was not a necessary part of his duties that he should live 15 miles from his place of work, and the expenses were not "wholly exclusively and necessarily" incurred in the performance of the duties of his office. Accordingly the appeal was dismissed. Leave was granted to appeal to the House of Lords.

Memorial to Dr. Kate Harrower

On 7 November the General Medical Services Committee (Scotland) remembered one of its most distinguished former members, the late Dr. Kate Harrower. During a short ceremony the chairman, Dr. A. A. CLARK, recalled Dr. Harrower's outstanding contribution to general practice in Scotland (see *B.M.J.*, 10 December 1966, p. 1459). As a memorial to her a watercolour, "A West Coast Bay," has been hung on a wall of the committee room in the B.M.A.'s Glasgow Regional Office, with which Dr. Harrower had close associations. It was presented by past and present members of the G.M.S. Committee (Scotland), together with members of the Scottish Council of the British Medical Association.

Association Notices

Fellowship and Awards for Medical Research

The Council of the British Medical Association invites applications for the following fellowship and research awards.

Fellowship

A new whole-time research fellowship to the value of £1,500 is offered to assist research into any subject relating to the causation, prevention, or treatment of disease. It will be tenable for one year, and normally renewable for a second year subject to a satisfactory progress report.

Research Awards

The Council will also consider applications for the Ernest Hart and Walter Dixon Research Awards, each up to the value of £300, and other research awards. The awards are granted to assist

specific research work in any subject relating to the causation, prevention, or treatment of disease.

Applications for the fellowship or research awards should be submitted not later than 27 January 1968. The appropriate form and information on the conditions of the awards are obtainable from the Secretary, British Medical Association, Tavistock Square, London W.C.1.

DEREK STEVENSON, Secretary.

General Medical Services Committee

The G.M.S. Committee was reluctant to agree that the B.M.A.'s independent Planning Unit should examine the provision of primary medical care in Britain to see what modifications were needed in the light of changes in medicine. Many speakers feared that the Planning Unit's opinions would be taken to be those of the B.M.A., and some thought that some publicly stated views of the Unit's director, Professor Henry Miller, might seem to have prejudged the issues. One member thought it was the Committee which was doing the prejudging. Other speakers were insistent that the G.M.S. Committee should get a preview of the Unit's report in order to comment on it early. Mrs. M. Jefferys, the lay chairman of the Planning Unit's working party on primary medical care, and Dr. D. H. Irvine, one of its members, are to be asked to meet the G.M.S. Committee's Planning Subcommittee, and later Professor Miller is to be asked to meet the G.M.S. Committee itself. General practitioners are to be encouraged to upgrade the ancillary staff they employ, so that general practice should compete more equally with hospitals as employers of medical secretaries. There were many criticisms of the Government's proposed legislation on drugs and medicines, and it was decided to recommend that a B.M.A. deputation should put the points raised to the Minister of Health.

A meeting of the General Medical Services Committee of the B.M.A. was held on 16 November. Dr. J. C. CAMERON was in the chair.

Recruitment to General Practice

The Committee discussed the latest figures on recruitment to general practice, which had been provided by the Medical Practices Committee.

Dr. A. ELLIOTT said he thought that the Committee should express its apprehension. Though the Ministry had said that the number of doctors was increasing, more were needed to keep pace with the increase in population.

Dr. T. J. CARTER wanted to know what offers the Ministry had made to British doctors in Canada and the United States to coax them back. Had any promises been made to them, and were their return travelling expenses paid?

The Committee agreed to record its continuing anxiety about the number of general practitioners.

Ancillary Staff

Dr. A. A. CLARK, Chairman of the G.M.S. Committee (Scotland), commented on a letter from the Scottish Home and Health Department on the subject of direct payments to general practitioners for the cost of ancillary help. The letter stated that every second Scottish practice (which meant much more than every second doctor) employed ancillary staff, with on average two ancillaries working hours equivalent to about 1.2 full-time workers. In Scotland a full-time ancillary (commonly described as a secretary/receptionist or simply as a receptionist) could expect to be paid rather less than £100 a quarter or £400 a year. That, the letter continued, was of "particular interest in view of the suggestions that have been made from time to time that there should be 70% reimbursement of salaries up to a higher level than the existing £500 per annum."

Dr. Clark said that unfortunately the majority of receptionists trained at a college in Glasgow obtained work in hospitals at the end of their 12 months' training, because they were paid better in hospitals than in general practice.

Dr. W. W. FULTON said that the better girls from the college who went into hospitals were successful in being graded as personal secretaries at £668 a year, and if they had higher typing or shorthand speeds they could earn up to £776 a year at the age of 18. General practitioners could not pay that. Dr. B. ALEXANDER said that in many parts of England ancillary staff could not be obtained at £400 a year. Dr. D. R. COOK also agreed that that salary did not apply

in England. Girls who had the Diploma for Medical Secretaries were recommended by the college that trained them for salaries of between £800 and £1,000 a year. That indicated the kind of salary doctors in the London area had to pay for a reasonably trained ancillary worker.

Dr. A. ELLIOTT pointed out that the girls who took the training course for general-practice receptionists were usually young, and there was a good case for encouraging more mature students to take the course. If doctors would pay a more realistic figure they could expect a more realistic reimbursement from the Ministry. Mature students were not interested only in the financial side if the work was interesting.

The Committee decided that doctors should be encouraged to upgrade the ancillary staff they employed.

Expenditure on N.H.S.

The Committee considered a reference from the Council of the following resolution of the Annual Representative Meeting 1967: "That this meeting has grave doubts whether the wishes of the public are being carried out in regard to the proportion of the national income spent on the N.H.S. That it be a recommendation to the Council of the Association to consider employing the modern techniques of sampling public opinion to obtain evidence of this question."

Dr. I. M. JONES said that few people had any accurate knowledge of how the N.H.S. was paid for or how the social services in general were financed. The B.M.A.'s planning unit was to conduct a survey which could provide some information on the matter in question.

Dr. R. B. L. RIDGE said that a survey of the type suggested in the A.R.M. resolution would be a fairly expensive undertaking. Even if an expression of public opinion was obtained of what use would it be? The strength of the Association lay in its knowledge of professional matters, not in making a case on behalf of the public. He hoped that the Committee would advise the Council that it could see no useful purpose being served by the B.M.A. undertaking an inquiry of this nature.

Dr. B. D. MORGAN WILLIAMS disagreed with Dr. Ridge. Once upon a time the B.M.A. had been one of the strongest pressure groups in the country. If it did a survey and the results were published people would take notice of it. Dr. R. A. KEABLE-ELLIOTT said that he thought the wishes of the public were not being carried out, but he could conceive of no greater waste of money than to carry out a survey of public opinion. It was nonsense to think that the Government would "rush off and spend more money on the N.H.S."

Part of a Whole

Dr. H. N. ROSE pointed out that the whole of the country's budget would have to be considered—how much was spent on defence, how much on education, how much on welfare, and so on. The doctors thought that not enough money was spent on health, but it was not for them to say where the money should come from. It was Parliament's job to determine what proportion of the national income was going to be spent on the Health Service.

Dr. G. CORMACK said that implicit in the motion was a belief that the amount of money spent on the N.H.S. could be increased. The amount of money expended on any particular activity could be only a percentage of the total national expenditure, and in the last resort only the Government could decide how much was spent on each activity. All doctors could do was to compare what was spent on health in this country with what was spent in other countries with a comparable standard of living. A comparison could be made with the United States, where people could spend their money largely as they wished, and they chose to spend a greater proportion on health—about 2% more.

Dr. J. E. MILLER said that if such an expensive undertaking (the Committee was advised that a worth-while survey would cost £50,000) was to be paid for by, among others, the general practitioners' defence trusts the

Committee would have to be sure that it was going to yield some benefit not only to the profession and to the N.H.S. but also to doctors in the other branches of the Service.

Dr. I. M. JONES said that it had been shown that the health of a nation could be related to the proportion of its income that it spent on health services. In the world league table Britain came no higher than eighth. Where the money came from was another issue, and it was an issue on which the attitude of the British public was not known. The extra money needed to bring the standard of the British health services up to the best in Europe was about £500m. to £600m. a year. To get that out of taxation would mean the equivalent of 2s. more on the standard rate of income tax. The money would have to come either from indirect taxation or from what people spent themselves on consumer goods and services. Such surveys as had been carried out indicated that many people would be willing voluntarily to spend their money on their health. In the last resort money spent on the community came from the community. The debate was whether it should come almost exclusively from taxation or whether usefully and with advantage to the whole community it could come from other sources.

The Committee decided to defer further consideration of the matter until a future meeting.

Association's Planning Unit

The CHAIRMAN outlined to the Committee the steps that had been taken to set up the B.M.A.'s Planning Unit under the direction of Professor Henry Miller, of Newcastle upon Tyne. It had set up various groups to study particular subjects in detail—one on intensive medical care, another on aids to the disabled, another on the use of computers in medicine, and so on (*Supplement*, 14 October, p. 14).

One of the subjects which the Planning Unit was going to study was the provision of primary medical care. A working party had been appointed with Mrs. Margot Jefferys, director of the social research unit, of the department of sociology, Bedford College, London, as its chairman. The CHAIRMAN (Dr. CAMERON) said that he had met Professor Miller and had proposed, bearing in mind the interest and responsibility which the G.M.S. Committee had in the matter of primary medical care, that there should be a joint working party of the G.M.S. Committee and the Planning Unit. Professor Miller had thought that the G.M.S. Committee's activities were more in the medico-political field. He did not think that a joint working party was a good idea, because it was essential that the Planning Unit should maintain its independence. Any report it produced should not be influenced by any other body.

The Chairman said that he had then suggested to Professor Miller that two or three members of the G.M.S. Committee might join the Planning Unit's primary medical care working party, because the Committee was anxious that no publication should throw any doubt on to the future of general practice. He had then invited Professor Miller at some date to meet the G.M.S. Committee to discuss the matter.

Letter from Professor Miller

The Committee had before it a letter to Dr. Cameron from Professor Miller, which, after referring to their discussion, continued as follows:

"The Planning Unit recognizes that, however it is furnished, the provision of primary medical care is the bedrock of the Health Service. It also appreciates that if this provision is to keep pace with the rapid changes that are occurring throughout medicine it is bound to need progressive modification. As you know, there are many views on how new needs can best be met, ranging from the provision of specialist polyclinics on the Central European pattern to a thorough upgrading of general practice as a career in the matter of more extended postgraduate training, improved physical facilities, grouping of practitioners, possibly some degree of specialization within group practice, and the possibility of frequent hospital attachment. My personal guess would be that the second alternative is the more likely ultimately to prevail under British conditions, and indeed it seems that the Ministry is steadily moving in this direction. At any rate the advantages and disadvantages of these two approaches and of many immediate possibilities will be examined carefully and objectively, and as far as possible an attempt will be made to cost the various possible arrangements. . . .

"The nucleus of the Working Party has been carefully selected to try to achieve a combination of intimate personal experience with present general practice with the freshness of approach that can be brought to it by expert opinion from outside the profession. It must be emphasized, however, that it is a collection of individuals and in no sense whatever of representatives of any special interests. . . . I am certain that if its report is to be useful it will take a considerable time to prepare. We don't wish to produce merely another discussion of generalizations.

"There is, I am sure, no need for me to point

out that the purpose of the Planning Unit and its working parties is to take a fresh look at a series of problems of contemporary medicine and in no sense to formulate policy. We aim to discuss alternative solutions and to try to weigh their respective advantages and disadvantages. No source of relevant evidence or opinion will be overlooked.

"At some stage I would be pleased to talk to the G.M.S. Committee either about the work of the Planning Unit in general, or, if this were considered too diffuse, about the particular approach of the Working Party on Primary Medical Care. However, I really feel there is nothing I can say now in this last connexion that would amount to more than the facile generalizations with which we are all too familiar. When we have got our teeth into the problem I think it would be worth while talking to your committee and to sound its opinion about the various aspects of the problem we are investigating."

Brick by Brick

Dr. RONALD GIBSON, Chairman of Council, pointed out that the Planning Unit was not a committee of the Association. It had been thought that the Association's committees were so overburdened with current work that they might not have the time to look to the future. They had been caught out on this in the past and had been criticized for it. It was hoped that any committee of the Association, or the Council, or the Representative Body would commission the Planning Unit to examine subjects which were of importance or to deal with a section of that subject. The Planning Unit would give the committee its views resulting from its detailed study. In the case of primary medical care the working party and the Planning Unit would go through their project brick by brick and build up the structure of the Health Service. The G.M.S. Committee would be free to comment in any way it wished on the Planning Unit's report when it was published.

When Professor Miller had used the word "independent," he meant that he wished to be independent of any committee of the Association, said Dr. Gibson. If the G.M.S. Committee asked for representation on the Planning Unit then the Central Committee for Hospital Medical Services and the Public Health Committee would want representatives, and the unit would become another B.M.A. committee. If the Association was not seen to be doing this kind of future planning the Ministry or another association or college outside the B.M.A.'s control would do it.

Dr. CORMACK said that the Planning Unit, with Professor Miller as its director, had been appointed and the B.M.A. had to accept the consequences. One consequence was that it had "a tiger by the tail," with all the difficulties which ensued when it might want to let go. Professor Miller was a radical thinker. For him to direct a planning operation for what was perhaps a rather conservatively minded profession was bound to cause misgivings to some people. Dr. Cormack said there was a good case for setting up a planning unit—the old Amending Acts Committee had been a good example of how ineffective a committee of the Association could be in planning work. He thought it would be a mistake for the G.M.S. Committee to appoint anyone to the working party. It was better that the Committee's point of view should be heard, and then they should leave it to the working party to get on with their

planning. He was sure that Professor Miller would give good reasons for any recommendations he made. Though the Planning Unit's report should be published, the B.M.A. committees concerned should be allowed to publish their own commentary at the same time.

Prejudging Issues

Dr. J. E. MILLER said he did not cavil at the appointment of a radical thinker as director of the Planning Unit. However, it should not be forgotten that the unit had been established by the British Medical Association and its activities would be seen as representing the views of the B.M.A. Some of Professor Miller's pronouncements, particularly about general practice, had already been taken to represent the views of the Association. Dr. Miller said that he knew the Planning Unit had been set up as an independent body, and as such ought to be allowed to do its work and to publish its results, but when pronouncements made by its chairman seemed to prejudice issues before the unit had done its work and seemed to represent a contrary view from that held by the vast majority of members of the B.M.A. "we should reconsider our position." He thought it was "highly improper" that at such an early stage in the activities of the Planning Unit statements should appear which in effect were an attack on general practice as it was today and the possibility of general practice in the future. "We must call a halt, because the periphery will ask 'Is this the view of the Association?' . . . Professor Miller and the members of his unit should hold their tongue on the views which they hold until such time as they have analysed the situation and provided a report which can be balanced by the views of the various committees which they are asking for information from."

Spawn a Monster

Dr. H. S. HOWIE WOOD said that the Chairman of Council had told the Committee about bricks being used to build up a new structure. He (Dr. Howie Wood) would like an assurance that that would not be brought about by pulling down the brickwork of "our old established structures. One can be destructive or constructive. I am sure that the Chairman of Council knows his man, but it is possible to spawn monsters. There is just the possibility that the B.M.A. will get more than it bargained for if we do not have an assurance that any report will come to us before it ever reaches the outside world."

Dr. ALEXANDER said he was "disappointed and disheartened." This was a Planning Unit of the B.M.A. and was financed by it. It would have the imprint of the Association, and such reports as were printed would be quoted as Association policy. "We are the primary physicians; we are the people responsible for and entrusted with primary medical care in this country; we are the people who should be represented on this working party. I do not think we should have anything to do with the Planning Unit until we are represented on the working party. We have been speaking in metaphors—it is possible to put tigers in cages."

Dr. COOK said that he was unhappy about the working party. The chairman was a woman of experience. The doctors on it were

in the early years of their professional life. There ought to be a general practitioner on the working party who had spent many years in general practice. It was not entirely correct to say that if the G.M.S. Committee was represented other committees should also be represented, because primary medical care specifically concerned general practitioners.

Dr. RIDGE said that to make projections based on ascertained facts and to devise a plan to deal with an expected situation was a scientific process, and it was proper to employ a scientific method of planning. In that context a planning unit of the type set up was appropriate to the British Medical Association. However, primary medical care was not a subject which was wholly scientific. There was still a not inconsiderable element in it which was art, and the development of an art could not be planned. The Fraser Working Party had come to the conclusion that the doctor-patient relationship could not be evaluated. It was a question of art and not of science. General practice developed in response to the demands of its clients.

Preconceived Views

Dr. SPEAKMAN was confident about the future for general practice, but he was afraid that any preconceived views of the director of the Planning Unit, of whatever good intent, would filter through as the views of the B.M.A. Public opinion was formulated in a subconscious way. Something said often enough began to be believed. Professor Miller should not make any public statements before the official report of the Planning Unit had been published.

Dr. A. ELLIOTT said that primary medical care was exercising the minds of doctors all over the world. He looked forward to the publications of the Planning Unit, so long as the G.M.S. Committee was not committed to the unit's views. The Committee must reserve the right to examine any of the unit's reports.

Dr. E. TOWNSEND said: "I have listened to the debate with some dismay. We have in our wisdom in the Association decided to have a planning unit. We have appointed a very well-known, perhaps controversial, figure, and given him a job . . . let him get on with it and let him see what he can do. We have been accusing him of prejudging the situation, yet we have proceeded to prejudice him here. If you read his letter carefully he says that he is already persuaded that there is a future for general practice and that he thinks that general practice is going to alter along the lines that it is beginning to alter now. . . . Surely none of us thinks that general practice is going to go on in its present form. Our younger colleagues do not think so, and many of our older ones don't. They find it an unattractive branch of the profession. . . . General practice has not caught up with the other services. Here is a man with new ideas, a man with great intelligence, perhaps with advanced views which may not meet with our approval. We should give him our blessing. Let us hear what he has to say and then criticize."

Dr. GIBSON, replying to the debate, said it was unfair to say that Professor Miller was against general practice. He had mentioned polyclinics, and it had been suggested that that was prejudging the issue, but it would be foolish to discuss the future of general practice without discussing the possibility of polyclinics—if only to get rid of them. He agreed that the G.M.S. Committee must not be asked to commit itself to the views of the working party. The Planning Unit was not a policy-making body: it investigated, and it produced its views.

The Committee agreed that Mrs. Jefferys and Dr. D. H. Irvine, a member of the working party, should be asked to meet the G.M.S. Committee's Planning Subcommittee in the first instance, and that later Professor Miller should be invited to meet the G.M.S. Committee.

Drugs Legislation

The Committee considered the Government's White Paper on the forthcoming legislation on the safety, quality, and description of drugs and medicines (*B.M.J.*, 16 September, p. 734).

Dr. RIDGE explained that the two particular issues which concerned the Committee were the procedure to be adopted before a drug was licensed for sale or supply and the procedure for issuing licences. The Sainsbury Committee had recommended the setting up of a medicines commission, and this was in line with the B.M.A.'s evidence. The Sainsbury Committee recommended that the examination of a preparation for efficacy, toxicity, and safety should be the function of the medicines commission, with advice from expert bodies. The White Paper reserved to the Ministers both the power for making regulations relating to the preliminary stages and the power to issue, withhold, or withdraw licences for preparations to be sold or supplied.

Dr. Ridge said that this raised the question of interference with the freedom of general practitioners to prescribe any preparation which they thought necessary for the treatment of a patient, because the Ministers

would have powers which could conceivably prevent the introduction of a new preparation, prevent its availability for supply, and, even more seriously, they could do a retrospective examination at a later date of any preparations currently in use.

Much would depend, said Dr. Ridge, on the membership of the medicines commission and the expert committees. It was suggested that some 20 organizations should be consulted about the membership of the medicines commission. The B.M.A. would be lucky if it got two members and might get only one, who might or might not be a general practitioner. He would have to battle against some high-powered members in the pharmaceutical field on whether a drug should be available for use by general practitioners.

The most important aspect was who had the statutory power. The Minister of Health was a principal consumer of the drug industry's products. On many occasions in the past Ministers had wanted to exercise control over prescribing. The Minister could, under new legislation, use his powers under licensing or in the preliminary stage, to influence the drug bill in the National Health Service. It might be proper for him to do

this provided his actions were dictated solely by scientific evidence.

Dr. Ridge hoped the Committee would express to the Council its disquiet that the Minister of Health should be the Minister responsible for licensing in relation to new preparations, and at a later date for licensing in relation to all preparations currently in use.

Bureaucratic Machine

Dr. S. WAND said that the White Paper envisaged an enormous bureaucratic machine. Paragraph 16 of it stated: "If the Commission wished, as it well might, to recommend the appointment of separate expert committees for human drugs, for veterinary aspects, and for devices it would be able to do so. It would be open to it to recommend to Ministers the names of persons knowledgeable in the relevant field, whether members of the Commission itself or not, who would in the opinion of the Commission be suitable for appointment to particular expert committees. After considering the Commission's advice and consulting appropriate organizations the Ministers will set up expert committees undertaking function or groups of functions." It was the work of those committees that might affect general practitioners, and it was there that they should have adequate representation. The Commission was likely to accept the advice of its committees.

Dr. MORGAN WILLIAMS said that the Sainsbury Committee had recommended that the medicines commission should be independent. He did not see how a body appointed by the Minister could be considered to be independent. The National Formulary Committee was independent, and he hoped the G.M.S. Committee would suggest that the National Formulary Committee should remain. Dr. Morgan Williams also deplored the haste with which legislation was being rushed.

Adamant Against Advice

Dr. ROSE said it had been urged upon the Minister that he should not be the licensing authority, but he had been absolutely adamant and would not accept that the medicines commission should do the licensing. There were safeguards in regard to licensing. The Minister would not refuse a licence unless he had referred it to the expert committee for its guidance, but it was possible that in an emergency he might be able to refuse to grant a licence.

Paragraph 53 of the White Paper stated that the Minister of Health would have statutory power to prohibit the sale or supply of a drug. That could apply to a drug like heroin. The profession ought to oppose this; reference should be made to the Royal College of Physicians and the B.M.A. when any prohibition of any drug was suggested. Paragraph 72 stated that enforcement in relation to hospitals and similar institutions and in relation to general practitioners would not be delegated. Did that mean that inspection would be done by doctors from the Ministry? Paragraph 74 stated: "Provisions requisite for the purposes of enforcing the legislation will be included—for instance, right of entry and inspection, the procuring, by purchase or on reasonable payment, of samples, the production of appropriate books and documents, the seizure and holding of articles liable to forfeit under the Bill and documents relating to them which may be required in proceedings." The G.M.S. Committee should see to it that the general practitioner's interests were safeguarded.

Authorization

Dr. D. L. WILLIAMS said that the proposals were authoritarian in the extreme. It was said that there would need to be a large increase in Civil Service staff. The proposals gave the impression that the Minister would be able to determine the rate of growth of the

pharmaceutical industry. That was alarming, because the progress of medicine in this country had been restricted by lack of money, yet now the Ministry was being given the responsibility for the growth of the pharmaceutical industry.

Dr. WILLIAMS said his second worry was that the medicines commission would be the principal source of information about drugs. That was control of scientific information, and it was a terrible thing. If its pronouncements were cautious they were valueless: if they were controversial they would give to the opinions of the commission the appearance of being "instant truth."

Dr. FULTON quoted from a letter from the Ministry of Health of 20 October: "The White Paper proposed that the commission should be a professionally independent body exercising mainly advisory functions." That was rather less than the truth. The White Paper actually said that the commission would be appointed by the Ministers after consultation with the appropriate organizations, and later that the Ministers would set up expert committees after considering the commission's advice and consulting appropriate organizations. The bodies were actually being set up by the Ministers. It was important that this statement in the Ministry's letter should be challenged, because it was untrue.

The Committee decided to recommend that the Chairman of Council should be asked to lead a deputation to the Minister without delay to put all the points which had arisen. The Minister should also be asked to restate the assurances which had been given by his predecessors on the general practitioners' freedom to prescribe, subject to the safeguards which had already been agreed.

Remainder of Business

It was decided to postpone considerations of other items on the Committee's agenda until a special meeting on 7 December.

Advanced Specialty Training Courses

A scheme has been agreed by the Ministry of Health and the British Postgraduate Medical Federation to provide selected courses of advanced specialty training for up to 50 hospital doctors at a time. Some of the places will be allocated to doctors from Scotland. The Central Committee on Postgraduate Medical Education (the Aitken Committee) has commended the scheme.

The courses will be at "post-membership or fellowship level," but will not be directed at the fellowship or membership examinations. They will usually last about ten weeks and are intended to assist doctors who have qualified in the United Kingdom and who are undergoing specialist training. The Ministry of Health, in a letter to senior administrative medical officers and secretaries of hospital boards and committees, has stated that attendance at the courses should be regarded as study leave, and hospital boards will be repaid the cost. This will include payment of the trainee's expenses, including the fee for the course, and the cost of a locum tenens when necessary.

Hospital boards will be notified in the autumn of each year of the courses being organized for the year beginning the following April, and they will be expected to tell the appropriate staff.

In making its selection from applicants for the courses the Federation is to give preference to: (1) doctors who have their membership or fellowship; (2) senior registrars approaching consultant posts whose training has omitted important clinical experience or who wish to develop a line of interest; (3) senior registrars in hospitals with restricted range of educational opportunities; (4) consultants who have not had the opportunity for systematic revision of the theoretical basis of their practice, or wish to expand their knowledge in some branch; (5) doctors in understaffed specialties; and (6) doctors returning from overseas or tropical service secondments.

The Ministry hopes that after a time courses may be arranged in centres and institutes other than those comprising the British Postgraduate Medical Federation.

Educating the Public

The Minister of Health is to continue this winter the campaign to educate the public in the use of doctors' services. A Ministry circular states that the Minister "considers it important" that the appeal to the public and the information in the campaign literature should be "pressed home." The continued co-operation of television authorities has been asked for, and leaflets, posters, and stand-up cards for surgeries have been reprinted.

Medical Charities

The Association's Charities Committee is to launch a "medical charities year" as soon as is practicable in aid of the Sir Charles Hastings Fund, the Dain Fund, the Royal Medical Benevolent Fund, and the Royal Medical Foundation of Epsom College. The appeal to begin with will be only to members of the medical profession. An appeals sub-committee will have the help of a paid whole-time organizer in managing the appeal.

It was also decided to rename the Contingency Fund, one of the B.M.A.'s charitable funds, the "Kate Harrower Contingency Fund." Dr. Kate Harrower, who died in 1966, bequeathed £200 to the Charities Trust Fund.

Dr. R. Cove-Smith is the chairman of the Charities Committee.

Medical Assistants

Medical assistants in Northern Ireland have formed a "Northern Ireland Medical Assistants Group," with Dr. Daniel C. S. M. McAlister, Belfast, as its chairman, to consider the problems of the grade which are causing concern, including the term "assistant."

When the grade was first introduced in the United Kingdom many doctors objected to the title "medical assistant," and the Ministry of Health and the Joint Consultants Committee agreed that posts should be advertised as "Assistant in (specialty)." The Central Committee for Hospital Medical Services has since supported a proposal that the new title for the grade should be "Assistant Grade," and that individual doctors should be known as "assistant surgeon," "assistant physician," etc. (*Supplement*, 15 July, p. 67). The C.C.H.M.S. has also set up a working party, with Dr. G. E. Owen Williams as chairman, to consider the particular problems of medical assistants and how they should be represented (*Supplement*, 4 November, p. 30). Mr. J. P. Capel (Bristol) has been appointed to the C.C.H.M.S. to represent medical assistants.

Hospitality

An Italian doctor living in Naples would like his son aged 19 to stay with a British medical family on an exchange basis from 20 December to 15 January 1968. The doctor has seven sons aged from 22 to 6 years.

A French doctor living in Octeville (Manche) would like his 14-year-old daughter to stay with a British medical family living in or near Southampton from 20 December for six weeks as a paying guest. If a paying guest arrangement is unsuitable the doctor will receive in exchange a British girl of similar age during the Easter holidays.

A French doctor living in Brunoy (Seine-et-Oise) would be pleased to receive a British doctor's daughter aged about 14 during the Christmas holidays. In exchange he would like his own daughter aged 14 to stay with the British medical family during the summer holidays.

A French doctor living in Pontivy (Morbihan) would like his 21-year-old daughter to stay *au pair* with a British medical family living in London from January 1968 for 12 months.

Would anyone who is interested please get in touch with Dr. R. A. Pallister, Medical Director, International Medical Advisory Bureau, B.M.A. House, Tavistock Square, London W.C.1.

Was it a Drug?

Regulation 16 of the National Health Service (Service Committees and Tribunal) Regulations, 1956, provides that when a practitioner prescribes under the National Health Service preparations which are not drugs or medicines, and therefore outside the scope of the Act, the executive council may recover their cost from him. If he challenges the council's action the matter may be referred to the local medical committee. Either party or, the Minister can appeal to a referee or referees against the local medical committee's decision.

The referees on each occasion are appointed by the Minister of Health. They must not exceed three in number, and they must not be officers of the Ministry of Health. At least one must be a general medical practitioner. In practice the number of referees appointed has usually been three. The chairman has been a layman with legal training, and his two colleagues have been general practitioners selected from a panel chosen by the General Medical Services Committee of the B.M.A.

The findings* of the referees in some recent appeals under the regulations are reported below. The decisions in these, as in all cases, are related only to the circumstances of the particular cases, and are not binding on referees who may hear other cases.

Chiron Deodorizing Cleanser

The referees considered a case in which Chiron Deodorizing Cleanser had been prescribed for a patient who had had a colectomy for severe ulcerative colitis. On a reference from the executive council the local medical committee had decided that this was a drug which the council was bound to provide.

In their report the referees stated that the cleanser was a cleansing and deodorizing

preparation for use with ileo-colostomy bags. In their opinion it was not a substance which had any pharmacological effect, and they had therefore decided that in this case it was not a drug which the executive council was bound to provide.

ProDermide Solid

The referees also disagreed with the decision of a local medical committee in a case where six tablets of ProDermide Solid had been prescribed for a boy suffering from severe eczema. The executive council had appealed to the local medical committee, which had decided that these tablets were a drug which the council was bound to provide.

The referees were of the opinion that the "soap," while being non-irritating to an eczematous patient, was basically a cleansing agent and had no pharmacological action or effect, and they decided that it was not a drug which the executive council was bound to provide in this case.

Totmosol Soap

The referees considered a case in which six tablets of Totmosol soap had been prescribed for a patient suffering from a chronic skin condition. The local medical committee had decided that this was a drug which the executive council was bound to provide.

In their decision on this case the referees stated that "beyond the fact that the patient suffered from what is described as a chronic skin condition, we have no information as to the nature or degree of the complaint save that it resisted all conventional forms of treatment. In the absence of much fuller information as to the circumstances in which the use of Totmosol soap was prescribed in this case, we are bound to decide that this soap was not a drug which the executive council was bound to provide."

* These findings are normally sent only to the interested parties. They are sent by the Ministry of Health to the B.M.J. with all names deleted.

B.M.A. Nuffield Library

The Library service is available to all members of the Association resident in Great Britain and Northern Ireland (and by special arrangement to members of the Irish Medical Association). A copy of the library rules will be forwarded on application to the Librarian at B.M.A. House.

The following books have been added to the Library:

- Allen, A. C.: *The Skin*, 2nd edition. 1967.
- Ashton, W. L.: *Human Atheroma*. 1967.
- Berrill, N. J.: *Biology in Action*. 1967.
- Bion, W. R.: *Second Thoughts*. 1967.
- Brown, W. M. C.: *Human Population Cytogenetics*. 1967.
- Cartwright, F. F.: *The Development of Modern Surgery*. 1967.
- Chusid, J. G., and McDonald, J. J.: *Correlative Neuroanatomy and Functional Neurology*, 13th edition. 1967.
- Comfort, A.: *The Anxiety Makers*. 1967.
- Cooper, P.: *Ward Procedures and Techniques*. 1967.
- Copel, S. L.: *Psychodiagnostic Study of Children and Adolescents*. 1967.

- Davis, P. E., and Hershelman, N. V.: *Medical Shorthand*. 1967.
- Davison, M. H. A.: *The Evolution of Anaesthesia*. 1965.
- Dawes, E. A.: *Quantitative Problems in Biochemistry*, 4th edition. 1967.
- Drummond-Jackson, S. L. (Editor): *Intravenous Anaesthesia*, 3rd edition. 1967.
- Fiddle, S.: *Portraits from a Shooting Gallery*. 1967.
- Filley, G. F.: *Pulmonary Insufficiency and Respiratory Failure*. 1967.
- Fish, F.: *Clinical Psychopathology*. 1967.
- Fomon, S. J.: *Infant Nutrition*. 1967.
- Ford, E. B.: *Genetic Polymorphism*. 1965.

- Gray's Anatomy, 34th edition. Edited by D. V. Davies. 1967.
- Hartland, J.: *Medical and Dental Hypnosis*. 1966.
- Jeffcoate, T. N. A.: *Principles of Gynaecology*, 3rd edition. 1967.
- Kalmus, H. (Editor): *Regulation and Control in Living Systems*. 1966.

H.M. Forces

A Supplement to the *London Gazette* has announced the following awards:

Territorial Efficiency Decoration.—Lieutenant-Colonel I. W. Pinkerton (now R.A.R.O.), Majors J. L. Butler (now R.A.R.O.), S. M. Frazer, retired, and D. L. Golightly, R.A.M.C.

Surgeon Lieutenant-Commanders J. S. Hales and J. K. Ross, R.N.R., have been awarded the Royal Naval and Royal Marine Forces Reserve Decoration.

Appointments.—Group Captain D. S. Light (radiological duties, Princess Mary's Royal Air Force Hospital, Akortiri); Wing Commander R. C. Robb (to command (with acting rank of Group Captain), R.A.F. Hospital, Changi); Wing Commander J. J. Henry (senior medical officer, Episkopi).

ROYAL NAVY

Surgeon Lieutenant-Commander A. M. MacGillivray has been placed on the Emergency List.

ROYAL NAVAL RESERVE

Surgeon Lieutenant-Commander D. E. R. Richardson has been placed on the Retired List.

The notification concerning Surgeon Lieutenant-Commander R. A. J. Baily, R.D., published in the *London Gazette* dated 4 July 1967, and in the Supplement to the *B.M.J.* dated 5 August, p. 110, has been cancelled.

Surgeon Lieutenant D. M. Jenkins to be Surgeon Lieutenant-Commander.

ARMY

Colonel D. D. Maitland, O.B.E., late R.A.M.C., has retired on retired pay.

ROYAL ARMY MEDICAL CORPS

Majors H. C. Ferguson, W. G. Thomson, R. J. Belas, T.D., and B. P. V. O'Duffy, M.B.E., to be Lieutenant-Colonels.

Major P. A. North has retired, having received a gratuity.

Major J. R. Bannister has resigned his commission.

Short Service Commission.—Captain R. Wilson to be Major.

ROYAL AIR FORCE

Air Commodore A. Muir, C.B., has retired. Squadron Leader J. M. Clifford to be Wing Commander.

Squadron Leaders R. Baird and M. Leahy have been transferred to the Reserve.

Flight Lieutenants I. F. Elliott and N. G. Flanagan to be Squadron Leaders.

Association Notices

Diary of Central Meetings

DECEMBER

- 4 Mon. Scottish Committee for Hospital Medical Services (at 7 Drumsheugh Gardens, Edinburgh), 2.15 p.m.
- 7 Thurs. Junior Members Forum Advisory Committee, 9 a.m.
- 7 Thurs. Organization Committee, 10 a.m.
- 7 Thurs. General Medical Services Committee, 10.30 a.m.
- 7 Thurs. Committee on Therapeutic Abortion, 2 p.m.
- 8 Fri. Planning Unit Committee, 5 p.m.
- 12 Tues. Medical Science Committee, 10.30 a.m.
- 13 Wed. Committee on a Cervical Cytology Service, 2 p.m.
- 13 Wed. Journal Committee, 2 p.m.
- 14 Thurs. General Medical Services Committee (Scotland) (at 7 Drumsheugh Gardens, Edinburgh), 10.30 a.m.
- 28 Thurs. Central Ethical Committee, 10 a.m.
- 28 Thurs. General Purposes Committee, 10.30 a.m.

JANUARY

- 17 Wed. Annual Meetings Committee, 10.30 a.m.
- 26 Fri. Venereologists Group Committee, 2 p.m.

Branch and Division Meetings to be Held

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

BIRKENHEAD AND WIRRAL DIVISION.—At Larch House, Clatterbridge Hospital, Thursday, 7 December, 8 for 8.30 p.m., discussion on "The Effects of Drugs on Driving." Speakers: Professor A. Wilson, Mr. Rex Taylor, Major S. J. Harvey, Dr. F. J. Zacharias.

BOURNEMOUTH DIVISION.—At Postgraduate Medical Centre, Friday, 8 December, 8 p.m., meeting to elect representatives.

BRENT DIVISION.—At Commonwealth Institute of the Royal Postgraduate Medical School, London W.1, Tuesday, 5 December, 8.30 p.m., meeting: "Computers in Medicine."

BRISTOL DIVISION.—At University Senate House, Tyndall Avenue, Friday, 8 December, 8 for 8.30 p.m., banquet and ball.●

CAMDEN AND ST. MARLYBONE DIVISIONS.—At Berners Hotel, Thursday, 7 December, 8 for 8.30 p.m., informal Christmas dinner meeting. Speaker, Mr. Lionel Hale. (Followed by election of Camden representatives to Annual Representative Meeting.) Guests are invited.●

CROYDON DIVISION.—At Selsdon Park Hotel, Thursday, 7 December, annual dinner and dance.●

DARTFORD DIVISION.—At Livingstone Hospital, Thursday, 7 December, 8.15 for 8.30 p.m., meeting to elect representative to Representative Body.

DUNBARTONSHIRE DIVISION.—At Canniesburn Hospital, Thursday, 7 December, annual general meeting.

DURHAM DIVISION.—At Lecture Theatre, Postgraduate Medical Centre, Dryburn Hospital, Monday, 4 December, 8.15 for 8.30 p.m., Dr. Christine Cooper: "Developing Child Health Services in Sierra Leone."

EALING DIVISION.—At Mylett Arms Hotel, Greenford, Thursday, 7 December, 8.30 p.m., annual general meeting. Ladies are invited.

EAST HERTS DIVISION.—At Homestead Court Hotel, Welwyn Garden City, Thursday, 7 December, 9 p.m. (approximately), panel discussion: "Drug Addiction." (Preceded by dinner, 7.30 for 7.45 p.m.) Ladies are invited.●

EAST SUFFOLK DIVISION.—At Ipswich Postgraduate Medical Centre, Friday, 8 December, 8.15 p.m., film meeting: "Chronic Bronchitis"; "The Smallest Enemy."

EAST YORKSHIRE BRANCH.—At Royal Station Hotel, Thursday, 7 December, 8 for 8.30 p.m., annual dinner dance.

ENFIELD AND POTTERS BAR DIVISION.—At Academic Centre, Chase Farm Hospital, Wednesday, 6 December, 8.30 p.m., Brigadier R. V. Phillipson: "Drug Addiction." Medical guests are invited.

FERNANAGH DIVISION.—At Imperial Hotel, Enniskillen, Tuesday, 5 December, 8.30 p.m., meeting, (1) election of representatives to Representative Body; (2) film strip: "The 50,000 Years War."●

FURNESS DIVISION.—At Old England Hotel, Bowness-on-Windermere, Friday, 8 December, 8 for 8.30 p.m., annual dinner dance.●

HARROW AND HILLINGDON DIVISION.—At Whittington Hotel, Cannon Lane, Pinner, Tuesday, 5 December, 8.45 p.m., Lord Moran: "The Life of Sir Winston Churchill."

HAVERING DIVISION.—At Harold Wood Hospital, Sunday, 3 December, 10.30 a.m., annual clinical meeting.

LANCASTER DIVISION.—At Midland Hotel, Morecambe, Friday, 8 December 8 for 8.30 p.m., dinner dance.●

MAIDSTONE DIVISION.—At Great Danes Hotel, Hollingbourne, Saturday, 9 December, 7.30 for 8 p.m., dinner and dance.●

MEDWAY AND GRAVESEND DIVISION.—At Bull Hotel, Rochester, Tuesday, 5 December, 8.30 p.m., medical films and discussion.

MIDLAND BRANCH.—At University Staff House, Edgbaston, Wednesday, 6 December, 7 for 7.30 p.m., annual dinner, and B.M.A. lecture by Mr. G. B. Spenceley: "South Georgia" (exploration of an antarctic island, with coloured slides).●

NORTH DEVON DIVISION.—Thursday, 7 December, Mr. W. E. Strachan: "Intercranial Haemorrhage."

NORTHERN IRELAND BRANCH.—At Park Avenue Hotel, Holywood Road, Belfast, Thursday, 7 December, 8 for 8.30 p.m., annual dinner dance. Guests are invited.●

NORTH MIDDLESEX DIVISION.—At Committee Room, North Middlesex Hospital, Tuesday, 5 December, 8.30 p.m., wine tasting.●

NORTH NORTHUMBERLAND DIVISION.—At Berwick Infirmary, Tuesday, 5 December, 8.30 p.m., address by Mr. E. L. Farquharson.

READING DIVISION.—At Library, Royal Berkshire Hospital, Wednesday, 6 December, 8.30 p.m., Professor R. B. Duthie: "Musculo-Skeletal Pain" (illustrated).

REDBRIDGE AND STRATFORD DIVISION.—At King George's Hospital, Ilford, Tuesday, 5 December, 8.45 p.m., meeting with Ilford Medical Society. Sir Ronald Tunbridge: "Fashion, Fact or Fiction."

ROCHDALE DIVISION.—At New Outpatient Hall, Rochdale Infirmary, Saturday, 9 December, 7 for 7.45 p.m., annual dinner.●

SALISBURY DIVISION.—At Medical Centre, Salisbury Infirmary, Tuesday, 5 December, 8 p.m., symposium: "Wives' Eye View." (Preceded by buffet supper.)

SCARBOROUGH DIVISION.—At Grand Hotel, Saturday, 9 December, 7.45 for 8.15 p.m., annual dinner.

SCUNTHORPE DIVISION.—At Wortley Hotel, Thursday, 7 December, 7.30 for 8 p.m., annual dinner dance.●

SOUTH BEDFORDSHIRE DIVISION.—At Biscot Mill Hotel, Wednesday, 6 December, 8 p.m., annual general meeting (followed by supper).●

SOUTH STAFFS DIVISION.—At Mount Hotel, Tattenhall Wood, Wolverhampton, Wednesday, 6 December, 7.30 for 8 p.m., supper meeting. Mr. C. Jones (editor of *Express and Star*): "The Press Council."●

STIRLING BRANCH.—At Allan Water Hotel, Bridge of Allan, Wednesday, 6 December, annual dinner and dance.

TORQUAY DIVISION.—At Sun Lounge, Victoria Hotel, Thursday, 7 December, 8.30 p.m., meeting to elect representatives to Annual Representative Meeting followed by B.M.A. lecture by Mr. G. Gorer: "Death, Grief and Mourning—an anthropologist's approach." Preceded by informal dinner, 6.45 for 7 p.m.●

WAKEFIELD, PONTEFRAC T AND CASTLEFORD DIVISION.—At Holmfild House, Wakefield, Wednesday, 6 December, 8 p.m., B.M.A. dinner-lecture by Mr. A. Dickson Wright.

WALTHAM FOREST DIVISION.—At Medical Education Centre, Whipps Cross Hospital, Wednesday, 6 December, 8.30 p.m., Dr. R. S. Francis: "Mycobacteria versus Mankind." (Preceded, 8 p.m., by meeting to elect representatives to Representative Body). Guests are invited.

● Branch and Division Officers Elected

BARNET DIVISION.—Chairman, Dr. R. Clark. Joint Honorary Secretaries, Dr. J. H. Muende, Dr. P. Clark. Honorary Treasurer, Dr. J. H. Muende.

BRISTOL DIVISION.—Chairman, Dr. T. G. F. Hudson. Vice-chairman, Mr. J. Angell James. Chairman-elect, Dr. K. C. P. Smith. Honorary Secretary, Dr. A. J. G. Dickens. Assistant Honorary Secretary, Dr. D. C. Jeffery. Honorary Treasurer, Dr. W. Woolley.

DERBY DIVISION.—Chairman, Dr. K. Gurling. Chairman-elect and Vice-chairman, Dr. D. H. Rhind. Honorary Secretary and Treasurer, Dr. R. A. A. Lawrence. Assistant Honorary Secretary, Dr. J. B. S. Morgan.

British Medical Association Proceedings of Council

The Association is likely to have a deficit of £20,000 on its budget for 1968. The inevitable rise in costs increased expenditure at a rate of about £20,000 a year, said the Treasurer, and the deficit in 1969 might well be £42,000. The Finance Committee proposed that the Representative Body should be recommended to increase the subscription in 1970. The Council would not agree on a date for raising the subscription until the Organization and Journal Committees had been consulted. Meanwhile B.M.A. Divisions are to be told what decisions of the Representative Body could not be implemented without heavy cost.

The Minister of Health is to be asked to discuss his proposals for studying the administrative structure of the medical services. A B.M.A. working party is to correlate the views of the standing committees on how to bring the Porritt Committee's report "up to date," and the Welsh Committee's report on a scheme for area health boards in Wales is to be published in January. Professor Henry Miller, chairman of the B.M.A.'s Planning Unit, outlined to the Council how the Unit intended to proceed. A resolution of the Representative Meeting in 1967 instructing the Council to "use whatever method it chooses to prepare an alternative Health Service" was referred to a panel under the chairmanship of Dr. I. M. Jones. It is to have £2,250 to analyse the economics of different ways of organizing medical care. It will give an interim report in 1968 and a full report in 1969.

Public health medical officers have received a firm offer in reply to their salary claims and the Public Health Committee considers it acceptable, but its recommendation that doctors should no longer be asked not to apply for local health authority appointments was amended by adding the words: "provided the Management Side of Committee C agrees that the revised salary scales are operated from 1 October 1966 and that note 3 of paragraph 2 of the appendix to the draft circular be deleted." The Council decided that public health service appointments should continue to appear in the "Important Notice" in the B.M.J.

A meeting of the Council of the Association was held on 29 November. Dr. RONALD GIBSON was in the chair.

The Council received with acclamation a report that LORD ADRIAN, a Gold Medallist of the B.M.A., had been elected Chancellor of the University of Cambridge.

The CHAIRMAN referred with regret to the death of Dr. R. HALE-WHITE, a member of Council from 1948 to 1957. A tribute to Dr. Hale-White was paid by Dr. C. M. SCOTT.

Administrative Structure of N.H.S.

The CHAIRMAN drew the Council's attention to a statement in Parliament by the Minister of Health on 6 November that he was reviewing the administrative structure of the medical and related services (*B.M.J.*, 11 November, p. 367). The Chairman suggested that the Minister's statement might be considered in conjunction with the report on area health boards from the Association's Welsh Committee.

The Minister had announced, said the Chairman, that he had begun a full examination of the administrative structure of the medical services that was needed not only for today but for ten to twenty years ahead. His studies would relate entirely to the administrative pattern. He would not consider the possibility of what would amount to an alternative health service, as had sometimes been suggested, involving, for instance, "a switch in financing from the public to the private sector." The Minister said he would aim in due course, but not for some months, to set out his views as a basis for public discussion and wide consultation. Only after that would the Government introduce legislation, if it were necessary.

The Minister had said that he had told the Royal Commission on Local Government in England and the Seebohm Committee, which was considering the local authority and allied personal social services in England and Wales, that he aimed to have proposals about the administration of medical and related services ready to be looked at alongside their own recommendations. He had also informed the Royal Commission on Medical Education, and he would be keeping in touch with the forthcoming reorganization of local government in Wales.

In reply to Dr. J. S. NOBLE, Dr. D. P. STEVENSON, the Secretary, said that on 21 December 1966 he had informed the Minister of Health of the following resolution of the Council of the B.M.A.: "Council believes that the present method of financing and organizing medical care in Great Britain requires re-examination and reassessment in the best interests of the community, and that it is of the opinion that the Government should be requested to set up immediately an independent inquiry into the finance, administration, and staffing of the National Health Service." The Minister had replied that he had noted the Council's views, which would receive consideration.

Welsh Committee's Views

Dr. A. WESLEY HILL said that the Welsh Committee had received with dismay the Council's decision to refer to the standing committees yet again the Welsh Committee's report on area health boards before allowing it to be published. Those committees had already commented, and their comments had been incorporated in the report. "We cannot go on sending it back in a never-ending process of this kind," said Dr. Wesley Hill. Now that the Minister of Health was about to stimulate discussion on future reforms of the N.H.S., there was a danger that the Welsh report on area health boards would be published too late for the B.M.A. to receive any credit for having itself provoked discussions on those matters.

Dr. Wesley Hill emphasized that the report was on only a pilot scheme applicable to Wales. The Welsh Committee, he said, thought it important that there should be no delay in the publication of its report beyond the meeting of the Council on 10 January, and it therefore recommended that the standing committees should be asked to forward their further views on the report to the Welsh Committee not later than 20 December.

Dr. A. SKENE said there was not much time, and it was probably true that the B.M.A. had no firm policy on the administration and organization of the National Health Service. As a matter of urgency, he suggested that the autonomous committees must grapple with the problem at the earliest opportunity, and that in the light of their views the Council might be able to make some informed representations to the Minister on this matter—a matter which

might concern legislation affecting the practice of medicine in this country for many years.

Dr. R. B. L. RIDGE suggested that before taking any decision the Council should consider why the Minister had made his statement now, when he could have made it any time in the past 20 years. The answer might well be because the Royal Commission and the Seeborn Committee were at work. "If the Minister uses the opportunity to play off the report of one of these bodies against the other, and the Welsh Committee is relying on Ministerial action to forward its particular case, then we may in fact be bogged down worse than ever."

Dr. A. V. RUSSELL said it was difficult to see why the Welsh Committee's report on area health boards should not be published forthwith. Dr. C. C. LUTTON thought that surely it was right that the B.M.A. should attempt to influence the Minister's thinking. The report on area health boards should be published now.

Need for Further Study

Mr. H. H. LANGSTON, Chairman of the Central Committee for Hospital Medical Services, said it would be a mistake to publish the Welsh Committee's report now. It contained matters which his Committee was unhappy about and would wish to study further. The concept of hospital management committees as they were at present constituted was in question, and there were other aspects of the hospital service which were under active consideration. If the report were published as a B.M.A. document the feeling in certain circles would be that the Association was a long way behind in its thinking.

Dr. JOAN CHAPPELL thought that doctors would be encouraged to put forward ideas now that there was a possibility of Parliamentary time being available to consider reforms in the N.H.S. Dr. C. P. WALLACE expressed the view that the Welsh Committee's recommendation that standing committees be asked to give their views on the area health board report not later than three weeks before the date of the January Council meeting was reasonable.

Dr. S. WAND, Treasurer, said that the Association should welcome the Minister's inquiry as a sequel to the Porritt Committee's report. The proposals on administration in the Porritt report could be brought up to date, and that could be done while the Minister was doing his review. When the Minister's paper was published the Council could debate it with up-to-date knowledge. Dr. J. L. MCCALLUM pointed out that for the first time the Association had been first in the field and ahead of the Ministry by some five to six years.

Dr. SKENE suggested that the Welsh Committee's report on area health boards might prove, after full discussion by the autonomous committees, not to be the sort of lead that the B.M.A. on mature reflection would wish to give. The fact that the Minister had said he would produce a paper was not an indication for the Association to panic and to take precipitate action.

The CHAIRMAN suggested that the Council might consider the following courses of action. Firstly, the Minister should be asked for immediate consultation on his statement, and that the Association might be brought in

on any policy which he proposed to set out in his paper. Secondly, that a working party should be set up to bring the report of the Porritt Committee up to date and to correlate the views of the standing committees. Thirdly, that the Association's views on area health boards, as submitted by the Welsh Committee and commented on by the standing committees, be published for discussion in January.

Dr. J. E. MILLER said he thought it would be better for the Welsh Committee's report on area health boards to be published before discussions were held with the Minister. Dr. I. M. JONES agreed with Dr. Miller. He also suggested that the Council should support the Minister in asking for an inquiry, but, at the same time, should insist that it was not the usual type of interdepartmental inquiry. It should be an inquiry conducted by a completely independent and authoritative body.

Dr. J. S. ROSS said it was important that the medical profession should consult the Minister forthwith to find out what was really in his mind, and, at the same time, feed into him certain ideas which it was hoped he would accept. Once the Minister had published his paper it would be more difficult to shift him away from his proposals, even though they might be only for discussion.

Demand for Inquiry

Dr. NOBLE moved and Dr. Jones seconded: "That the Council welcomes the decision of the Minister to study the administration of the National Health Service. It is, however, concerned at the mode of approach outlined by the Minister and repeats its demand for an inquiry to cover the whole field of finance and administration of the National Health Service, and that

it be considered by an independent body."

Dr. Noble said that after twenty years the N.H.S. was ripe for a full inquiry. The profession, in the last year or two, had come near to having more clear ideas on what the Health Service might look like in the future. He believed that the financing of the N.H.S. could not be separated from its administration. Dr. A. N. MATTHIAS, Chairman of the Representative Body, supported the motion. He said that the Minister's reference only to administration was a clear negation of the resolution which was passed by the Council in 1966.

Dr. STEVENSON pointed out that there was a risk that an independent inquiry would not be by a body of doctors. It would be an inquiry in which the point of view of doctors would play a minor part, because it was an administrative rather than a clinical matter. Also an independent inquiry would probably take two years. In Dr. Stevenson's view it would be preferable to see the Minister first and to ask for a discussion on all the relevant matters.

Dr. R. COVE-SMITH and Mr. LANGSTON supported Dr. Stevenson.

The motion was lost.

The Council finally agreed that the Minister should be asked for an opportunity for representatives of the profession to discuss his proposals with him. It was also agreed that a working party should be appointed to bring the report of the Porritt Committee up to date and to correlate the views of the standing committees. The members of the working party would be appointed by the Chairman of Council in consultation with the three standing committees. It was agreed, thirdly, that in January the considered views on area health boards submitted by the Welsh Committee and commented on by the standing committees should be published for discussion.

Association's Finances

Dr. S. WAND presented the report of the Finance Committee and drew the Council's attention to the financial situation of the Association. The recent devaluation of the currency had greatly affected the B.M.A.'s budget for 1968. It was expected that devaluation would increase the deficit on the Secretariat's budget by £8,000, making a total deficit of £20,000 for 1968.

Each year, said Dr. Wand, because of the inevitable rise in cost of essential services, the Association's expenditure increased. Based on experience in the past it was estimated that the deficit of £20,000 in 1968 might well become £42,000 in 1969. The Finance Committee felt strongly that much greater regard must be paid by the Representative Body to the costs of carrying out some of its resolutions.

Proposals for Subscription Increases

The Finance Committee had considered the view of the General Purposes Committee that an increase in subscription rates had become inevitable, and that a recommendation should be made to the Representative Body in 1968. The Finance Committee concurred that an increase was inevitable, but had serious reservations on its timing. The full effects of devaluation would not be known until the latter part of 1968. It was

desirable that members should know of the Association's worsening financial position and be given ample warning of Council's intentions. It was also right that the Council should have an opportunity of re-examining current expenditure before going forward with specific proposals for an increase in subscription rates. For those reasons the Finance Committee was unanimously of the opinion that 1969 would be the right time to make firm proposals to the Representative Body for an increase in the subscription.

The Finance Committee proposed that a recommendation should be submitted to the Representative Body in 1969 for an increase in the membership subscription rates to take effect on 1 January 1970, and that in drawing up the new scale of subscriptions particular consideration be given to those members paying the concessionary rates. It further proposed (1) that Divisions should be informed of the decisions of the Representative Body that could not be implemented without incurring heavy costs; and (2) that steps should be taken to inform members of the financial position and of the likelihood that the membership subscription might have to be increased.

Mr. LANGSTON asked why the Treasurer did not recommend an increase in subscriptions for 1969. Dr. RIDGE said he was concerned at the proposal to budget for a deficit. It

was apparent that there must inevitably be an economic blizzard. If the Association carried forward a growing deficit members would be faced not with a moderate increase in subscription in 1969 or 1970 but with a massive increase. To defer the increase for a year seemed to be a policy of despair.

Dr. WAND, in reply to Mr. Langston, said that the Finance Committee did not know yet how much more money the Association would want. To ask for an increase in subscription that would allow for the possible effects of devaluation and would avoid the need to ask for a further increase in another year or two would mean asking for a big increase. By 1970 a big increase might still be needed, but it would at least be done in one go.

Pay for Work Done

Dr. LUTTON maintained that the Association would have to spend more money in some sectors and less in others. It should spend more on information. It would have to decide what was essential activity. Members would pay according to what they saw was being done. The expansion of the Association's work had to go on, and it was up to each member of Council to ensure that the members in his area knew of the work being done in B.M.A. House. Dr. Lutton suggested that the subscription should be raised in 1969.

Dr. JONES supported the comment of the General Purposes Committee and opposed the recommendation of the Finance Committee to defer an increase in subscriptions till 1970. He recalled that on each of the last two occasions when the subscription was raised the Council had followed the policy being advocated by Dr. Wand. The Council had allowed the Association to go into the red before action was taken. By the time the new subscription rates came into effect there would be a substantial backlog to make up. No one could foresee the reaction of the Representative Body to any recommendation, but that did not excuse a failure to recommend what was clearly right. If the Representative Body were informed of all the facts and was assured that priority would be given to those Association activities which were concerned with direct service to its members it was doubtful, said Dr. Jones, whether its reaction would be very different in 1968 from what it would be in 1969.

Dr. R. P. HENDRY recalled that when the subscription had been increased from 4 to 6 guineas it had taken a long time before the United Kingdom membership recovered to what it had been before the increase. With a drop in membership there was also a loss of prestige. Full reasons must be given for any increase in subscriptions.

Dr. ROSS said that the Association was still not in a position in which the profession was as keenly behind it as it should be, and it was necessary to improve the information services. Furthermore, it had to be remembered that it was what the Association did that mattered. The individual doctor took the view that far too much money was spent on things that did not really matter. The Association's activities should be gone through with a fine toothcomb to see which things could be dispensed with in order to save money. The effects of devaluation could not be judged, and Dr. ROSS advised the Council to wait for a few months before

deciding to make a firm recommendation to the Representative Body next year to increase the subscription.

Dr. WALLACE supported the Treasurer's view. Dr. Wand was well aware of the repercussions that an increase in subscription might have, and there was much to be said for choosing the right moment.

Many members of the Association were ill-informed. But that was not the Council's fault. In Dr. Wallace's view it should call a halt to any increase in information services. "Many of us are suffering from having more information than we can digest," he added. "The B.M.A. is not a business organization. It is a scientific body with a medico-political side to it." In Dr. Wallace's opinion it was a mistake at the present juncture for Council to tie itself to a decision on what it would do the year after next.

Cut Costs

Dr. G. E. CRAWFORD asked whether the Finance Committee had considered sending a questionnaire to each member of the Association setting out the plain facts, and asking whether the member would prefer an increase in subscription now or a larger one later. Mr. G. E. MOLONEY said there was nothing wrong in expanding the B.M.A.'s activities, but now everybody had to cut their costs, including the B.M.A. Serious consideration had to be given to the question of raising subscriptions at a time when the periphery would expect it.

Dr. H. FIDLER suggested that the B.M.A. subscription was ridiculously low. Members were getting all the benefits of membership on the cheap. If the members were not aware of those hard facts they ought to be told. But if it were thought that no rise in subscription could be suggested in the near future Dr. Fidler suggested that consideration should be given to asking members whether they would be willing to pay a voluntary levy, because of the great change in the financial circumstances.

Dr. NOBLE stated that the membership drive was beginning to show results. Members would pay for service, and the Organization Committee had always held the view that the membership depended on the Association having positive policies and "propagating them with force." The Organization Committee thought that it would be disastrous to increase subscriptions unless greater efforts were made than at present to let the profession see that not only was the B.M.A. acting for it but was actively doing something for it. Dr. Noble pointed out that his Committee had not been informed of the recommendations of the Finance Committee, and he moved the reference back of those recommendations.

Dr. A. C. HOUGHTON said that, in his view, members at the periphery really had very little out of the B.M.A. It was necessary to keep a very careful watch on expenditure. Dr. CATHERINE GRAY said it was essential for members to know why the subscription was being increased. There was a belief that money was rather wasted at Headquarters. Members did not understand what the money was used for, and it would be impressive if they knew that Headquarters was trying to effect some economies. For instance, though the amount involved would be small, Dr. Gray suggested that members

of the Council, of the Representative Body, and of committees might perhaps be refunded only second-class railway fares.

Economies First

Dr. A. M. RANKIN suggested that it would be bordering on madness to increase the subscription. Every member he had spoken to on the subject considered that 12 guineas was about the limit to which they would go. It was clear that the subscription would need to go up at least to 20 guineas, and members would not be willing to pay that. The Association had not been able to get for general practitioners all that had been hoped for. Hospital junior staff were in a state of revolt, and provincial consultants would be the next. In Dr. Rankin's view any increase in subscription now would lead to a great loss of members. The Association would be weakened, and, since it was the only body which negotiated with the Government, the whole profession would suffer. He was opposed to any increase in the subscription until such time as economies which had been suggested from time to time had been effected.

Dr. J. M. DUNLOP suggested that subscriptions to the Defence Trusts should be compulsory and be part of the Association's annual subscription. Shortly there was likely to be an increase in the retaining fee of the General Medical Council, and it might be possible to add that fee to the annual subscription to the B.M.A., and the B.M.A. could then take over the G.M.C. That would then mean 100% membership of the B.M.A.

Dr. R. E. W. OLIVER said that the subscription should be increased, because psychologically it was the right time and members expected it to be increased, and because the Council should have enough confidence to decide what the Association's policy should be, to go out and sell it, and to make sure doctors realized that they were getting value for money.

Dr. WAND said that the Association had certain reserves which provided it with a substantial part of its income. Nevertheless, these were exceptional times and reserves were for use in exceptional times. It was important to let members know that events had overtaken the Association financially and that they must be prepared for some increase in subscription. Dr. Noble had made a valid point when he had said that the Organization Committee had not been consulted. Indeed, said Dr. Wand, the Journal Committee might have views on the subject. Therefore he suggested the following revised form of words for the Finance Committee's first recommendation: "That the Council supports that a recommendation be submitted to the Representative Body in 1969 for an increase in the membership subscription rates to take effect on 1 January 1970, and that in drawing up the new scale of subscriptions particular consideration be given to those members paying the concessionary rates, and that this be referred to the Organization Committee and to the Journal Committee for their consideration."

Dr. NOBLE accepted the revised wording of the recommendation, but Dr. RIDGE moved the reference back of Dr. Wand's revised recommendation. Mr. MOLONEY seconded the reference back.

Dr. RIDGE explained that he moved the

reference back on the ground that the Council was not satisfied that 1 January 1970 was the optimum date for the increase in the subscription.

The reference back was carried.

It was agreed that the recommendation should be sent to the Organization Committee and the Journal Committee for their expert opinion.

The second recommendation of the Finance

Committee, (1) That Divisions should be informed of the decisions of the Representative Body which could not be implemented without incurring heavy costs, and (2) that steps be taken to inform members of the financial position and of the likelihood that the membership subscription might well have to be increased, was adopted.

The report of the Finance Committee, duly amended, was adopted.

Planning Unit

The Council proceeded to consider a report prepared for the Planning Unit by its Working Party on Intensive Care, and a report on the activities of the Planning Unit.

The CHAIRMAN informed the Council that Professor Henry Miller, the Chairman of the Planning Unit, would be attending the meeting later in the day. The Unit was not prepared to come to any conclusions after a hurried and superficial investigation into the Health Service. The Unit's idea was, as he had explained to the G.M.S. Committee (*Supplement*, 2 December, p. 60), to go through its project brick by brick to build up the structure of a health service. The Unit had begun to study the question of primary medical care. The £10,000 set aside by the Association for planning included the cost of staffing the Unit.

The Chairman drew the Council's attention to the report of the General Purposes Committee, in which the particular position of the Advisory Panel under the chairmanship of Dr. I. M. Jones was pointed out. The Planning Unit had felt unable to accept Dr. Jones's Advisory Panel as an integral part of the Unit. It seemed to the General Purposes Committee that the Council might well consider it appropriate to refer the following resolution of the A.R.M., 1967, to Dr. Jones's Panel, but, in view of the present financial position, the Committee did not consider it would be justified in authorizing the additional sum of £2,250 asked for by Dr. Jones's Panel to carry out the task:

"That the results of the recent negotiation with the Ministry of Health have done little to alter the deficiencies of the National Health Service, the majority of which stem from the inadequate finance which is available at present, or will be available in the future from direct taxation. The Annual Representative Meeting instructs Council to use whatever method it chooses to prepare an alternative Health Service. That this alternative shall be presented with adequate time for discussion by the profession before the Annual Representative Meeting as soon as possible."

The General Purposes Committee recommended that the resolution be referred to Dr. Jones's Advisory Panel, but that he be asked to prepare an interim report for consideration by the Council and the Representative Body within the limits of the existing resources of the Association and without embarking on the economic research which was proposed.

Alternative Service

Dr. A. V. RUSSELL said that the Planning Unit had developed into something completely different from what had been envisaged by the Representative Body when it asked for something to take the place of the former Amending Acts Committee. The Unit seemed to be working in an extremely rarefied atmosphere, and many of its activities appeared

to be of an academic nature. There was no sense of urgency that could be detected. Furthermore, the Unit did not seem to be keen on the idea that Dr. Jones's Panel should get to work on what the Representative Body asked for as a matter of some urgency—namely, the framing of a desirable alternative medical service.

Dr. J. BENYON said he disagreed with the General Purposes Committee's recommendation. In his view every effort should be made to find the £2,250 required for Dr. Jones's Panel to get on with the job that most members of the Association imagined was being done. Dr. RIDGE suggested that it was extraordinary that the argument used by the Chairman of the Planning Unit, Professor Henry Miller, was that he could not take Dr. Jones's Panel under the Unit's umbrella because he (Professor Miller) did not have the opportunity of selecting the members of the Panel. The Council had been responsible for setting up the Unit, but it had not had an opportunity of expressing an opinion on Professor Miller's appointment nor on the members of the Unit which he had selected.

Dr. MARY ESSLEMONT pointed out that though there was one woman doctor on the Unit there did not appear to be any women doctors on the working parties it had set up. According to the report on the activities of the Unit, B.M.A. Divisions and Branches had been invited to nominate one of their younger doctors who had a special interest in "looking ahead" to act as liaison officer with the Planning Unit. Dr. Esslemont said she had no knowledge of any such invitation being received in her area. Referring to the Unit's report on intensive care, Dr. Esslemont suggested it was lamentable that such a report should be produced when there were other more important basic problems to be dealt with.

Dr. W. H. N. ANGUS asked what was meant by an "alternative service." Did it mean the eclipse of the N.H.S. and its replacement by a private service, or did it mean an alternative National Health Service? If it meant the former then Dr. Jones's Panel was probably the right body to look into it. If it meant an alternative National Health Service, differently financed and differently administered, then he could understand Professor Miller's objection to Dr. Jones's Panel going beyond a certain limit.

Fogging the Issue

Dr. NOBLE referred to the report on Intensive Care, and said it did the Association great credit. At the same time the Planning Unit was proceeding with other matters. The Council would fog the issue if it criticized either Dr. Jones or Professor Miller. The Association could gain something from Dr. Jones's Panel and from Professor Miller's

Unit. "If this Association instead of looking at this narrowly looks at it in a big way, we can do a great deal of good for British medicine," Dr. Noble said. "I hope Council will ensure that both units continue to carry out the wish of the Representative Body."

Dr. C. M. SCOTT suggested that the type of thing coming from the Planning Unit was not the real bread-and-butter stuff that the Association hoped to see. The Unit, though undoubtedly first-class, would not produce the type of report that the general practitioners wanted.

Dr. G. R. OUTWIN supported Dr. Noble and refuted the comments made by Dr. Mary Esslemont about the report on intensive care. It was important that some authoritative document should be published at a time when so few hospitals were being built.

Dr. WALLACE said that he had no doubt that the Guildford Division, from whom the resolution emanated, meant an "altered" National Health Service. The Guildford Division was aware that the National Health Service brought into being in 1948 was based on a set of circumstances that existed in 1930, and that since then the affluent society had arrived. In his view the matter would be best answered by having a report from Dr. Jones's Panel. Dr. Wallace said he supported the recommendation of the General Purposes Committee.

Dr. OLIVER said it would seem that two planning units were required, one to deal with the scientific and the other the political work. Professor Miller's Unit could look after the scientific aspect and Dr. Jones's Panel could look after the medico-political.

Dr. J. C. CAMERON, Chairman of the General Medical Services Committee, said that Dr. Jones had set up his panel in good faith, and the Council should not hamstring him in the work he had set out to do. The G.M.S. Committee had considered the Planning Unit's intention to study the future of primary medical care. Dr. Cameron pointed out that the reports of the Planning Unit would gain currency throughout the profession as being Association policy. That, in his view, was a danger.

When it came to medico-politics the Council should consider carefully whether it was right that reports from a source within the B.M.A. should be published independently. Professor Miller had insisted on the Planning Unit's right to publish its own reports.

Dr. W. T. COOKE said that the report on intensive care was in his view a first-class document. It could be used throughout the hospital service as a far-seeing report. The problem over the next 10 years would be a shortage of doctors, and it was necessary to get the facts. He did not believe that by assessing the existing position it was possible to project into the future, but it was absolutely necessary to have the facts.

Dr. SKENE drew the Council's attention to the following paragraph contained in Appendix IV of the report on the activities of the Planning Unit:

W. S. Lewin said that the Planning Unit, if it was to have any impact, must come to terms with itself. In his view, in the last analysis the really powerful voice to which the Minister would listen would be a powerful independent body, especially if it was seen to have the support of the standing committees. He suggested that if the various working parties of the Planning Unit were to go to the appropriate standing

committees for help and advice then the confidence of these bodies in the Planning Unit would be established.

Dr. CRAWFORD said that if the Planning Unit was to be of any use it must be completely independent, and it was up to Council to point out where it went wrong if it did go wrong.

Professor Henry Miller

At this point the CHAIRMAN introduced Professor Henry Miller to the Council, and invited him to present the Planning Unit's report on intensive care and to speak on the work of his Unit.

Professor HENRY MILLER said that the Council would probably be surprised that the first report of the Unit was on intensive care. The reason why the first two or three reports would be on particular aspects of medical services rather than on major issues was that to offer any worth-while observations on major problems would require the collection of information, the sounding of opinion, and much organization and deliberation. The Unit therefore thought it wise to sharpen its operational teeth on a number of matters which, though not major issues, were of urgency to the Health Service. Intensive care was a good example. Almost all hospital management committees and boards were under pressure to establish intensive-care units, and they could do that on their existing budgets only by depriving their hospitals of some other service. The report was designed to deal with a pressing and urgent situation in furnishing what the Unit believed to be expert advice.

Professor Miller said he did not wish the Council to think that the Unit's efforts would be limited to purely technical matters. A working party was being established to examine the use of computers in medicine. Most people concerned with the employment of computers in medicine were keen that the B.M.A. should undertake a study. It was a topical problem which gave the Unit an opportunity to present something useful while its wheels ground more slowly over issues in which it was more interested—namely, what would happen to general practice, how the hospitals would be organized, and how the kind of hospital that was needed would be provided.

Professor Miller said that the problems of general practice were not specifically problems of the National Health Service. It would be a mistake to call the Unit's working party a working party on general practice. What the Unit was really concerned with was how the need for doctors was to be met. It had to look at various possible ways in which the need could be met and examine their advantages and disadvantages. Professor Miller hoped that it would be possible to collect evidence and to arrange for the conduct of experiments on primary medical care on a modest basis before producing a report.

Association Policy

Dr. SKENE said there was an overlap between the scientific and medico-political fields, and he asked Professor Miller how the Planning Unit, when it entered the medico-political field, would acquaint itself with Association policy in order to avoid publishing a report which might be at variance with established policy.

Professor MILLER replied that the medical members of the Planning Unit were fairly well acquainted with B.M.A. policy. But there were many instances when the Unit would wish to consult the appropriate B.M.A. committee or to submit drafts of the Unit's reports for amendment and comment.

Dr. WALLACE asked whether it would be possible to devise a way for the Council to see the Unit's reports and for commenting on them before publication. The report on intensive care, for instance, was issued as a B.M.A. publication, which meant that the Council must inevitably take some responsibility for it.

Professor MILLER said he was sure that the Unit would be delighted if the Council or committees of the Association debated draft reports of the Unit and made suggestions.

Mr. MOLONEY congratulated the Planning Unit on its report on intensive care. He asked Professor Miller how far he thought the Unit's activities should spread.

Professor MILLER replied that the Planning Unit regularly discussed possible projects. A number of things which the Unit would like to investigate were really beyond the scope of a predominantly professional working party. The Planning Unit itself held a series of meetings on a subject, interviewed people in the field concerned, and tried to get a picture of the type of brief it wished to give to a working party. It then selected the chairman of the working party. The technology of the exercise was carried out by the working party, and it furnished draft reports which were discussed by the Planning Unit. As to the range of subjects covered, it was obviously impossible to cover them all, and only the major subjects could be dealt with. Of those, the first was to be the provision of primary medical care and the second hospital staffing.

In answer to Dr. WESLEY HILL, who asked how the Unit defined the problems in general practice, Professor MILLER said that, as the Dean of a Medical School, one problem he thought arose was the ever-decreasing inclination on the part of medical students to choose general practice. Most of the vocal discontent within the profession came from general practitioners. There were many countries where that situation had progressed to the point where general practice, as it was known in this country, had virtually closed down.

Dr. JOAN CHAPPELL said that the Council was under pressure to provide plans for an alternative N.H.S. It would be useful if Professor Miller could give some idea of the Unit's programme in that connexion.

Professor MILLER said that either the Unit should look at the whole situation and make a general statement or it should divide the problem up. A study of primary medical care was almost bound to bring up questions concerning the organization of the Health Service as a whole, and it was doubtful whether anything worth producing would be produced before another year at the earliest.

Critical Approach

Dr. J. H. LANKESTER suggested that any analysis of general practice should be based on how it was possible to stop existing general practice from degenerating. Professor MILLER said that the Planning Unit did not regard itself as setting out to find evidence to

support either the existing organization of general practice or any potential organization. It set out to look at it critically to see where it could be improved or where it could be maintained. It would be foolish to think there was no alternative to the existing arrangement.

Dr. C. J. BOLT asked Professor Miller whether he felt that young doctors should be represented on all the working parties, and, if so, what steps had he taken to ensure that. Professor MILLER agreed with emphasis that at least half the members should be under 35, and he would try to achieve that.

Dr. RIDGE said he noted that the Planning Unit did not consider that what was called for in the A.R.M. resolution (producing plans for an alternative Health Service) was properly within its terms of reference. It had become apparent in the Council's debate that the significance of the term "alternative" was related to an alternative within the National Health Service itself. In the light of that, Dr. Ridge wondered whether Professor Miller thought there was any possibility of his Unit modifying its attitude.

Professor MILLER said he did not think that the Unit was in a position to produce plans for an alternative health service, because there were obviously many alternatives which ought to be considered. It would be a formidable task. They seemed to be rather political considerations.

Dr. OUTWIN asked Professor Miller what his reaction would be if a working party voicing the views of the Association produced a report in advance of and in conflict with a corresponding report from the Planning Unit. Would the Unit produce its report, would it withdraw it, or modify it, or what?

Professor MILLER replied that there was room for a considerable difference of opinion, and if it assisted in reaching the truth it was to be welcomed. It seemed to him that if there were a conflict between the two planning units it would reflect a conflict which existed in the profession.

Dr. NOBLE said that the Planning Unit was supported by the profession, which was very interested in what it was doing. He asked whether the Unit had considered any means by which it could improve its public relations within the profession.

Professor MILLER agreed that the Unit should do more to publicize its activities.

A vote of thanks to Professor Miller for attending the meeting and for replying to questions was carried by acclamation, and Professor Miller then withdrew.

Money for Job

Dr. RIDGE reminded the Council that the remit to Dr. Jones's panel was primarily medico-political. It was essential that it should be done properly, and Dr. Ridge wanted to know whether that was possible without additional expenditure.

Dr. JONES said it was not impossible to provide an interim report, for which the General Purposes Committee asked, but his Panel was unanimous that it could not do its job properly without, as set out in the report, analysing (1) the economic basis of the National Health Service and the reasons for its failure to raise sufficient finance to provide medical care at the standards required to satisfy rising expectations; (2) public and consumer expenditure and the possibilities of

providing more money from taxation and/or consumer expenditure; (3) the merits and defects of private medical care and insurance in North America and their lessons for Great Britain; and (4) private medical care and health insurance and the merits and defects of systems of organizing and financing medical care in Europe and Australasia, and their significance for Great Britain.

It was proposed to remit each of these tasks, each one costing approximately £500, to an expert who, with the help of others, would produce a report to be considered by the panel. The A.R.M. resolution could not be properly carried out unless those exercises were carried out. If the Council granted the money it could expect that the final analysis would be available to the Panel in the autumn of 1968, and that the Panel would complete its report for the Council before the Annual Representative Meeting of 1969.

Dr. OUTWIN moved: "That such is the urgency of the implementation of the A.R.M. resolution submitted by the Guildford Division that the Council authorizes the provision of £2,250 requested by Dr. Jones in order that his Panel may undertake this work, and produce an interim report in 1968 and a complete report in 1969."

Dr. WAND pointed out that in the budget for 1967 some £4,000 was provided for the Planning Unit. For 1968 £9,000 was provided, and it was expected to cover all that was to be done in the way of planning. The Finance and the General Purposes Committee had decided that Dr. Jones and his Panel should try, within the limits of the budget and with the resources available in B.M.A. House, to provide an answer to the A.R.M. resolution. At the moment the Association had not the extra money. "If I am to be asked continually for money in this fashion I cannot see how it is possible for me to continue to try to manage the affairs of the Association," Dr. Wand concluded.

The CHAIRMAN asked Dr. Jones whether it was absolutely necessary to have four experts at work. Dr. WALLACE asked whether it was seriously being suggested that the Representative Body should be informed that its project was to be postponed or carried out in a second rate manner for the sake of some £2,000. Dr. JONES said he would do whatever Council instructed him to do to the best of his ability. But he could not withdraw his request that the money should be made available to his panel. He pointed out that the Treasurer had not taken exception to the motion at the Representative Meeting, and the Representative Body had every reason to believe that the money would be forthcoming.

A motion that the question be now put was carried, and Dr. Outwin's motion was put to the meeting and carried.

Public Health Service Appointments

Dr. J. M. DUNLOP moved: "That the Chairman of the Central Ethical Committee be invited to look into the advisability of ensuring that immediately the present ban is lifted all authorities which have defied the ban of the British Medical Guild (Surrey, Tees-side, etc.) be permanently named in the 'Important Notice' which appears each week in the *British Medical Journal*."

Dr. WALLACE said he had the gravest doubts about the motion. There had been a settlement, and he wondered whether it was

wise, in the light of a settlement, to carry on as if the Association was still half at war.

Dr. H. L. LEAMING said the motion would militate against Tees-side recruiting staff of good quality in the future. Dr. Ross urged Council to reject the motion.

Dr. DUNLOP pointed out that if the invitation were not so given to the Chairman of the Central Ethical Committee there would be no point in having a ban in the future.

The motion was carried by 18 votes to 16 votes.

At this point Dr. Gibson left the meeting and Dr. Wand took the chair.

Public Health Committee

Dr. C. METCALFE BROWN presented the report of the Public Health Committee.

He said that a firm offer had been received from the Management Side of Committee C in reply to the Staff Side's claim for an increase in the salaries of public health medical officers submitted to the Management Side in June 1966. While the offer was not entirely satisfactory, the Committee believed that in the existing economic climate it was extremely unlikely that any further concessions would be gained. In the circumstances the Committee thought the offer represented an acceptable basis for the conclusion of negotiations.

The Public Health Committee therefore recommended that (1) the British Medical Guild be asked to withdraw its recommendation to doctors not to apply for local authority public health appointments; (2) the public health service be withdrawn from the "Important Notice" in the *British Medical Journal*; and (3) the *British Medical Journal* be empowered to accept advertisements for local authority public health appointments forthwith.

Dr. Metcalfe Brown expressed gratitude to the Council for its strong and prolonged support for the public health medical officers, and to the *British Medical Journal* for its co-operation. The CHAIRMAN congratulated the Public Health Committee on what it had achieved.

Dr. DUNLOP moved by way of amendment to add to recommendation (1) the words "provided the Management Side of Committee C agrees that the revised salary scales are operated from 1 October 1966 and that note 3 of paragraph 2 of the appendix to the draft circular be deleted."* Dr. G. N. MARSH seconded the amendment.

Dr. DUNLOP said that before the ban was lifted it was necessary to get a quid pro quo from the Management Side. The ban had been very effective, and though he agreed that the time had come to remove it it should not be removed without gaining some concession from the Management Side. He reminded the Council that the claim had been submitted to the Management Side on 16 June 1966, a month before the Government's pay freeze.

Dr. METCALFE BROWN assured the Council that the Committee had fought to achieve the date 1 October instead of 1 February in the

*Note 3 of the draft agreement on revised salaries for public health medical officers, which was before the Council, stated that, "Save in exceptional circumstances the maximum salary of any post in the range [the proposed new upper salary range and assimilation points for senior medical officers] must be below the maximum salary prescribed by Committee C for the deputy medical officer of health of the same employing authority. This provision shall be subject to review in the light of experience."

offer. However, the Management Side had not agreed and there had been no support from the Ministry of Health. The Public Health Committee by a clear majority considered that 1 February would have to be accepted as the date.

The amendment was carried.

The Public Health Committee's second recommendation, that the Public Health Service be withdrawn from the "Important Notice" in the *British Medical Journal*, was not accepted.

The CHAIRMAN ruled that the Committee's third recommendation fell to the ground.

The report of the Committee, as amended, was adopted.

Medicines Legislation

Dr. SKENE presented the report of the *Ad Hoc* Committee on Medicines Legislation. He recommended that the memorandum prepared by the Committee be approved and forwarded to the Ministry of Health, and that a deputation be appointed to visit the Ministry for discussions on 5 December.

Dr. Skene drew particular attention to the following paragraph in the memorandum: "The Association is not in accord with the statement in the White Paper (para. 25) that 'licensing will rest with the Health and Agriculture Ministers' and would go further than the Sainsbury Report (para. 337) 'on the licensing function it is probable that the Commission will be advisory only.' The Association is of the view that for authority for licensing to be vested in an independent Medicines Commission with executive powers would be the most desirable mechanism for licensing. Whatever the arrangements for licensing may ultimately be, we regard it as imperative that an adequate appeals machinery, independent of the licensing authority, should be established."

Dr. CAMERON said that the G.M.S. Committee had considered the White Paper on forthcoming legislation on the safety, quality, and description of drugs and medicines in conjunction with the Sainsbury Report and the letter on the subject from the Ministry of Health, dated 20 October, which was reported to the last meeting of the Council. The Committee was seriously concerned that the White Paper envisaged very wide powers being given to Ministers in both the licensing of drugs and medicines and the vetting of preparations for efficacy, toxicity, and safety.

The G.M.S. Committee had noted that the Sainsbury Report proposed that the vetting of new preparations should be the responsibility of an independent Medicines Commission, and it would support that view provided that the Commission was truly independent with executive powers and not constituted on the lines proposed in the White Paper for a Commission to advise Ministers.

The White Paper intended that the Commission should be kept "to a reasonable size," but in the appointment of its members the Ministers would consult 20 or more professional organizations. Only one nominee of the B.M.A., or two at the most, could be expected to be appointed to the Commission, and the G.M.S. Committee was alarmed at the prospect of an inadequate representation of general practitioners to protect their vital interest in prescribing for their patients.

Dr. Cameron registered a protest that the G.M.S. Committee had been hurried in the

matter. More opportunity should have been given to make its views known.

Dr. SKENE said that a protest concerning the shortness of time had already been made to the Ministry with some effect. The *Ad Hoc* Committee had also made the point concerning the independence of the Medicines Commission. The matter of representation of the Association on the Commission was a valid point and should be raised with the Ministry.

Dr. CAMERON said his Committee would wish to seek from the Minister a renewed assurance that there was no intention in any way to limit the freedom of general practitioners to prescribe under the N.H.S.

Dr. J. S. HAPPEL said it was fundamental to the whole practice of medicine that the Medicines Commission should be independent.

Dr. CAMERON moved that the word "desirable" in the paragraph referred to by Dr. Skene should be deleted, and that the word "essential" be substituted for it.

Dr. RIDGE seconded the amendment, which was carried.

The recommendations of the *Ad Hoc* Committee were adopted, and the Council agreed that the deputation to see the Minister should consist of the Chairman of Council, Dr. Skene, Dr. Ridge, Dr. G. Owen Williams, and Sir John Richardson, Chairman of the Joint Consultants Committee.

Junior Hospital Doctors' Association

The Council had before it a memorandum on the representation of hospital junior staff submitted by the national executive council of the Junior Hospital Doctors' Association.

Dr. BOLT suggested that the memorandum might be referred to a small committee set

up by the Council. Dr. SKENE said it would be wrong for Council to set up a working party in anticipation of the views of the Central Committee for Hospital Medical Services and of the Hospital Junior Staffs Group Council.

Dr. NOBLE suggested, and it was agreed, that the memorandum should be sent to the Central Committee for Hospital Medical Services, to the Hospital Junior Staffs Group Council, and to the Organization Committee.

Hospital Medical Services

Dr. SKENE presented the report of the Central Committee for Hospital Medical Services in the absence of its Chairman, Mr. H. H. LANGSTON.

Ballot on Distinction Awards

Dr. RANKIN asked why it had taken 12 months to organize the ballot on distinction awards, and, secondly, why some ballot papers did not reach all consultants who were members of the Association.

Dr. SKENE replied that Headquarters did not have lists of members of the Association by category or professional activity, and it was dependent on regional hospital boards to give the names of consultants in the N.H.S. There were many consultants who were serving as honorary consultants on the staffs of universities.

Referring to the composition and terms of reference of the Negotiating Subcommittee, a matter which the Committee had under consideration, Dr. LEAMING moved that the Council should request that when considering the composition of the Negotiating Subcom-

mittee the Central Committee for Hospital Medical Services should take note of the desirability of ensuring that it contained adequate representation not only of hospital junior staff but also of consultants working exclusively in regional board hospitals.

The motion was carried.

Private Practice

Dr. I. M. JONES presented the report of the Private Practice Committee.

He referred to the Health Services and Public Health Bill (*B.M.J.*, 2 December, p. 562) and said it was clear that it was the intention of the Minister of Health to abolish completely all private beds in N.H.S. hospitals. That had the gravest implications for the freedom of the citizen as well as for the freedom of the medical profession, and in his view it was a direct breach of the undertakings given by the Government of the day to the presidents of the Royal Colleges before the National Health Service Act was passed. Dr. Jones asked for a search to be made to find out the exact nature of the undertakings given, and urged that the strongest possible protest be made on behalf of the Association to the Minister of Health.

The Council agreed with Dr. Jones's proposals.

Other Committees

The Council also considered the reports of the following: Alcohol and Road Accidents Committee, Annual Meetings Committee, Central Ethical Committee, Charities Committee, Committee on the Common Market, Film Committee, and General Medical Services Committee.

The meeting terminated at 8.40 p.m.

Private Practice Committee

The Committee agreed on the contents of a memorandum to the Council recommending what action the Association could take to extend private practice and to increase support for Independent Medical Services Ltd. Doubt was expressed about the soundness of the Central Ethical Committee's ruling that I.M.S. must not provide lists of names of I.M.S. doctors in answer to requests from the public. Draft schemes for the partial reimbursement to patients of specialists' and general practitioners' private fees were approved in general, but the Private Patients Plan, sponsored by the B.M.A., is to be consulted before the schemes are finally approved and recommended to the Council.

A meeting of the Private Practice Committee was held on 22 November. Dr. I. M. JONES was in the chair.

The Committee received with regret a report of the death of Dr. R. Hale-White (*B.M.J.*, 11 November, p. 362). He had been a member of the Private Practice Committee from 1959 to 1966, and he had been elected a Fellow of the Association in 1964.

"Mediflash"

Dr. P. R. WILSON, Assistant Secretary, informed the Committee that a letter had been sent to all chief constables about Mediflash, the portable flashing green light for fixing to the roof of a doctor's car when travelling to an emergency (*Supplement*, 11 November, p. 50). So far 19 replies had been received. Ten chief constables sup-

ported the introduction of the lamp; five had been guarded in their support, though they had not said they would ban its use; and four had merely made acknowledgement.

Post-mortem Reports

Dr. G. R. SMITH drew attention to a resolution of the Committee's forensic medicine subcommittee about charges made to general practitioners for post-mortem reports. The subcommittee had considered a complaint from a general practitioner that when he was unable to attend a necropsy on one of his patients and wanted a report on the examination he had to apply in writing and send 6s. 8d. The subcommittee recommended that the Coroners Society should be asked to take steps to "improve the position."

The CHAIRMAN said that coroners had a

right to charge a fee. However, the Coroners Society had given an assurance that this was not usually insisted upon.

Fees for Part-time Services

The CHAIRMAN gave an oral report of a meeting of the Subcommittee on Fees for Part-time Services.

The Treasury was to be asked to increase the mileage fee for part-time work for Government departments. The subcommittee had also decided to make a claim in Whitley Committee C for an increase in the payment for part-time work for local authorities. The subcommittee would be requesting television companies to arrange a fee with a doctor when they invited him to appear on a programme rather than after he had done so.

The Chairman said that fees for services for the National Society for the Prevention of Cruelty to Children had been discussed. The society had suggested that the fees relating to inquests should be taken out of the schedule, since they no longer applied. The subcommittee had considered that the remaining fees should be increased by one-third. The subcommittee had considered that fees for attendance at quarter sessions or assizes should be £7 for each case.

The Chairman said that the subcommittee had received an offer from the Ministry of Health to increase the fees paid for first-aid examinations. The existing fee was £2 per session, plus 5s. per candidate over the first six. The new offer was for a fee of £3 13s. 6d. a session including up to six candidates, with a further fee of 12s. 6d. for each person examined above the first six.

Concluding his report on the work of the subcommittee, the Chairman said that it had considered documents from the Monopolies Commission, and it proposed to inform the Commission that fees payable by patients to their doctors were a matter for agreement between the doctor and the patient. Notes of advice from the Association were in no circumstances binding upon the doctor. It would also be pointed out to the Commission that a doctor's ethical code did not allow him to withhold treatment from a patient because the patient could not pay a fee.

Transmission of Information

The Committee considered the case of a patient who had consulted a general practitioner privately on a matter of urgency. She had not wanted her N.H.S. doctor to deal with this particular ailment. The general practitioner consulted had referred the patient privately to a consultant, who had arranged for her immediate admission to an N.H.S. hospital as an N.H.S. patient. On admission a "hospital attendant" had insisted on recording the name of the patient's N.H.S. doctor and had refused to take a note of the referring private doctor's name, despite the patient's request that the private doctor should be kept informed and her express wish that she did not want her N.H.S. doctor to be informed.

On the patient's discharge from hospital progress reports and discharge notes were sent to her N.H.S. doctor, but at no time did the private doctor who referred the case receive any communication from the hospital.

Dr. P. G. JONES said that because a patient was registered with a doctor as an N.H.S. patient it did not mean that that doctor had a monopoly of that patient. The patient could go to some other doctor for private treatment. A hospital report should be sent to the general practitioner who sent the patient to the hospital. The doctor in the case in question had made "forceful protests to the secretary and chairman of the board of governors of the hospital." He had been told that it was usual when a patient was referred by a doctor other than his National Health Service doctor to send a report to the referring doctor and to the patient's N.H.S. doctor. The correct course, said Dr. Jones, would have been for the general practitioner to protest to the consultant in charge of the case.

Dr. H. FIDLER said that it was usual for a hospital to enter the name of the referring

doctor on the patient's notes. Dr. P. A. T. WOOD said that it appeared great pressure had been put on the patient in this case to give the name of her N.H.S. doctor, though she had expressly asked that he should know nothing about it.

The Committee agreed that any doctor who referred a patient, either privately or through the N.H.S., should receive a report from the consultant, and that no report should be sent to anyone else if it was contrary to the patient's wishes.

Medical Standards for Drivers

The Committee considered a motion from the Newcastle upon Tyne Division which had been among the items on the Annual Representative Meeting's agenda which, owing to lack of time, had not been considered and which had been referred *en bloc* to the Council. The motion stated that the existing method of issuing driving licences to "private drivers" was "grossly inadequate" in that no real effort was made to confirm that the minimum medical standards, as stated on the application form, existed.

Dr. FIDLER wondered whether it should be Association policy that all drivers should be medically examined, and whether the Association should draw up a set of standards for such an examination. Dr. J. T. A. GEORGE noted the words "private drivers." Presumably, he said, that was to make a distinction from public service vehicle drivers. He asked whether the B.M.A. had any policy on medical standards for driving. Drivers

now had only to pass a test to show that they could see a certain distance.

The CHAIRMAN replied that the Occupational Health Committee had drawn up standards for public service vehicle drivers. Other organizations, such as the World Health Organization, were currently considering the matter and it seemed to him better not to duplicate work but to wait for their report.

The Committee resolved to ask the Newcastle upon Tyne Division to "elaborate" its motion, and that at its next meeting the Committee would consider a report of the Occupational Health Committee, issued in 1954, on medical standards in road, rail, and air transport.

Emergency Treatment Service

The CHAIRMAN reported on a meeting of the Central Advisory Committee of the Emergency Treatment Service. He said that the position in London was "fluid." A letter had been sent to every London doctor saying that the B.M.A. service would start in London when there was enough demand for it. There had been no great increase in the number of applicants, said the Chairman, though Telephone Answering Services had several hundred subscribers. Some of the subscribers were clearly acting on behalf of other doctors who were not subscribers, and the switchboard was sometimes flooded with their work. A letter had been sent to subscribers to the Telephone Answering Service reminding them that their subscription covered only their own practices.

Independent Medical Services

The CHAIRMAN, speaking also as Chairman of the Committee of Management of Independent Medical Services Ltd., reported that the Council at its meeting on 25 October (*Supplement*, 4 November, p. 29) had accepted the Private Practice Committee's recommendation "That the Council, recognizing that the policy of extending private practice and of giving all practicable support to Independent Medical Services Ltd. has been approved by the Representative Body, urges resolute and continuous action in this respect by all concerned." The Chairman of Council had asked that the Private Practice Committee should submit a memorandum to the Council setting out specifically the action the Committee wanted the Council to take.

The Chairman said support was needed from the Association to achieve two main objectives: firstly, to acquire for I.M.S. a working capital of £200,000, which had been the original target; secondly, to get more doctors to join the scheme. "The I.M.S. office is flooded every day," said the Chairman, "with applications from patients who wish to use the scheme but who have been unable to find a doctor willing to make the scheme available to them."

The Chairman referred to some of the ways in which the scheme could be advertised more widely. The Representative Body had instructed the Council to introduce an item-of-service insurance scheme for private practice. Draft schemes for paying specialists'

and general practitioners' private fees had been prepared. It would not be impossible to start a hospital scheme without increased capital, the Chairman said, but it would be desirable to have increased capital before launching such a scheme. This applied even more to the scheme for the partial reimbursement of general-practitioner fees. That scheme presented greater difficulties because of the greater risk.

In answer to a question by Dr. SMITH, the CHAIRMAN said that the Central Ethical Committee had ruled that I.M.S. must not provide lists of names of doctors participating in I.M.S. schemes to patients who applied to the office for this information. Dr. SMITH suggested that the Central Ethical Committee should reconsider its decision. If a list of all available doctors were given the patients would have a choice, and, in his opinion, that would not be unethical.

The CHAIRMAN said that at present patients who inquired about doctors operating the I.M.S. scheme were advised by letter to ask their existing doctor whether he would look after them under the scheme. The letter stated that any doctor who wished could participate in the scheme. It then gave the names of doctors in the patient's area who, so far as was known, were operating the scheme. The I.M.S. office would continue to do that, said the Chairman.

Dr. SMITH suggested that honorary secretaries of Branches and Divisions should follow the same policy. Dr. G. CORMACK

pointed out that in some areas the list provided by the I.M.S. office might contain the name of only one doctor. He hoped that the Central Ethical Committee would consider whether its attitude was soundly based in the context of the present circumstances.

The Committee agreed to ask the Central Ethical Committee to receive a deputation to discuss the matter.

Wrong Premise

Dr. WOOD said that it was important to maintain private practice, but in his opinion Independent Medical Services provided a bad scheme, and that was why it was failing. He thought the scheme was misconceived, and that the whole scheme was wrong. The method of payment was wrong. Reimbursement to the patient of part of the doctor's fees was the best method, said Dr. WOOD. A doctor inevitably had many patients under the scheme who needed much attention. Those patients could consume more drugs than the allowance would cover.

In straightforward private practice the heavy-risk patient had to pay a heavier bill and bore the responsibility. The doctor did not have to worry about the number of those patients. Under the I.M.S. scheme the doctor stood to lose. The scheme was failing because it had to compete with straight private practice. He himself had been in private practice for 17 years, and Independent Medical Services and other insurance schemes had been running for varying lengths of time. They had all been based on the idea that private practice was not viable without a scheme. He believed that that premise was wrong. Private practice could survive without any scheme, but too few people realized that.

The CHAIRMAN said that the I.M.S. scheme had been debated twice by the Representative Body. It should be compared with the other schemes in existence. He would not accept that it was a bad scheme, and it was not unattractive to patients. The difficulty was to persuade doctors to operate it.

Dr. P. G. JONES agreed that private practice could survive, but it would be more successful if patients could be offered a scheme. They should have some choice, he said. Dr. J. E. MILLER said that the cost of drugs was often a drawback in private practice. An integral part of the I.M.S. scheme was a scheme for paying the cost of drugs. Dr. WOOD maintained that a reimbursement scheme was the only one that was reasonable. The patient should have to bear some of the ultimate risk. Under the I.M.S. scheme it was the doctor who bore it. If there was the demand from the public for this service that the Chairman had suggested why were doctors not coming forward to join the scheme? The CHAIRMAN replied that doctors appeared to be unwilling to go into private practice.

Dr. CORMACK pointed out that there were many general practitioners who ran well-organized practices from good premises with full ancillary help, and all under the National Health Service. He had been asked by those doctors what could they give their patients privately that they were not giving under the N.H.S., and he had been unable to answer.

Memorandum to Council

The Committee then proceeded to draw up a memorandum for the Council. It was agreed that the following points should be made: private practice should be encouraged; further capital for Independent Medical Services should not be asked for at this stage; efforts should be made to publicize the existing I.M.S. scheme; it should have official backing from the Association, and Division meetings should be held; Division secretaries should be provided with literature, and it was to be hoped they would use the facilities available to them to publicize the scheme.

On a question raised by Dr. MILLER, that the support of the Association for Independent Medical Services had been lukewarm, and on a point that the existence of Independent Medical Services might have created difficulty in the course of negotiations with the Review Body or with the Ministry

of Health, the CHAIRMAN said he "saw no difficulty." The Association had stated that, because of the overall situation in medicine in this country, there was an urgent need to expand the private sector. That had become the policy of the Association. It was useless for it to announce a policy and not to follow it up by all the means in its power.

The Committee agreed to forward a memorandum to the Council based on the discussion which had taken place.

Two New Schemes

The Committee considered proposals for an Independent Medical Services Scheme for specialists. Mr. J. DODD, technical adviser to Independent Medical Services Ltd., attended the meeting by invitation when this item was discussed.

He said that an attempt had been made to incorporate in the specialist scheme the best of the existing insurance schemes and at the same time to produce some original ideas. The proposed scheme was not aimed at the most wealthy sector of the community. It had been thought best to put something on the market for the "emerging middle-class," who would want to insure themselves at a reasonable subscription for the best possible benefits. Therefore there was not a large range of differential subscriptions and benefits; it was a simple, moderate scale, for both subscriptions and benefits. The benefits compared favourably with those of competitors.

After a discussion, in which some aspects of the scheme were commented on, the Committee decided to give general approval to it. It was agreed, however, that before recommending the scheme to the Council the Committee should have consultations with the organizers of the Private Patients Plan—an organization which had been sponsored by the B.M.A.

The Committee also gave general approval to a draft scheme for general-practitioner treatment, in which the benefits would include a partial reimbursement of the doctor's fee and payment for the cost of medicines.

General Medical Council

The General Medical Council met at 44 Hallam Street, London W.1, on 28 November. The President, LORD COHEN OF BIRKENHEAD was in the chair.

Appointment of Members

The appointment of the following as members of the Council was announced: (1) Sir John Richardson, Bt., as representative of the Royal College of Physicians of London, for five years from July 1967. (2) Professor P. J. Randle, as representative of the University of Bristol, for three years from August 1967.

Notice of the reappointment of the following members of the Council was received:

(1) Dr. A. T. Jones, as representative of the University of Wales, for three years from September 1967. (2) Professor R. B. Hunter, as representative of the University of Dundee, for one year from October 1967. (3) Mr. A. B. Clery, as representative of the Royal College of Surgeons in Ireland, for one year from October 1967. (4) Dr. E. T. Freeman, as representative of the Royal College of Physicians of Ireland, for the period of one year from October 1967. (5) Professor A. L. Banks, as representative of the University of Cambridge, for five years from October 1967. (6) Dr. F. J. O'Donnell, as representative of the Apothecaries' Hall of Dublin, for five years from January 1968. (7) Professor W. J. E. Jessop, as representative of the University of Dublin, for three years from November 1967.

President's Address

In the course of his address the PRESIDENT said it was gratifying to record the warm reception given to the new recommendations on basic medical education adopted by the Council at its special meeting in April. It had been widely noted and approved that, unlike earlier recommendations, which were restricted to the undergraduate curriculum, the new recommendations presented in some detail the desiderata of the preregistration period and commented briefly on the subsequent period in which doctors received, or should receive, vocational training for a particular career in medicine.

The Council, the President said, fully concurred with the view expressed in an editorial in the *British Journal of Medical Education*

that "the absence of properly organized postgraduate training (the present control of which bears striking resemblances to the state of undergraduate affairs before 1858) holds up the reform of medical education." It was suggested elsewhere in the same article that "it is in the present absence of vocational training for general practice that the impediment to reform of medical education mainly lies," and that for that and other reasons it was unfortunate that the Council was still inhibited because it had no powers in relation to postgraduate vocational training for the various branches of medicine.

The previous recommendations broke new ground in many respects, said the President, particularly perhaps in the stress which they had laid on the duty (not merely the right) of medical schools "to experiment with different courses and methods of teaching," but they had had less to say about a revision of the examination system than about experimentation in the field of instruction. The new recommendations made suggestions with a view to reducing "the load on the student of a comprehensive examination taken at the conclusion of his undergraduate career." So far as could be judged, licensing bodies were welcoming these suggestions.

There had been no serious criticism of the Council's view that, for the time being, the duration of the undergraduate curriculum should not be reduced. There had been a

wide, probably universal, agreement with the Council's view that the preregistration period stood in need of radical improvement.

Diploma of Public Health

The President referred to a further report of the Council's Special Committee on Public Health on the revision of the rules for diplomas in public health. The diploma in public health was not now regarded only as a diploma which qualified its holder for the tenure of the post of medical officer of health. It was no longer educationally realistic to regard the possession of such a diploma as in itself qualifying a doctor to hold such an appointment. Moreover, the new recommendations envisaged the diploma as fulfilling a wider function by constituting the common academic core of several schemes of training for doctors who might afterwards seek employment in any branch of community health practice. Supplemental vocational training should be arranged and related to the branch of community medicine in which the doctor planned to make his career.

The President said the likelihood that in the not too distant future considerable changes might occur in the structure of the community health services was recognized, and that such changes might affect the vocational training required to equip doctors for this field of practice. The Council was therefore

appointing a standing committee to advise when a further revision of the recommendations should be undertaken.

Pharmacopoeia Committee

The PRESIDENT, in presenting the Report of the Pharmacopoeia Committee, said that certain proposals in the Government's White Paper on forthcoming legislation on the safety, quality, and description of drugs and medicines had been carefully considered by the Pharmacopoeia Commission and by the Pharmacopoeia Committee, and it was suggested that certain further representations might be made to the Ministry of Health. A matter of importance was that the present British Pharmacopoeia Commission demitted when the new *Pharmacopoeia* was published, and the question had arisen whether, in view of the forthcoming medicines legislation, a new Commission should be appointed. The Pharmacopoeia Committee had resolved that a selection committee should be appointed and had nominated the following members of the G.M.C. as members of the selection committee: Professor R. B. Hunter, Professor D. V. Hubble, Professor W. J. E. Jessop, and the President of the General Medical Council; and that the President be appointed as chairman of the selection committee.

(A report of the proceedings of the Disciplinary Committee will be printed next week.)

Branch and Division Meetings to be Held

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

ABERYSTWYTH DIVISION.—At Machynlleth Chest Hospital, Saturday, 9 December, 8 p.m., Dr. A. Jacobs: "Diagnosis and Treatment of Anaemia."

ALDERSHOT AND FARNHAM DIVISION.—At Queen's Hotel, Lynchford Road, Farnborough, Wednesday, 13 December, 8.30 p.m., discussion with representatives of the Regional Hospital Board and the Ministry of Health: "The New District Hospital."

BARNET DIVISION.—At Outpatients' Department, Barnet General Hospital, Tuesday, 12 December, 8 p.m., symposium on "Perinatal Care."

BATH, BRISTOL, AND SOMERSET BRANCH.—At Large Lecture Theatre, Bristol University Medical School, Thursday, 14 December, 8.30 p.m., Sir Norman Skelhorn: "The Medical Profession and the Law." Guests are invited.

BLACKPOOL AND FYLDE DIVISION.—At Savoy Hotel, Blackpool, Wed-

nesday, 13 December, 8.45 p.m., Dr. P. S. Byrne: "Here and There—General Practice at Home and Abroad." Preceded by short meeting to elect representatives to Annual Representative Meeting. (Dinner, 7.30 p.m.)●

EAST KENT DIVISION.—At Kent Postgraduate Medical Centre at Canterbury, Thursday, 14 December, Dr. K. Spittelhouse: "Recent Advances in the Laboratory as they Affect Practitioners."

EAST YORKSHIRE BRANCH.—At Postgraduate Centre, Hull Royal Infirmary, Wednesday, 13 December, 8.30 p.m., presidential address.

GLASGOW DIVISION.—At Marlborough House, Langside Avenue, Tuesday, 12 December, 7.30 for 8 p.m., annual dinner and dance.●

HASTINGS DIVISION.—At Royal East Sussex Hospital, Tuesday, 12 December, 8.15 p.m., Dr. J. A. P. Trafford: "Renal Disease and Dialysis."

HENDON DIVISION.—At Hendon Hall Hotel, Tuesday, 12 December, 8.45 p.m., Dr. J. C. Houston: "Some Unusual Disorders of the Oesophagus."●

KINGSTON-UPON-THAMES DIVISION.—At Kingston Medical Centre, Tuesday, 12 December, 8.30 p.m., Dr. E. H. Rayner: "Methods of Psychological Testing."

LANARKSHIRE DIVISION.—At Alexander Hospital, Tuesday, 12 December, 8 for 8.30 p.m., Professor Ferguson Anderson: "Recent Advances in Geriatrics."

LEEDS DIVISION.—At School of Medicine, General Lecture Theatre, Wednesday, 13 December, 8 p.m., election of representatives.

LONDONDERRY DIVISION.—At City Hotel, Thursday, 14 December, 9 p.m., annual dinner dance.●

MORPETH DIVISION.—At Queen's Head Hotel, Wednesday, 13 December, 7.30 for 8 p.m., jointly with Blythe Division, annual dinner dance.

NORTHAMPTON DIVISION.—At Board Room, General Hospital, Friday, 15 December, 8 for 8.15 p.m., buffer supper; 8.45 p.m., annual general meeting; 9.15 p.m., film: "The Cry of the Bronchi."●

NORTH STAFFS DIVISION.—At Medical Institute, Hartshill, Wednesday, 13 December, 8.15 p.m., Mr. H. Roberts: "Physiology of Menstruation and Pubertal Bleeding."

SOUTH MIDDLESEX DIVISION.—At Ashford Hospital Medical Centre, Thursday, 14 December, 8.30 p.m., annual general meeting.

SOUTH SHIELDS DIVISION.—At Ingham Infirmary, Wednesday, 13 December, 8.30 p.m., Mr. S. J. Rogers: "Economic Change in Agriculture and the Provision of Social Services."

SUNDERLAND DIVISION.—At Medical Society Lecture Room, Sunderland General Hospital, Tuesday, 12 December, 8.15 p.m., symposium by Dr. J. B. Heycock, Dr. J. W. Baird, Dr. P. B. Crone: "Upper Respiratory Infection in Childhood."

SUTTON COLDFIELD, LICHTFIELD, AND TAMWORTH DIVISION.—At Postgraduate Institute, Good Hope Hospital, Thursday, 14 December, 8.30 p.m., Dr. J. Owens: "Some Aspects of Drug Addiction." Guests are invited.

THAMES VALLEY DIVISION.—At Windsor and District Postgraduate Medical Centre, King Edward VII Hospital, Friday, 15 December, 8.30 p.m., meeting to elect representatives to Annual Representative Meeting.

WALSALL DIVISION.—At Three Crowns Inn, Tuesday, 12 December, 7.30 for 7.45 p.m., joint supper meeting with Law Association, Mr. D. D. Lindsay: "Future of Public Schools."●

British Medical Association

Annual Representative Meeting, Eastbourne, 24-28 June 1968

President: ROBERT V. COOKE, M.D., CH.M., F.R.C.S.

Chairman, Local Organizing Committee: I. M. BROWN, M.B., CH.B.

Local General Secretary: C. M. DUNLOP, M.B., CH.B.

Executive Officer: Miss B. E. MIDDLEMISS, B.M.A. House, Tavistock Square, London W.C.1.

Provisional Programme

The Annual Representative Meeting will be held in the Congress Theatre, Eastbourne, from Monday afternoon, 24 June, to Friday, 28 June 1968, inclusive. The Annual Meeting of the Association was last held in Eastbourne in 1931.

The A.R.M. Inquiry Office will be open from 9 a.m. on Monday, 24 June, in the foyer of the Congress Theatre.

There will be a reception to welcome representatives and their ladies in the Winter Garden (adjoining the Congress Theatre) on the Monday evening.

The Representatives' Dinner and Dance will be held in the Winter Garden on the Tuesday evening.

The graduates' dinners will take place on the Thursday evening, and the Service luncheons on the Tuesday and the Wednesday.

The annual breakfast of the Christian Medical Fellowship will be on the Tuesday morning. A meeting of doctors and clergy will be held on the Friday evening.

The Ladies' Club and local information bureau will be in the Grand Hotel, three minutes' walk from the Congress Theatre. It will open on Sunday afternoon, 23 June, and will remain open throughout the Meeting. Many excursions and visits have been arranged for ladies accompanying representatives, and details will be published later.

Pharmaceutical Exhibition

There will be a small pharmaceutical exhibition during the Annual Representative Meeting on the first floor of the Congress Theatre (adjacent to the coffee bar). Further details about the exhibition will be given in due course.

Hotel Accommodation

There is a large choice of hotels with varying tariffs, the majority being situated within walking distance of the Congress Theatre. A selected list is given in the Table, but a full list can be obtained from the Information Bureau, 3 Cornfield Terrace, Eastbourne (Tel. Eastbourne 30183). The local accommodation secretary, Dr. M. J. Mynott, 26 Milnthorpe Road, Eastbourne (Tel. 20945), will be pleased to advise if difficulties arise.

Many of the smaller hotels require a weekly booking from Saturday to Saturday. Since the Meeting coincides with the start of the

holiday season, representatives are recommended to make early reservations by writing direct to the hotel *stating that they are attending the B.M.A. Meeting*. The Association cannot accept responsibility for any of the prices stated in the Table. They are the current tariffs and are subject to alteration without notice.

Selected List of Eastbourne Hotels

Name and Address	Tel. No.	Distance from Congress Theatre	Daily Tariff, Full Board	Number of Bed-rooms		Number of Bath-rooms	
				Double	Single	Total	Private
Burlington Hotel, Grand Parade	22724	½ mile	£3 12s. 6d. to £5 5s.	85	64	87	60
Cavendish Hotel, Grand Parade	27401	½ "	£4 to £8	88	32	105	94
Cumberland Hotel, Grand Parade	30342	½ "	£3 10s. to £4 18s.	44	22	63	43
Hydro Hotel, Mount Road	20643	½ "	£2 11s. to £4 1s.	60	40	62	46
Imperial Hotel, Devonshire Place	20525	½ "	£2 12s. 6d. to £3 10s.	61	69	33	17
Kenilworth and Mostyn, Willmington Square	25387	½ "	£2 9s. 6d. to £4 4s.	50	50	24	3
Lansdowne Hotel, King Edward's Parade	25174	½ "	£3 to £4	56	24	22	9
*Lawns Hotel, King Edward's Parade	25177	½ "	£3 to £4 2s. 6d.	46	14	24	12
Mansion Hotel, Grand Parade	30557	½ "	£2 17s. 6d. to £4 5s.	84	47	68	49
Queens Hotel, Marine Parade	22822	½ "	£3 17s. 6d. to £5 7s. 6d.	95	25	86	66
Sandhurst Hotel, Grand Parade	27868	½ "	£2 14s. to £3 10s.	52	18	34	22
Wish Tower Hotel, King Edward's Parade	22676	½ "	£3 to £4 7s. 6d.	47	33	54	42

Note: All hotels are licensed and have 10% service charge.

* Only Saturday to Saturday booking.

Caravan Accommodation

Representatives who wish to take a caravan to Eastbourne are advised to write to Dr. E. V. Claydon, 30 Eastbourne Road, Willing-

don (Tel. Eastbourne 53250). A block booking has been made at the Castle View Caravan Site, Pevensey Bay, three miles from the Congress Theatre.

Luncheon Arrangements

There is limited lunch accommodation available for Representatives at the restaurant adjacent to the Congress Theatre. It is expected that most representatives will return to their hotels for lunch.

Car Parking and Transport

Daily transport will not be provided from hotels to the Congress Theatre, but it will be provided to and from some of the evening functions.

Travel Facilities

There are air services from Edinburgh and Glasgow to Gatwick, which is 40 miles from Eastbourne.

A motor-rail service from Stirling to Newhaven (13 miles from Eastbourne) operates four nights a week.

Details of these services can be obtained from the M.I.A. Travel Service, B.M.A. House, Tavistock Square, London W.C.1 (Tel. 01-387 8486).

Glyndebourne

It is hoped to obtain a limited number of seats for the Glyndebourne Opera performance on Wednesday, 26 June, and information on how to apply for tickets will be sent to representatives in due course. *In the meantime it is requested that no advance application be made.*

Social Functions and Excursions

Representatives and their ladies will be sent application forms for tickets for social functions and excursions in the spring, when details of prices become available.

Ladies' Club

The Ladies' Club will be in the Sun Lounge on the ground floor of the Grand Hotel (on the sea front, three minutes' walk from the Congress Theatre). A lounge, writing-room, and powder-room will be available together with changing-rooms. There will be a licensed bar and light refreshments. The hotel amenities include a heated, open-air, salt-water swimming-pool.

Ladies' Programme

The Ladies' programme will include all-day tours to Chartwell, Arundel, Rye, Battle, and Penshurst Place; and possibly a visit to Wimbledon for the all-England Lawn Tennis Championships. Among the shorter tours will be visits to Batemans, Burwash; to Hastings, to see the embroidery; to the Brighton Pavilion; to Glynde Place; to the Pestalozzi Children's Village; and to the University of Sussex. It is hoped to arrange a fashion show, a beauty demonstration, and a display of floral art at the Grand Hotel. For the more energetic there will be a walk on the Sussex Downs.

Dinners, Luncheons, and Breakfast

The following graduates' dinners have been arranged for Thursday, 27 June: Aberdeen Dinner, Cavendish Hotel; Bristol Dinner,

Imperial Hotel; Cambridge Dinner, Beachy Head Hotel; Edinburgh Dinner, Norfolk Hotel; Glasgow Dinner, Grand Hotel; Guy's Hospital Dinner, Mansion Hotel; Irish Dinner, Congress Theatre Restaurant; Leeds Dinner, Le Chantecler Restaurant; St. Bartholomew's Hospital Dinner, Royal Eastbourne Golf Club; Welsh Dinner, Cumberland Hotel.

The following Service luncheons have been arranged: Royal Navy, Tuesday, 25 June, Le Chantecler Restaurant; Royal Air Force, Tuesday, 25 June, Mansion Hotel; Royal Army Medical Corps, Wednesday, 26 June, Cavendish Hotel.

The C.M.F. Annual Breakfast on Tuesday, 25 June, will be held at the Grand Hotel.

Further information about these functions, and on where to apply for tickets, will be given later.

Golf Competitions

All golf competitions will take place at the Seaford Golf Club, East Blatchington, Sussex, nine miles from Eastbourne:

Tuesday, 25 June, 9.30 a.m.—Golf Competition for the Nathaniel Bishop Harman Cup (formerly the Treasurer's Cup), divisional winners only.

Wednesday, 26 June, 9.30 a.m.—Ladies' Golf Competition for the Notts Ladies' Challenge Cup (open to women members of the Association and to wives and daughters of members).

Thursday, 27 June, 9.30 a.m.—Golf Competition for the Leinster and Childe Cups (open to all members, maximum handicap 18).

Further particulars available from the Golf Secretary, Dr. D. A. Craib, Westfield, Darley Road, Eastbourne (Tel. 22738).

Provisional Time-table of Meeting

Monday, 24 June

- 9.00 a.m.—A.R.M. Inquiry Office open for registration, Congress Theatre.
- 9.00 a.m.—Local Information Bureau and Ladies' Club open for registration, Grand Hotel.
- 2.00 p.m. to 6.00 p.m.—*Annual Representative Meeting* starts, Congress Theatre.
- 3.00 p.m.—Welcome by the Mayor of Eastbourne, Congress Theatre.
- 8.30 p.m.—Welcome reception, Winter Garden, given by the Eastbourne Division of the Association and the Eastbourne Corporation (Afternoon Dress).

Tuesday, 25 June

- 8.00 a.m.—Annual Breakfast of the Christian Medical Fellowship.
- 9.30 a.m.—*Annual Representative Meeting*, Congress Theatre.
- 12.30 p.m.—R.N. and R.A.F. Luncheons.
- 7.30 p.m.—Representatives' Dinner and Dance, Winter Garden, open also to the local Division (Dinner jacket).

Wednesday, 26 June

- 9.30 a.m. to 1 p.m.—*Annual Representative Meeting*, Congress Theatre.
- 1.00 p.m.—R.A.M.C. Luncheon.
- p.m.—Afternoon programme to be arranged.
- 4.00 p.m.—Glyndebourne Opera (limited number of tickets).
- 7.30 p.m.—Devonshire Park Theatre (play to be announced).

Thursday, 27 June

- 9.30 a.m.—*Annual Representative Meeting*, Congress Theatre.
- 7.30 p.m.—Graduates' Dinners.

Friday, 28 June

- 9.30 a.m.—*Annual Representative Meeting*, Congress Theatre.
- 12.30 p.m. (provisional).—Annual General Meeting, Congress Theatre.
- p.m.—Council Meeting (at conclusion of A.R.M.).
- 8.15 p.m.—Meeting for doctors and clergy, Congress Theatre Restaurant.

General Medical Council: Disciplinary Committee

The Disciplinary Committee of the General Medical Council met at 44 Hallam Street, London W.1, on 29 and 30 November and on 1 and 2 December. The President, LORD COHEN OF BIRKENHEAD, was in the chair.

Indecent Exposure

The Committee dealt first with the case of WILLIAM IRVINE HARDY, registered as of 7 Bedford Street, Belfast, M.B., B.Ch. 1930, which had been adjourned from November 1965 and from July 1967, the charge being that on 17 March 1965 he was convicted of indecent exposure and committed to hospital under section 60 of the Mental Health Act, 1959.

Dr. Hardy was not present but was represented by Mr. N. Leigh Taylor, of Messrs. Hempsons, Solicitors to the Medical Defence Union. The conviction had been admitted on behalf of the practitioner and had been found by the Committee to be proved.

Mr. A. P. P. HONIGMANN, of Waterhouse & Co., Solicitors, presenting the facts to the Committee, said that since 1965 Dr. Hardy had been in hospital and had never been able to be present for a hearing of his case.

After a consideration *in camera*, the PRESIDENT announced that, in view of the circumstances and of psychiatric evidence, the Committee had determined to postpone judgement in the case for a period of two years.

Postponed Judgement

The Committee next dealt with five cases of conviction in which judgement had been postponed.

In the case of PATRICK LAURENCE LYONS, in which judgement had been postponed in November 1965 on account of convictions for being under the influence of drink, the Committee decided, after a consideration *in camera*, to postpone judgement for a further period of one year.

The Committee, in the light of information received, determined that the name of FAROOQUE HAYDER SIDDIQUE should not be erased from the Register, and his case was concluded.

Judgement on Dr. Siddique had been postponed in November 1965 on the charge that he had in May 1964 been convicted (after pleading guilty) of indecent assault.

The case of BARRY ANTHONY ENOCH, on whom judgement had been postponed in November 1966 on a charge that he had been convicted of indecent assault on a male person, was also concluded by the Committee deciding that in view of the satisfactory reports his name should not be erased from the Register.

Name Erased

The Committee decided to erase from the Register the name of CHARLES FREDERICK

ROSS. Judgement had been postponed on Dr. Ross in November 1966 on charges that in April 1964 he had been convicted of being in charge of a motor vehicle when under the influence of drink or drugs, of assaulting a police sergeant, and causing wilful damage to property; that in August 1964 he had been convicted of driving a motor vehicle when under the influence of drink or drugs; and that in March 1966 he had been convicted of being in charge of a motor vehicle when under the influence of drink or drugs.

In announcing the Committee's decision, the PRESIDENT said that if evidence should become available at a later date that Dr. Ross had succeeded in overcoming his addictions to drugs and drink an application for the restoration of his name to the Register would then be sympathetically considered.

Dr. Ross had 28 days within which to appeal.

Further Postponement

The Committee further considered the charge against NOEL PATRICK BURNS, on whom judgement had been postponed in July 1967, that in December 1966 he was convicted of failing to keep a register of dangerous drugs. When judgement had been postponed in July for two years Dr. Burns had been told that he would be expected to make an interim appearance in November.

Mr. HONIGMANN said that the conviction had arisen out of a routine inspection by the police of chemists' registers. Dr. Burns had been purchasing unusually large quantities of morphine and pethidine by presenting prescriptions at chemists marked "Stock Emergency." When the police interviewed him he was unable to account for the way in which the supplies had been used. He had admitted that for the previous 12 months he had been injecting himself with pethidine at the rate of approximately 300 milligrams per day. At the last hearing Dr. Burns had been specifically told that he must "furnish the names of professional colleagues including a consultant psychiatrist."

Dr. BURNS, who was not represented, said that he had not really thought there was any treatment for his particular condition. The doctor advising him had wanted him to have inpatient treatment, but it had not been possible at the time for him to do this.

The PRESIDENT explained that it was not a question of treatment but that the Committee wished to have a report on Dr. Burns's condition.

After a consideration *in camera*, the PRESIDENT announced that the Committee was particularly concerned that Dr. Burns had declined to comply with its specific request, expressed in the clearest possible terms, that he should furnish the name of a consultant psychiatrist in order that the Council might communicate with him as to Dr. Burns's habits and conduct, with special reference to any addiction to drugs. Judgement would stand postponed until May 1969, but Dr. Burns would be expected to appear again in February 1968, and before then to furnish

without fail the name of a consultant psychiatrist who would be able to provide information on his condition, and to supply the names of professional colleagues and other persons of standing to whom the Council could apply for confidential information.

Use of Firearms

The Committee inquired into the charge against QAMAR UZ ZAMAN, M.B., B.S. 1958, U. Punjab (India), that he was on 13 March 1967 convicted (in the name of Abdullah) of (1) wounding with intent to cause grievous bodily harm; (2) carrying a firearm with intent to commit an indictable offence; (3) shooting with intent to murder; (4) carrying a firearm with intent to commit an indictable offence; and that he was ordered to be detained in Broadmoor Hospital and to be subject to a restriction order for a period without limit of time.

Dr. Zaman was not present and was not represented.

The Committee was told by Mr. G. J. K. WIDGERY, Solicitor to the General Medical Council, that Dr. Zaman (otherwise known as Dr. Abdullah) was born in India in 1935, qualified in Pakistan in 1958, and came to Britain in 1961, where he was provisionally registered. He had since then held certain hospital appointments. On 24 October 1966 Dr. Zaman had gone to an establishment in the West End of London at which there were young women acting as hostesses. He sat with one of these hostesses for a while and then decided to leave. He went to the door and then, for no apparent reason, pulled out a gun and fired a single shot. The bullet hit one of the hostesses. The girl subsequently recovered.

Four days later a young girl was walking along Upper Woburn Place towards the Euston Road when she felt a hand against her. Turning round, she found that it was a man. Subsequently it emerged that it was Dr. Zaman. He pulled out a gun and fired twice at the girl. The bullets passed through her abdomen, causing her serious injury, and struck two other pedestrians who were in the street. The doctor was arrested later that day and found to have a gun and a number of unused rounds of ammunition which he had purchased shortly before at some shop in London. He had subsequently been convicted at the Central Criminal Court and ordered to be detained in Broadmoor.

Mr. Widgery added that in June 1965 a complaint had been received by the General Medical Council from one of Dr. Zaman's colleagues at the hospital where he was working at the time that he had been assaulted by Dr. Zaman. The Registrar wrote to Dr. Zaman informing him of the complaint, and that it had been noted in the General Medical Council's records and would be taken into account if at any time Dr. Zaman should apply for full or for temporary registration.

After a consideration *in camera* the PRESIDENT announced that by reason of the convictions proved against him the Committee had directed the Registrar to erase from the

Register the name of Qamar Uz Zaman. Dr. Zaman had 28 days within which to lodge an appeal.

Other Cases for Postponed Judgement

In the case of THOMAS WYN ROBERTS, on whom judgement had been postponed in November 1967 on a charge that he had pleaded guilty in March 1966 to 12 charges of obtaining quantities of Methedrine by false pretences, the Committee decided to postpone judgement for a further period of one year.

In the case of WILLIAM JEREMY WYBRANTS GREENE, on whom judgement had been postponed in November 1965 for two years on a charge relating to the abuse of drugs, the Committee, after considering testimony to his conduct in the meantime, recorded a finding that Dr. Greene was not guilty of infamous conduct in a professional respect in relation to the matters alleged against him in the charge.

That concluded the case.

The Committee postponed judgement for a further year in the case of JEFFREY GREY, on whom judgement had been postponed in November 1966 for one year after he had been found guilty of infamous conduct in a professional respect. The inquiry had arisen out of certain false claims to possessing certain medical qualifications which Dr. Grey had made in applying for medical posts. A letter was received from a consultant psychiatrist at a hospital in which Dr. Grey was a patient.

In the case of HENRY JOSEPH CARON, on whom judgement had been postponed in May 1964, May 1965, May 1966, and May 1967, in respect of a charge that in February 1964 he had been convicted of unlawfully procuring dangerous drugs, the Committee determined to postpone their judgement for a further period of six months.

Infamous Conduct

The Committee gave further consideration to charges against HARI CHAND KHANNA, M.B., B.S. 1956, University of Punjab (India), that on 12 May 1965 he was convicted of stealing 11 books valued at £6 15s.; that in March 1966 he had stolen from another doctor 31 N.H.S. prescription forms; that on five occasions between March and May 1966 he had forged documents purporting to be N.H.S. prescriptions signed by another doctor for the supply of drugs to a patient; that on five occasions between the same dates he had obtained or attempted to obtain from a retail chemist various drugs by means of these forged prescriptions; that in respect of this conduct he had appeared at the Stoke-on-Trent Quarter Sessions in May 1966 and pleaded guilty to three offences, and requested eight others of a similar nature to be taken into consideration; and that in relation to these facts he had been guilty of infamous conduct in a professional respect.

The Committee had postponed judgement on these charges for two years in November 1966.

A further charge now before the Committee was that, while employed as locum-tenent registrar in the accident and emergency department of the Nottingham General Hospital, on certain dates between

April and May 1967 Dr. Khanna had stolen various articles belonging to the hospital, and that on certain dates in that period he had stolen from other medical officers and staff at the hospital various items of personal property; that between April and May 1967 he stole from the Derbyshire Royal Infirmary, where he had on two earlier occasions been employed as a medical officer, various quantities of drugs; that in respect of this conduct he had pleaded guilty on 17 May at the Nottingham Magistrates' Court to three charges of larceny and had asked for 23 other offences to be taken into consideration; and that in relation to the facts alleged he had been guilty of infamous conduct in a professional respect.

It was reported that Dr. Khanna had maintained that these further offences were committed under the influence of drugs, and he had stated that he was having treatment for his addiction at the Mapperley Hospital in accordance with the probation order.

A report from a consultant psychiatrist at the Mapperley Hospital stated: "It was my impression at the time (of his admission) that his behaviour was almost certainly the direct result of excessive use of drugs of the amphetamine and barbiturate groups. He admitted to consuming very large quantities of these substances over a period of four years or so, with consequent deterioration both in his general health, his ability to maintain himself in employment, and a total failure to succeed in obtaining the higher qualification in surgery which was his main aim."

After a consideration *in camera*, the PRESIDENT announced the further charge had been proved to the Committee's satisfaction, and it judged Dr. Khanna to be guilty of infamous conduct in a professional respect in relation to these facts. The Committee's concern, said the President, was the greater because of Dr. Khanna's previous record and because within the last fortnight he had pleaded guilty to further thefts and was waiting sentence on that plea.

The Committee decided to postpone judgement until its meeting in February 1968 on its finding that Dr. Khanna had been guilty of infamous conduct in a professional respect.

False Certification and Covering

SURJIT TANDON, M.B., B.S. 1954, University of Punjab (India), appeared before the Committee on charges that in March 1967 she had signed medical certificates in respect of four persons (two men and two women) certifying that they were suffering from injuries or a medical condition and were unable to attend Court, and that she had not seen or examined the persons and had no direct or personal knowledge of their alleged condition as recorded in the certificates. She was further charged that the certificates had to her knowledge been prepared and written, save for her own signature, by Mr. R. R. Facey, who was employed as a secretary in the practice and was not medically qualified, and that the information on the certificates about the alleged condition of the patients had originally been communicated to or acquired by Mr. Facey and not communicated to or acquired by herself. In these circumstances she had knowingly and improperly lent the weight and authority

of her signature, name, and professional opinion to the statements contained in the certificates, "which required and implied the exercise of professional knowledge, skill, and judgement . . ." and in her professional capacity she had caused or permitted the certificates to be issued when they were to her knowledge misleading in that the matters certified were not founded upon her own knowledge and professional judgement of the patients' condition on the relevant date.

A final charge was that to Dr. Tandon's knowledge Mr. Facey on or about 25 or 26 March had interviewed the patients at the surgery premises and examined them, and that she had authorized or permitted Mr. Facey to write the certificates (or had approved them knowing Mr. Facey had written them) on the basis of information acquired by him of the people named in the certificates; and that thereby she had knowingly and improperly encouraged, permitted, or condoned the exercise by an unqualified and unregistered person of the functions of (1) the examination of patients; (2) the assessment of the clinical condition of such patients; and (3) the formation and expression of a medical opinion as to the condition of such patients; "when such functions required the exercise of medical discretion or skill and ought properly to have been exercised by a registered medical practitioner." In relation to the facts alleged Dr. Tandon was charged with being guilty of infamous conduct in a professional respect.

Outline of Case

The Committee was told that all four of the people named in the certificates had been arrested during the small hours of 25 March for offences in respect of which they were subsequently convicted. Later on the morning of 25 March, a Saturday, they were released on bail. On Monday, 27 March, when they had not surrendered to their bail, all except one of the two women were arrested. The officer arresting them found in the possession of one of the men the four certificates which were the subject matter of the charge. Subsequent to the finding of those certificates, the police had been required to investigate accusations that had been made by some or all of the four people of maltreatment of them by the police during the period before they were bailed. It was in the course of those investigations that the police found out more about the injuries certified on the certificates from Dr. Tandon. The nature of the statements made by Dr. Tandon to the police when interviewed by them, and of her statement in reply to a letter from the General Medical Council, were described to the Committee. The statements in some material respects had differed. Dr. Tandon strongly denied in her statement to the General Medical Council the allegation that she had not seen or examined any or all of the four patients. She had seen them at her surgery on the Sunday morning, 26 March 1967, and she had examined them. She had caused the certificates relating to the injuries of the four patients to be made out on the following morning (27 March), and "it was on that morning that I signed those four certificates." Her statement to the police had been made primarily by way of giving answers to questions asked by them.

She had been able to say that Mr. Facey must have seen the patients on 27 March because she understood that he had taken the certificates to them personally and he had told her that the patients would see her on 28 March. "Mr. Facey was not acting on my instructions when he contacted the Court, and it is obvious to me that he had gone much too far to give advice of a legal nature to the patients. . . . Mr. Facey is a West Indian and two of the patients were also West Indians. It could be that he felt he ought to go as far as he could to assist his countrymen."

In evidence Dr. Tandon told the Committee how she had come to examine the four patients mentioned in the certificates on Sunday, 26 March, and confirmed her explanation of the events as given in her statement to the General Medical Council. She maintained that in her statement to the police she had all the time been referring to the Monday. What she told them was: "I have not seen the patients on Monday," not that she had not seen them at all. They must have misunderstood her in this respect. She did not agree that she came to make out the certificates on the Monday simply because of information conveyed to her by Facey, and without having seen the persons concerned at all.

Difficulties of Understanding

Speaking on Dr. Tandon's behalf, Mr. N. LEIGH TAYLOR, of Messrs. Hempsons,

solicitors to the Medical Defence Union, asked whether the Committee could really accept the evidence against her as sufficient in relation to her denials. He submitted that there was a serious risk of her having been misunderstood, and that it would be dangerous to rely on the statements made to the police. They might not, because of difficulties of understanding, have represented a complete record of what she meant.

After a consideration *in camera*, the Committee decided that the facts alleged against Dr. Tandon in the first four charges had been proved to their satisfaction. In the fifth charge it was found proved that Dr. Tandon had known that Mr. Facey on or about 25 or 26 March had interviewed and examined one or other or all of the four people named in the certificates, and it was also found proved that Dr. Tandon had approved the certificates after they had to her knowledge been prepared and written by Mr. Facey.

Plea in Mitigation

Dr. O. C. FORBES, Dr. Tandon's partner, called by Mr. Taylor on her behalf, said that he had been in practice in Birmingham for approximately ten years. He had found Dr. Tandon perfectly satisfactory. She was a person of the highest integrity. "We practise," said Dr. Forbes, "in very difficult circumstances, and what has been on trial

here is not just Dr. Tandon and my particular practice but the difficulties and shortcomings of general practice in a densely populated, migrant area, where sometimes the law and the rules and correct procedure may have to be bent a little in the interests of keeping people alive." These incidents were completely out of character and he believed Dr. Tandon might have been the victim of a conspiracy. He urged that the doctor should not be condemned at the start of her career as a general practitioner merely because she was working in a difficult area and her knowledge of English was less than perfect.

After again deliberating *in camera*, the PRESIDENT announced that the Committee had judged Dr. Tandon to have been guilty of infamous conduct in a professional respect in relation to the facts which were proved against her. It had, however, taken into consideration the testimony, and the assurances given on her behalf, and had determined to postpone judgement on the question of erasure for a period of one year.

Applications for Restoration

The Committee considered applications from CHARLES BRADY, STANLEY MILLAR, and HARRY SIMMONS for the restoration of their names to the *Register* after disciplinary erasure.

All three applications were successful.

Review Body Evidence

Mr. QUINTIN HOGG, Q.C., has been retained in the place of the late Sir JOHN HOBSON, Q.C., to present to the Review Body the evidence on behalf of hospital medical staff.

General Practitioners in Hospital

The Surrey Branch Council of the B.M.A., at a meeting on 8 November, was unanimous in regarding "the further integration of general practitioners into the hospital services as an urgent necessity." The Branch Council stated that it realized that delays in the provision of general-practitioner beds in general hospitals were inevitable, but it thought it was important to find acceptable ways of introducing general practitioners to inpatient work, as has already been achieved in outpatient work.

Expulsion from Membership

The Central Ethical Committee of the B.M.A. recently considered a suggestion that provision should be made in the articles and by-laws

of the Association for the expulsion from membership of members who contravened recommendations of the British Medical Guild.

The Committee reported to the Council on 29 November the solicitor's advice that this was impossible unless the Association became a trade union. When the British Medical Guild had been formed the point had been made that the Association could not compel its members to comply with Association policy. The solicitor had pointed out that that was an essential aspect of the work of a trade union, and was prohibited to a registered company such as the B.M.A. by clauses in its memorandum of articles inserted at the request of the Board of Trade.

Hospital Building

An amendment of the regulations has now raised the financial limit to which regional hospital boards may plan building and engineering schemes without obtaining ministerial approval from £120,000 to £250,000 (exclusive of the cost of fees and equipment). A circular to regional hospital boards (H.M. (67)82) states that the Minister expects boards to continue to use the hospital building procedures (including the application of current cost allowances) in the planning of all schemes financed wholly or partly from

Exchequer funds, even if the cost is less than £250,000.

The circular also states that these changes do not affect the costs at which building schemes have to be included in capital programmes or capital estimates.

Hospitality

A French doctor's daughter, aged 22, living in Paris would like to stay from 21 December to 3 January with a British medical family who have a daughter of similar age.

A Norwegian doctor's daughter aged 20, living in Naresund, would like to stay *au pair* with a British medical family, living in London from as soon as possible for nine months.

A German doctor living in Füssing would like his 18-year-old daughter to stay with a British medical family as a paying guest from 1 April 1968 for six to nine months.

A French doctor living in Tarbes (Hautes-Pyrénées) would be pleased to receive a British doctor's son aged about 15 to stay with his family for 3 to 4 weeks next Easter. The French doctor has a son aged 15 who is interested in Rugby football and swimming.

A German doctor living in Waiblingen would like his 15-year-old daughter to stay with a British medical family for three weeks from 27 July to 17 August 1968. In exchange the doctor would be pleased to receive

a British girl of similar age from 17 August to 7 September.

Would anyone who is interested please get in touch with Dr. R. A. Pallister, Medical Director, International Medical Advisory Bureau, B.M.A. House, Tavistock Square, London W.C.1.

H.M. Forces

ROYAL NAVY

Surgeon Commander D. G. Bluett has been placed on the Retired List.

Surgeon Lieutenant-Commander H. E. Black has been placed on the Retired List.

ARMY

Colonel H. V. D'A. Iles, late R.A.M.C., has retired on retired pay.

ROYAL ARMY MEDICAL CORPS

Major J. D. G. Malley, from Reserve of Officers, to be Major.

Captain J. Dowson to be Major.

Short Service Commissions—Major W. J. C. Parker, from Active List, to be Major. Captain E. F. Henderson to be Major.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major (Honorary Lieutenant-Colonel) M. M. Medine, M.B.E., having attained the age limit, ceases to belong to the Reserve of Officers, retaining the honorary rank of Lieutenant-Colonel.

Major E. J. Ewell, O.B.E., T.D., has resigned his commission, and has been restored to the rank of Colonel.

Major J. F. Wilson, having attained the age limit, ceases to belong to the Reserve of Officers.

Major J. P. Blandy, from T.A., to be Major. Captain (Acting Major) D. M. Hay, from T. & A.V.R., to be Captain, relinquishing the acting rank of Major.

Short Service Commission—Major T. W. Cross, from Active List, to be Major.

TERRITORIAL AND ARMY VOLUNTEER RESERVE

ROYAL ARMY MEDICAL CORPS

Colonel H. B. Lee, T.D., has been appointed Honorary Colonel, 257 (Eastern) General Hospital (V.) and 221 (Surrey) Field Dressing Station (V.), T. & A.V.R., in a new appointment.

Colonel N. C. Oswald, T.D., has been appointed Honorary Colonel, 217 (Eastern) General Hospital (V.) and 220 (1st Home Counties) Field Dressing Station (V.), T. & A.V.R., in a new appointment. (Substituted for the notification in a *Supplement* to the *London Gazette* dated 4 April 1967.)

Lieutenant-Colonel K. W. N. Palmer, E.R.D., T.D., has been appointed Honorary Colonel, 380 Blood Supply Unit, R.A.M.C. (Volunteers) T. & A.V.R., in a new appointment.

Lieutenant-Colonel H. J. Hambury has been appointed Honorary Colonel, 382 Field Medical Company, R.A.M.C. (Volunteers), T. & A.V.R., in a new appointment.

Major W. A. L. Thompson has been granted the acting rank of Lieutenant-Colonel.

Captain M. Bloch to be Major.

Captain W. V. James has been granted the acting rank of Major.

ROYAL AIR FORCE

Wing Commanders J. G. M. Harrison and M. C. Batchelor have retired.

Squadron Leader E. Anderson has been transferred to the Reserve.

Flight Lieutenant J. A. Baird to be Squadron Leader.

B.M.A. Nuffield Library

The Library service is available to all members of the Association resident in Great Britain and Northern Ireland (and by special arrangement to members of the Irish Medical Association). A copy of the library rules will be forwarded on application to the Librarian at B.M.A. House.

The following books have been added to the Library:

Kirk, R. M.: *A Manual of Abdominal Operations*. 1967.

Kraus, F. T.: *Gynecologic Pathology*. 1967.

London, P. S.: *Nursing Emergencies*. 1967.

Macintosh, Sir R., and Mushin, W. W.: *Local Analgesia: Brachial Plexus*, 4th edition. 1967.

Mackichan, N. D.: *Assisting the General Practitioner*. 1967.

Mawson, S. R.: *Diseases of the Ear*, 2nd edition. 1967.

Milner, E.: *Human Neural and Behavioral Development*. 1967.

Murphy, W. T.: *Radiation Therapy*, 2nd edition. 1967.

Novak's *Gynecologic and Obstetric Pathology*, 6th edition. By E. R. Novak and J. D. Woodruff. 1967.

O'Donnell, J. A., and Ball, J. C.: *Narcotic Addiction*. 1966.

Pollock, J. H.: *A Survey of Surgical Shock*. 1966.

Robbins, S. L.: *Pathology*, 3rd edition. 1967.

Silver, H. K., Kempe, C. H., and Bruyn, H. B.: *Handbook of Pediatrics*, 7th edition. 1967.

Simpson, J. F., et al.: *A Synopsis of Otolaryngology*, 2nd edition. 1967.

Branch and Division Meetings to be Held

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

BIRMINGHAM DIVISION.—36 Harborne Road, Edgbaston, Tuesday, 19 December, 8 p.m., annual Christmas reception and party.●

BRADFORD DIVISION.—At Outpatient Department, Bradford Royal Infirmary, Tuesday, 19 December. 8.15 p.m., jointly with Bradford Medical-Chirurgical Society. clinical meeting, followed by discussion in Medical Societies' Room.

ROTHERHAM DIVISION.—At Gas Showrooms, Friday, 22 December, 8.30 p.m., champagne party.

Branch and Division Officers Elected

HARROW AND HILLINGDON DIVISION.—Chairman, Dr. D. V. Morgan-Jones. Chairman-elect and Vice-chairman, Dr. J. B. Clark. Honorary Secretary and Treasurer, Dr. P. Knight. Assistant Honorary Secretary, Dr. O. W. Samuel.

ISLE OF MAN BRANCH.—President, Professor T. Ferguson. Honorary Secretary, Dr. L. C. Cowley. Assistant Honorary Secretary and Honorary Treasurer, Dr. J. R. McDonald.

LIVERPOOL DIVISION.—Chairman, Professor F. E. Stock. Vice-chairman, Dr. R. Burns. Honorary Secretary and Treasurer, Dr. W. D. Gray.

MANCHESTER DIVISION.—Chairman, Dr. S. Freeman. Senior Vice-chairman, Dr. A. A. Brown. Junior Vice-chairman, Dr. D. L. Cooke. Honorary Secretary and Treasurer, Dr. T. D. Culbert.

MEDWAY AND GRAVESEND DIVISION.—Chairman, Dr. H. R. Gray. Chairman-elect, Dr. I. G. D. Bell. Vice-chairman, Dr. A. E. Wood. Honorary Secretary, Dr. L. F. McWilliams. Assistant Honorary Secretary, Mr. W. H. C. Hamilton. Honorary Treasurer, Mr. E. J. Greenwood.

MID-HERTS DIVISION.—Chairman, Dr. E. W. Thurston. Chairman-elect and Vice-chairman, Dr. D. C. Beatty. Honorary Secretary, Dr. A. J. B. Luke. Honorary Treasurer, Dr. H. Palmer.

NORTH MIDDLESEX DIVISION.—Chairman, Dr. W. J. G. Meldrum. Chairman-elect, Mr. T. M. Hennebery. Honorary Secretary and Treasurer, Dr. A. M. Freeman.

ROTHERHAM DIVISION.—Chairman, Dr. F. W. M. H. Daly. Chairman-elect, Dr. Mary Hargan. Vice-chairman, Mr. P. D. Livingstone. Honorary Secretary, Dr. R. J. Donaldson. Honorary Treasurer, Dr. R. T. Cooke.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—President, Dr. J. L. Ryce. President-elect, Dr. Amy Jagger. Honorary Secretary, Dr. S. Gang. Assistant Honorary Secretary, Dr. W. R. King. Honorary Treasurer, Dr. S. Davies.

SOUTH-WEST WALES DIVISION.—Chairman, Mr. S. Morgan. Chairman-elect and Vice-chairman, Mr. R. L. Rees. Honorary Secretary and Treasurer, Dr. J. S. Lewis.

SUFFOLK BRANCH.—President, Dr. J. C. H. Maidment. Vice-presidents, Dr. A. Sherlock, Dr. J. Davis. Honorary Secretary, Dr. R. A. Leader.

THAMES VALLEY DIVISION.—Chairman, Dr. M. G. Webber. Vice-chairman, Dr. P. H. A. Willcox. Honorary Secretary and Treasurer, Dr. D. Paton. Assistant Honorary Secretary, Dr. M. Charrett.

WARRINGTON DIVISION.—Chairman Dr. D. G. Miller. Chairman-elect and Vice-chairman, Mr. W. Wilson. Honorary Secretary and Treasurer, Dr. P. Barber.

WORCHESTERSHIRE AND HEREFORDSHIRE BRANCH.—President, Dr. G. J. Meikle. President-elect, Dr. M. B. McGinn. Honorary Secretary, Dr. A. A. Vickers.

General Medical Services Committee (Scotland)	86	Association Notices	88

General Medical Services Committee

The G.M.S. Committee had some anxiety about the Minister of Health's intentions on hospital private beds. The relevant clauses on the matter in the Health Services and Public Health Bill now before Parliament were the result of a "package deal" agreement between the Minister and the Joint Consultants Committee. A letter from the Minister explained that his purpose was to make the use of beds more flexible, partly so that private patients needing specialist treatment could be accommodated near the facilities they required. The Secretary of the B.M.A. is to ask for clarification of certain points in the clause, and also of clauses to do with the Minister's powers to manufacture "goods." The General Practice Finance Corporation has increased the rate of interest on its loans to 7½%. The Committee agreed that the proposals of a subcommittee of the Welsh Committee of the Association for an experimental scheme for area health boards in Wales should be published and sent to every general practitioner. The Committee's main fear about area health boards was that under them general practitioners would have less influence than they have now. Some speakers thought they would have more.

A meeting of the General Medical Services Committee was held on 7 December, with Dr. J. C. CAMERON in the chair.

and the Committee agreed, that the Chairman of Council and himself should be allowed to take what action was appropriate.

Minister's Remarks

Dr. G. CORMACK referred to some remarks made by the Minister of Health in the course of his Maurice Bloch Lecture at Glasgow University (*B.M.J.*, 16 December, p. 675). He had said that many doctors, perhaps a majority, particularly among the younger doctors, derived great satisfaction from practising their profession in an environment where they could, without hesitating to consider their patient's means, prescribe and carry out whatever treatment they considered was needed. He had continued: "They may well recognize that the Minister's objectives are the same as their own—namely, to provide the best possible service the nation can afford and as quickly as a vast modernization programme permits. But one looks almost in vain to see this attitude reflected in the official voice of the profession or in the public utterances of those who speak for the profession in a representative capacity."

That last remark, said Dr. Cormack, clearly referred to the B.M.A. and its negotiators, and it was tendentious, provocative, and unjustified. The Committee should make the strongest possible representation to the Minister that he should withdraw it.

Other speakers expressed surprise at the nature of the Minister's statement, and suggested that his arguments should be countered.

Dr. W. W. FULTON, who had been present at the lecture, explained that it was one of a series concerning medicine and the community. Most of it had been a historical review and about partnership in medical care, dealing mostly with the administrative side of medicine. Dr. Fulton advised the Committee to do nothing about the remarks, except to maintain vigilance. Dr. I. M. JONES suggested that if a protest was to be made it should be made swiftly, and the Committee should give its chairman power to act. The G.M.S. Committee should point out that its objective was to give the best possible health service to the nation, but that that was not being achieved because of the method of financing the N.H.S.

Dr. D. P. STEVENSON, Secretary, said that if there had been any statement which sought to discredit the profession's representatives it affected others as well as the G.M.S. Committee. He suggested,

Health Services and Public Health Bill

The Committee discussed the Health Services and Public Health Bill (*B.M.J.*, 2 December, p. 562).

Dr. I. M. JONES referred to clauses in the Bill which would enable the Minister to make accommodation in N.H.S. hospitals available for private patients, without the accommodation having to be specially set aside for the purpose. These facilities would be available for "resident patients" who undertook to pay such charges as the Minister might determine. The Minister could determine different charges for different accommodation and for different services and in relation to different circumstances. The provision of private accommodation would not be allowed to prejudice the services available to those who were not private patients.

Dr. Jones said that the Minister was taking powers to change the whole pattern of private bed accommodation in National Health Service hospitals. The effect of the present proposals would be to remove any designated private beds, save possibly in certain specific hospitals. A Minister, said Dr. Jones, did not usually go to the trouble of putting into a Bill powers which he did not intend to use, and this Bill would give him the power to demand that all private patients who wished to occupy private beds in hospitals should go on a hospital waiting list, and even then they would not be guaranteed the type of accommodation which they sought. They might be put into an ordinary ward and charged fees.

This was not only a breach of an undertaking which had been given by Mr. Aneurin Bevan at the start of the Health Service but it ignored the increase in demand for private beds, as shown by the rising membership of various provident schemes. It ignored the expressed desire of the community. Dr. Jones said that the only purpose behind the Minister's proposals was to take a further step on the road to establishing a monopolistic, monolithic machine for organizing medical care which would make it even more difficult for people who wanted to exercise their choice to do so. The Council had agreed to protest on behalf of the Association to the Ministry of Health (*Supplement*, 9 December, p. 71).

Package Deal

Dr. STEVENSON explained that the Council had instructed him to send a letter to the Minister asking to see him on this matter. Dr. Stevenson pointed out that 18 months ago the Minister had asked the Joint Consultants Committee to discuss his proposals for making changes in the provision of private beds in hospitals. He had presented the Committee with a package deal, in which there were at least three important items. Firstly, the Minister intended to carry out a survey of the private bed accommodation throughout the country, and to study it in the light of the comparative bed-occupancy rates in the public and the private sector. When the figures were published they had shown a marked discrepancy between the occupancy rates in the two sectors. In Dr. Stevenson's opinion the figures were distorted because private patients tended to choose when to occupy a bed, and therefore it was not so easy to keep private beds occupied as it was to keep public beds occupied.

The second item in the package deal had been the abolition of the schedule of fees for patients in private beds—a matter of contention for many years. Consultants could now charge what fees they thought appropriate. The third item in the deal had been that, to make more flexible use of pay-beds, it should be possible for patients in private beds to be transferred to public beds. The intention had been to change the existing situation where it was often difficult for patients needing intensive care, or some special facility, to be cared for in a private bed, and there was nothing in the Act which enabled such a patient to be transferred. The Minister had always been permitted to put public patients into private beds, but it was not permissible to transfer a private patient into a public bed because of his medical condition.

The Joint Consultants Committee and the Central Consultants and Specialists Committee, as it was then, had been a party to this package deal (*Supplement*, 21 January, p. 23), and there had been long discussions with the Government on all aspects of it—including the one under discussion, which had been put in largely at the request of the hospital doctors. They had thought that in the long run a flexible use of beds would be to their advantage.

Dr. Stevenson said that there were a number of points which required clarification, and he had written to the Minister asking him to receive a deputation in advance of the general deputation on all aspects of the Bill.

Flexible

Dr. D. L. WILLIAMS said that he favoured private practice, but to defend it on the ground that it gave priority of medical treatment would be a grave mistake. Private practice should be defended because of the relationship between doctor and patient, because of the personal attention of the doctor. He saw no reason for undue worry about the Bill. Though it gave various powers to the present Minister, it was a flexible Bill and it could be used in a different way by a different Minister.

In reply to Dr. A. J. ROWE, who asked whether the Bill was meant to be permissive

or mandatory, Dr. STEVENSON read part of a letter from the Minister in which he explained the intention of the Bill. The existing N.H.S. Acts required beds to be set aside in special accommodation, and particular beds in particular rooms were so designated. "I would prefer," the Minister wrote, "in the interests of flexibility to be able to approve simply the total number of beds in the hospital which at any one time can be used by private patients. Patients requiring specialist treatment could then be accommodated, where this is desirable, near the facilities they needed, in whatever part of the hospital this might be. No doubt hospitals will generally continue to accommodate most of their paying patients in the same way as at present, but the greater flexibility should make it easier to ensure that the fullest possible use is made of all beds."

Dr. CORMACK said that consultants in the Newcastle upon Tyne area were not satisfied with the proposed arrangement. The agreement had been made by the Joint Consultants Committee, which was "not wholly representative." In the teaching hospital in Newcastle the number of pay-beds had been halved. In some hospitals private beds were scattered throughout the hospital for specialist treatment, and there were good grounds for that. A clearly understood procedure for costing pay-beds for each hospital was being abandoned in favour of a national average costing. The Minister could put on any figure he liked. The combination of that dangerous power, linked with the large reduction in the number of pay-beds, could sound the death knell of consultant private practice.

Dr. H. S. HOWIE WOOD was concerned for the future of small cottage hospitals. He knew of one in which there had been eight private beds before the National Health Service. There were now four, and under the new arrangement there would be two. Dr. Stevenson had suggested that pay-beds were a matter which affected consultants rather than general practitioners, but pay-beds in cottage hospitals were an incentive to good general practice. The G.M.S. Committee should do what it could to make sure that they were preserved.

Supply Goods

The CHAIRMAN said that clause 23 of the Bill, which concerned the power of executive councils to supply goods and materials to persons providing certain services, was to regularize the position. Some doubt had been cast on the legality of the Minister's action in arranging for sterile syringes, for example, to be distributed by executive councils. The clause would enable executive councils to supply, with the Minister's consent, to general practitioners, pharmacists, dentists, and opticians any such goods or materials as it seemed to the Minister they needed for providing a service.

Dr. CORMACK said that the clause should be read with clause 30, which stated that the Minister might sell or otherwise dispose of goods "the production or manufacture whereof by him is involved in the provision of hospital and specialist services; and he may produce or manufacture such goods to an extent greater than that necessitated by the provision of such services in order that

they may be supplied to persons other than those to whom they are supplied by way of the provision of such services." That seemed to give the Minister power to manufacture drugs and to distribute them through executive councils, and to require doctors to use them.

Dr. ROWE said that he did not read into it the suggestion that the Minister could manufacture drugs, because elsewhere in the Bill the words drugs and medicines were specifically used where that was intended. However, the CHAIRMAN pointed out that he had been advised that the term "goods" could mean anything.

Dr. STEVENSON said this could be "a serious move on the part of the Government." He said that clause 30 gave the Minister the power to manufacture in excess of hospital requirements. If paragraph 23 referred only to sterile syringes why should it refer to goods and materials being made available to the pharmaceutical services. If the Government went in for the manufacture of pharmaceuticals that could have a serious effect on the drug industry, and that would jeopardize the general practitioners' freedom to prescribe the drug of their choice.

The Committee decided to ask the Minister for clarification of the meaning of these clauses.

Defence Trusts

Dr. J. E. MILLER, Deputy Treasurer of the Defence Trusts, reported that the appeal to local medical committees was going well. However, some had not contributed to the Trusts since 1953. They were Bolton, Cardigan, Durham, Hastings, East Suffolk, Warley, West Bromwich, and West Hartlepool. Orkney, Stirling, and Clackmannan had not contributed since 1955. South Shields had not contributed since 1956; Blackpool, Great Yarmouth, and Wallasey since 1957; Halifax since 1959; Bristol, Lincoln City, and Shetland since 1960; Burnley, Gateshead, and Hull since 1961; Caernarvon since 1962; Dewsbury, Huntingdon and Peterborough, and Liverpool since 1964; and Birmingham, Bury, Carlisle, Dudley, and Lothian and Peebles since 1965. The following had made no contribution in the last year: Aberdeen City, Aberdeen and Kincardine, Banff, Moray and Nairn, Bedford and Luton, Caithness, Denbigh and Flint, Glamorgan, Huddersfield, Middlesbrough, Northumberland, Renfrewshire, Roxburgh, Berwick and Selkirk, and Southampton.

Dr. Miller agreed that some local medical committees thought that, since they had reached their original target by a certain date, they should not pay any more. However, they had been asked for further contributions since that time.

General Practice Finance Corporation

The Committee received a letter from the General Manager of the General Practice Finance Corporation stating that, "with regret," the Corporation's lending rate for fresh loans had been raised to 7½%. The decision had been made only after the bank rate had been raised three times and

because long-term borrowing rates had risen substantially. The increase would be applied forthwith to all fresh loans.

Dr. S. WAND, a member of the Finance Corporation, said that it was much more

concerned with the long-term than the short-term rate. The Corporation had been at pains to keep the rate at 7½% for as long as possible. Every effort would be made to keep the rate as low as possible.

Publicity for General Practice

The Committee considered a memorandum by Dr. W. Hedgcock, Secretary of the Committee, entitled "Favourable Publicity for General Practice." It suggested that certain proposals should be approved for implementation.

The memorandum stated that the majority of editors of medical school magazines would welcome articles about general practice, on vocational training for general practice, and on the organization of general practice. The articles would be distributed as effectively as possible.

The Claire Wand Trustees had recently agreed to award £500 in 1968 for a Claire Wand Fellowship in General Practice. It was to enable a young, recently fully registered doctor of high attainment to undertake a full course of vocational training. Arrangements had been made to advertise the fellowship and to make the appointment. The B.M.A.'s careers department would shortly be advertising regularly in the medical press its offer to give advice on vocational training for general practice and to assist young doctors to find suitable appointments in general practice. It was also suggested that there should be a register of "general practitioners in training." This could be a useful way of making young doctors feel in contact with the B.M.A. through the G.M.S. Committee early in their career.

The memorandum concluded that the biggest deterrent to general-practice recruitment lay in the medical profession itself. It was proposed to submit at intervals appropriate letters from the chairman of the G.M.S. Committee to the medical press and to national newspapers, and to seek further publicity. Their main theme would be to invite all doctors, especially general practitioners, to play their part in encouraging and helping young doctors to train for a career in general practice.

Dr. E. TOWNSEND hoped that these suggestions would be just a first step. Students, when they qualified, tended to be conditioned to hospitals. There was a tendency in universities and medical schools to denigrate general practice, so it should be the G.M.S. Committee's aim to get at the medical student before qualification. Local medical committees and local Divisions of the B.M.A. could help in this.

Career Structure

Dr. B. L. ALEXANDER said that the dean of postgraduate studies in Manchester offered hospital junior staff a plan for a career, and they were given advice on the openings in all the specialties, including general practice. Dr. T. K. COOKE believed that the position would never be altered until a career structure could be offered in general practice. The G.M.S. Committee had always opposed suggestions for a career structure. It had resisted paying a man according to his merits. It had always

come down in favour of not paying one doctor more than another. Such a system would not attract doctors into general practice.

Dr. MILLER spoke of the "jaundiced view" of general practice taken by consultants and hospital staffs, either obliquely or intentionally. All the good work done by articles in students' journals and talking to young men was undone by one single unfavourable action on the part of a consultant who had never been in general practice. A department of general practice should be established in every university town, with the approval of not only the university authorities but also of consultants. At the moment general practice was often joined with social medicine and given a minor part in an already small department. The G.M.S. Committee should take a strong stand now.

Dr. JOAN K. SUTHERLAND disagreed that young men should be tackled in their first year of hospital work. They should not be asked to commit themselves then, but the option should remain open. General practitioners should teach not only in the general practice department but also in the wards. Appointments to the department should lay emphasis on general practice as well as on social medicine.

Dr. C. J. WELLS believed that the education of the future doctor started on the other side of the consulting-room desk, and general practitioners should set an example of what they were trying to do. He feared terms like "social medicine" departments and "community medicine." Dr. A. ELLIOTT reminded the Committee that the report of the Royal Commission on Medical Education would shortly be published. Then the Committee should make its stand. It should say to the Minister, "We expect you to build into the educational system the major specialty of general practice, and we expect you to do it now."

Dr. RIDGE said every family doctor should examine his method of practice and his practice organization. The most powerful incentives were the example set by established general practitioners.

The Committee agreed that the proposals in Dr. Hedgcock's memorandum should be implemented.

Area Health Boards

Dr. G. MURRAY JONES introduced the second report of the Welsh Committee's sub-committee on area health boards. The Council (*Supplement*, 9 December, p. 65) had asked that "the standing committees be asked to forward their further views on the area health boards report to the Welsh Committee not later than three weeks before the date of the January Council meeting." The Council had also decided to set up a working party "to bring the Porritt Report up to date, to study all other relevant reports

on the administrative structure of the National Health Service, and to correlate the views of the standing committees on the subject" before the Minister of Health issued his "Green Paper" on the administrative structure of the N.H.S.

Dr. Jones hoped that the report would receive publicity. Too often the profession had been blamed for destructive criticism of the N.H.S. Here was something which was being offered for its "salvation." He believed that the salvation depended upon decentralization and bringing back a sense of competition. A "Green Paper" was not a policy statement but a paper for information. He hoped that the B.M.A. would keep one step ahead of the Minister of Health.

The Welsh Committee was not saying that area health boards were the solution to all the problems of the National Health Service. It was saying that they should be tried out in Wales. Dr. Murray Jones said the reaction of the local authorities in Wales to the proposals was mixed. Some saw their empires tottering; others thought the proposals sensible.

Local Authority Opinion

Dr. B. D. MORGAN WILLIAMS said that an area health board had been proposed for the Highlands and Islands of Scotland, but he understood that the Inverness Local Medical Committee had thought that the area was too big. It would be difficult for any political party to push this idea through against its own supporters. Local government consisted of supporters of all three parties, and it was likely that the parties would listen to those who took part in local government. It was going to be difficult to convince them that they should lose one of their major functions.

What particularly worried Dr. Williams was the suggested membership of an area health board. It was suggested that there should be included ten representatives of the professions, of whom not less than five would be elected by the medical advisory committee. Even if "not less than five" was seven, how many of those would be general practitioners? The hospital doctors would want one or two, the public health service would want one or two. The general practitioners would be lucky to get more than three out of a total membership of an area health board of 20. That would leave general practice in a less influential position than it was now.

Dr. C. J. SWANSON said that the Birsay Committee (*Supplement*, 8 July, p. 23) had suggested that the best way to administer the medical services of the Highlands and Islands was by an area health board.

Area health boards were a means to an end, the end being the functional integration of the profession. Administrative co-ordination was the first step towards that. It was thought that a population area of about a quarter of a million was right for a board to administer. It would take over all the functions of the Health Service and there would be unity in the profession.

Dr. HOWIE WOOD thought that the experiment of area health boards ought to be tried. An experiment in maximum liaison and co-operation between the three arms of the Service had never been carried out.

Equal Partnership

Dr. D. L. WILLIAMS explained that, according to the Welsh proposals, there would be six or seven area health boards under a Welsh Health Council. It was proposed that there should be equal partnership between the public and the health professions in running the service. Each side of the area health board should be elected and not selected. It was hoped that the local authorities would not be losing power, but in fact in many ways they would be gaining it. At the moment they were completely unrepresented in the administration of the hospitals. The Welsh Health Council would be composed of a Welsh board of health on one side and of the representatives of the area health boards on the other. The idea was that they should settle the problems of the Health Service over the table and be involved in the running of the Service. That was thought to be a way of reconciling central planning with Ministerial responsibility.

Objections have been made about the position of general practitioners. Ideally, Wales would like to eliminate the tripartite administrative system, but it did not think it could go so far as Dr. Swanson would like to in one move. Dr. Williams thought the position of general practitioners would be not only safeguarded but strengthened. Their status as independent contractors would be preserved, and local medical committees would acquire greater powers, because they would act as the subcommittee in general practice of the main medical advisory committee of the area board. General practitioners would be represented on the medical advisory committee of the board. It did not matter how many representatives they would have on the board itself; it was more important to influence the policy decided in the main medical advisory committee of the board, on which general practice would be strongly represented. The interests of general practice lay also in the other branches of the Service.

Dr. Williams said he believed that area health boards would be one of the corner-

stones in the rebuilding of the Health Service. The demand for devolution of control did not spring from Welsh or Scottish nationalism but from a wish to bring control of the Health Service nearer to the people. That was a movement that all could support. The Welsh Committee's report was for discussion.

Dr. SPEAKMAN formally proposed that the report should be published, and sent as soon as possible to every doctor in the country for discussion and debate. He said that the profession must not make the mistake that it made in 1948. This time it must be ahead of the politicians.

Integration

Dr. RIDGE said he wanted to amend Dr. Speakman's motion, so that in addition to sending the report to every doctor the G.M.S. Committee should send out a commentary on it. It was assumed that functional integration would automatically follow administrative integration. In Dr. Ridge's opinion that was a delusion. The working together of individuals from different branches of medicine depended not so much on the administrative set-up as on the people themselves. It was up to the profession to integrate itself. Integration would not follow from integration of the administrative organization.

Dr. Ridge referred to the following statement in the report: "The National Health Service as a whole is necessarily responsible to the public, both in total and in detail, for the public money it spends, and answers at present to Parliament. It is therefore suggested that, while the Minister should continue to be responsible to Parliament for the adequacy of the total sum allotted to the Welsh Health Services, the Welsh Health Council should divide this sum between the area health boards."

The profession, said Dr. Ridge, had just achieved a revolution in that it had got away from a fixed sum in remuneration, yet now

the report was asking to go back to a fixed sum to be divided out. Supposing that there was a sudden increase in population in Wales, or there was an epidemic which called for extra resources, where would the money come from? To go back to a pool system of remuneration would be dangerous.

The second point was one of status. For anyone to suggest that a local medical committee which was a subcommittee of a medical advisory committee, and which influenced the area health board through the medical advisory committee, was in any way comparable to the existing relationship between an active local medical committee and an executive council was to be deluded. General practitioners had secured under executive councils a position of strength, of which there was no parallel anywhere else in the Health Service. General practitioners could occupy key positions in executive councils. Dr. Ridge said that he could see nothing but a reduction in their status under the suggested arrangement.

Dr. D. L. WILLIAMS, in reply, said it was not suggested that local medical committees should be a subcommittee of the medical advisory committee. They would have two functions; firstly, the existing ones, and, secondly, they would act as the subcommittee of the medical advisory committee. It was a dual purpose committee. A lot of what Dr. Ridge had said stemmed from a natural wish not to want to change the *status quo*.

The Committee accepted Dr. Speakman's motion to publish the document and to send it as soon as possible to every general practitioner in the country, for discussion and debate.

It also set up a working party to send out a commentary, as suggested by Dr. Ridge, at a later date, and also to act in accordance with the Council's request to formulate the G.M.S. Committee's views on the administration of the Health Service. The working party was to be asked to prepare a report on the advantages and disadvantages of area health boards, and it was decided that it should consist of members who were for and who were against the scheme.

Organization Committee

A meeting of the Association's Organization Committee was held on 7 December. Dr. J. S. NOBLE was in the chair.

Honorary Secretaries Conferences

The CHAIRMAN presented a report of the Chairman's Subcommittee.

He said that it had considered the future of the conferences of B.M.A. honorary secretaries and it recommended: (1) that an annual United Kingdom conference of honorary secretaries in London was essential, and, in the light of the present need to recruit new members, it was imperative; (2) that the annual conference for newly elected honorary secretaries was also valuable, but, to save money, it should be reduced to one day, immediately preceding the United Kingdom conference; and (3) that, in order to obtain "the optimum value from both conferences," the Organiza-

tion Committee should determine the agenda and arrangements. The Subcommittee believed that conferences of honorary secretaries in regions could also serve a valuable purpose, particularly in future in association with B.M.A. regional councils.

Dr. S. WAND, Treasurer, drew attention to the current financial difficulties of the Association (*Supplement*, 9 December, p. 66), and said that before the Committee agreed that an annual United Kingdom conference of honorary secretaries was essential it should first consider whether there had been any adverse results from not holding the honorary secretaries conference in 1967.

Dr. J. S. ROSS said that a well-organized honorary secretaries' conference was really a "sales drive." It was the time when honorary secretaries should be inspired to recruit new members.

Dr. C. C. LUTTON suggested that there should be a meeting of honorary secretaries

twice a year in every branch area, and an effort made to ensure that at least one representative from each of those meetings attended the central annual conference. He thought that failure to hold an honorary secretaries' conference would have a severe effect on membership in two to three years' time.

Dr. WAND asked whether there was any evidence that the honorary secretaries' conference increased membership, or that the failure to hold a conference last year had been regarded throughout the country as a mistake.

Dr. J. M. DUNLOP supported the continuance of the conference of newly appointed honorary secretaries because it gave them the opportunity to meet B.M.A. staff, which was helpful. Dr. R. P. HENDRY said that he had always thought that the honorary secretaries' conferences were worth attending. The conference was a non-policy-making body, but it was not precluded from dis-

cussing* politics nor from making recommendations to the committees of the Association.

Mutual Need

Dr. A. W. MACARA considered that it was essential to hold the newly appointed honorary secretaries' conference. A newly appointed honorary secretary could not hope, he said, to understand what made the Association tick unless he saw it working at the centre. Dr. Macara did not think any useful economy would result by reducing the length of the conference from two days to one.

Dr. D. BURRELL said that the honorary secretary should feel as needed at Headquarters as Headquarters needed him in the periphery, and without some contact with the central organization keenness in the Division tended to slacken.

The CHAIRMAN suggested that the first recommendation might be taken in two parts. First, he proposed, and the Committee agreed, that an annual U.K. conference of honorary secretaries in London was desirable.

Secondly, he proposed that, in the light of the need to recruit new members, it was imperative to hold a conference in 1968.

Dr. WAND suggested that there was no evidence to show that in the past such conferences had helped recruiting.

The CHAIRMAN reminded Dr. Wand that the Organization Committee had been asked to organize a recruiting drive, and the basis of that drive was that honorary secretaries "should be instructed in an expert manner on recruitment." Of course, said Dr. Noble, there was no evidence to show that a conference had helped recruiting, but he considered that the Council should make the final decision, and that the Organization Committee should base its recommendations on what it believed to be in the best interests of the Association.

Dr. A. N. MATHIAS, Chairman of Representative Body, said that if honorary secretaries were to be recruiting officers then regional conferences would be more valuable than central conferences, because areas where recruitment was particularly needed could be identified.

Dr. R. A. A. R. LAWRENCE moved by way of amendment that the second part of the recommendation should read "and to assist honorary secretaries to deal with proposals relating to organization and recruiting, a conference should be held in 1968."

The amendment, duly seconded, was carried.

The substantive motion was carried by 10 votes to 2 votes.

Dr. DUNLOP moved that the words "also valuable" in recommendation (2) should be deleted and the word "essential" substituted.

The amendment was carried.

The remaining recommendations, as set out, were adopted.

Hastings Wine Club

The CHAIRMAN welcomed Dr. H. G. Dowler, chairman of the Hastings Wine Club, and Dr. L. S. Potter, its secretary, and invited Dr. Dowler to report on the club's activities.

Dr. DOWLER reported that the Hastings Wine Club was a success and its finances were in a healthy state. It gave a service to members which cost the Association nothing. The number of members at present was about 5,500, and the number was increasing. The club's aim was to encourage its members to learn about and to appreciate wines, for which purpose it organized tours of vineyards and arranged wine tastings.

Referring to the trade discount scheme introduced recently by Independent Medical Services Ltd., which included wines and spirits, Dr. Dowler recalled that when he took part in a Council debate on the matter he had expressed the view that it was wrong in principle for a service sponsored by the B.M.A. to set up in direct competition with a service already given by the Association (*Supplement*, 4 November, p. 34). Dr. Dowler also refuted some of the suggestions made in that debate by Dr. I. M. Jones, including the suggestion that the Hastings Wine Club was bound hand and foot to a particular firm.

Dr. J. F. PIGOTT said that the Hastings Wine Club had an educative and social function, and he deprecated the competition from within the Association. There was little reason why Independent Medical Services should compete with the Hastings Wine Club, and he suggested that it should be asked to desist from doing so and to concentrate on its other activities.

Professor D. E. C. MEKE said that the I.M.S. scheme might have set a precedent for all sorts of outside bodies to enter into competition with the Association's activities. He suggested that the Organization Committee should deprecate the action of the Council in facilitating competition from an outside body with the activities of the Association.

The Committee agreed to convey its regret to the Council that the Council had seen fit to sponsor a body other than the Hastings Wine Club "in relation to the supply of wines and spirits to members."

Constitution

The Committee gave further consideration to proposals for the reform of the constitution of the Association, which had been submitted by the East Yorkshire Branch.

Dr. R. L. Luffingham and Dr. W. Ferguson, of the East Yorkshire Branch, attended the meeting and answered a number of questions on specific points raised by members of the Committee. The matter is to be discussed again at the next meeting of the Committee.

Election Addresses

The Committee adopted a recommendation of the Chairman's Subcommittee that the existing procedure governing the support that could be given to candidates in the elections to the Council should be discontinued and replaced by the following procedure: (1) an election address not exceeding 325 words from each candidate could be issued with the voting papers; (2) the names of the sponsors should appear on either the voting paper or the election address; and (3) no other form of

written canvassing, paid for either from private funds or from Association funds, should be permitted.

The Committee also agreed that the procedure adopted for the support and distribution of election addresses in elections to the Council should apply also to elections of representatives of constituencies to the Representative Body and to elections of representatives of constituencies to the Junior Members Forum.

Junior Members Forum

Dr. PIGOTT drew the Committee's attention to a resolution of the Hospital Junior Staffs Group Executive Committee in which it was pointed out that the H.J.S. Group Council was disturbed by the increasing electoral function of the Junior Members Forum.

The Group Council considered that, as the name suggested, the Junior Members Forum was a discussion group where junior members of the B.M.A. in all branches of the profession could meet and exchange ideas. The Group Council did not think the Junior Members Forum should be a policy-making body, and it was concerned that representatives elected by the Forum had at times claimed to speak for hospital junior staff. The Group Council emphasized its belief that any representation of young general practitioners and hospital doctors should come from the Assistants and Young Practitioners Subcommittee and the Hospital Junior Staffs' Group Council respectively.

The CHAIRMAN pointed out that under the revised constitution of the Association the Assistants and Young Practitioners Subcommittee and the Hospital Junior Staffs Group Council were represented on both the Council and the Representative Body. The Junior Members Forum had two representatives on the Representative Body, one of whom must be engaged in other than general practice or the hospital service, and similarly would have two representatives on the Council.

After a short discussion the Organization Committee expressed its sympathy with the views outlined in the resolution, and remitted it to the Chairman's Subcommittee for further consideration, in consultation with the junior-member bodies concerned.

Branches

The Committee adopted recommendations by the Committee on Overseas Affairs that the Borneo Branch of the Association should be dissolved and the possibility of its affiliation with the Sarawak Medical Association be explored, and, similarly, that the Fiji Branch of the Association should be dissolved and the possibility of its affiliation with the Fiji Medical Association be explored.

Membership

The CHAIRMAN reported that the membership figure of the Association was 66,619, compared with 69,747 for the comparable period in 1966. The "home" membership was 49,173, compared with 49,694 for the comparable period in 1966.

General Medical Services Committee (Scotland)

The General Medical Services Committee (Scotland) met on 7 November. Dr. ALISTAIR CLARK was in the chair.

Highlands and Islands

Dr. C. J. SWANSON, chairman of the Highlands and Islands Practitioners' Subcommittee, presented the Subcommittee's comments on the Birsay report (*Supplement*, 8 July, p. 23). He said that, though the Subcommittee endorsed most of the recommendations in the report, it had not supported the recommendation for a Highlands and Islands practice allowance (H.I.P.A.). Instead the Subcommittee preferred the continuance of inducement payments. Much attention had been given to the suggested establishment of a Highlands and Islands Area Health Board.

The Subcommittee had been in favour of that, and had suggested that a small "lay" majority on the board would be advantageous and that the lay members should be appointed by the Secretary of State for Scotland rather than by the local authorities. The Subcommittee had been in no doubt that up-to-date transport and communications were the overriding considerations, and that until these facilities were adequate there could be no resiting of practices.

Dr. S. PEACE said that he and his colleague Dr. D. D. Johnstone were preparing a paper on a salaried service. They had decided that there were two issues which needed clarifying: (1) the definition and function of a general medical practitioner and of his ancillary staff, and (2) the contractual relationship which the doctor in a salaried service would have to accept with the Scottish Home and Health Department. The general practitioners in Orkney were in favour of examining "payment by salary."

Dr. C. S. SANDEMAN did not think it would be feasible to administer the Area Health Board for the Highlands and Islands from either Glasgow or Edinburgh in preference to Inverness.

It was agreed to revise the Subcommittee's comments on the Birsay Report, after which they would be presented to the Scottish Home and Health Department by the Chairman's Subcommittee, together with the Highlands and Islands Practitioners' Subcommittee, on 12 December.

Dispensing Doctors

Dr. SWANSON reported on a meeting held with the Scottish Home and Health Department on 1 November.

There had been an interchange of views, he said, on the principles of dispensing and the differences in practice between Scotland and England. A case had been put forward for a realistic dispensing capitation fee negotiated on the basis of a percentage of what it cost a doctor to "physic" a patient. The fee would vary according to the dispensing statistics of the doctor.

Matters for Further Discussion

The Committee considered a letter from the Dundee Local Medical Committee about reclaiming selective employment tax for part-time employees.

Dr. D. W. K. BUCHANAN said that it should not be necessary to reclaim from two sources. It should suffice to reclaim from the executive council without recourse to the Ministry of Social Security.

It was agreed to take the matter up with the Scottish Home and Health Department.

The General Practice Finance Corporation was criticized again by the Committee for its failure to include loans for equipment. It was decided again to urge on the Scottish Home and Health Department that there should be no need to prove difficulty in borrowing elsewhere, since already the Government possessed reserve powers under the N.H.S. Act, 1966, which could be implemented.

A letter from the Scottish Home and Health Department was before the Committee concerning the scheme for the reimbursement of rent and rates and the "grossing-up" factor to be applied when the practice premises formed part of a doctor's residence. The Committee found it difficult to deal with this matter without fuller financial data, and it was agreed to ask the Department to provide this.

Dr. J. S. GARDINER reported that open access by general practitioners to the radiology department at Falkirk Royal Infirmary had been withdrawn since July without prior consultation with the local doctors. The matter had been taken up with the Western Regional Hospital Board, but to no avail.

The Committee received a circular, which was being issued to executive councils, which described the arrangement for registering adopted children with an N.H.S. doctor.

Dr. JOAN K. SUTHERLAND inquired whether adequate precautions were taken to ensure that the name of the child to be adopted was removed from the medical card before it was forwarded to the executive council.

The Committee received a note on the N.H.S. (Scotland) Hospital Statistics.

Dr. W. M. PATTERSON pointed to the need for publicity about hospital consultations which were not taken up. For instance, the number of outpatients who had not kept appointments at the orthopaedic department of the Edinburgh Royal Infirmary was approximately 30%, he said, and he suggested that a notice might be displayed in doctors' surgeries advising that patients who were unable to attend hospital at the time of their appointments should let the hospital know.

The Committee had been approached by the Scottish Home and Health Department about the appointment of a whole-time locum for general practitioners in Shetland, whose salary would be guaranteed by the Zetland Local Medical Committee.

Dr. PEACE referred to the difficulty in Shetland and in Orkney in procuring locums for holidays and emergencies, and he commended the scheme.

The Committee decided first to get the agreement of the Zetland Local Medical Committee and then to encourage the idea at the Scottish Home and Health Department.

Ambulance Service

The Committee discussed the question of the number of general practitioners who could be nominated to the regional committees of the St. Andrew's Scottish Ambulance Service. Many speakers were not satisfied that two general practitioner members out of a total regional committee membership of 12 was adequate, and it was suggested that four general practitioners would match the number of members nominated by the hospitals—that is, two from the regional hospital board and two from hospital boards of management.

It was agreed that meantime local medical committees should be asked to submit nominations at once to the General Medical Services Committee (Scotland), who would appoint two for each region from such nominations.

Medical Care of Hospital Staff

It was reported that the Scottish Committee for Hospital Medical Services was considering recommending to the Scottish Home and Health Department that the routine medical care and pre-employment examination of hospital staff should be undertaken by general practitioners appointed by hospital boards for this purpose. At present these duties were undertaken in many hospitals by hospital junior medical staff.

Dr. S. J. HADFIELD, Scottish Secretary, explained that the matter would be dealt with in detail in the report of the Joint Committee on the Health of Hospital Staff, under the chairmanship of Sir Ronald Tunbridge.

The Committee agreed to consider the matter again when the report was available.

Single-handed Rural Practitioners

The Committee considered a report that the Rural Practitioners Subcommittee had recently reviewed the existing position of single-handed rural practitioners.

The Subcommittee considered that these doctors were in a disadvantageous position in many ways, but chiefly because of their inability to qualify for the group practice allowance of £200 per doctor. Information had been collected from local medical committees interested in this matter, and it was hoped to make progress with the Home and Health Department on a suggestion that the words "common main surgery" should be removed from the regulations, thus facilitating the formation of groups.

The Committee adopted a resolution of the Subcommittee, which stated that it was not in favour of closing the rural practitioners' fund and incorporating mileage payments in the basic practice allowance, but that it

would accept a proposal to negotiate for "new money" from which mileage payments for maternity medical services should be made.

Reports

The report of a joint medical planning committee on health centres and other "joint-user" premises in Renfrewshire was received.

The Committee decided to remit the report to its Planning Subcommittee for consideration.

Dr. JOAN K. SUTHERLAND pointed out that the Scottish General Dental Services Committee had expressed disquiet about the general development of health centres and had recommended that close co-operation on the matter between the G.M.S. Committee (Scotland) and the Scottish General Dental Services Committee should be maintained.

Another report received by the Committee was the eighteenth report of the Scottish Medical Practices Committee.

The Committee discussed the problem of designated areas, and Dr. W. K. DAVIDSON thought it was time to determine the criteria to be used for classifying an area as "designated." In this connexion it was decided to ask the Planning Subcommittee to consider certain paragraphs of the report.

Dr. SWANSON said that in 1966 only 17 partnership agreements had been granted certificates under Section 36(9) of the N.H.S. Act, 1947, out of a total number of 129 partnerships formed. He stressed the importance of submitting agreements for proposed partnerships to the Scottish Medical Practices Committee.

A memorandum by Dr. C. DALE FALCONER, Assistant Scottish Secretary, entitled "Disaffection Towards General Practice," was received.

The CHAIRMAN said that the document aimed to set out the underlying causes of the current discontent with general practice in the profession which had resulted in fewer doctors entering this branch of medicine.

The Committee decided to consider the document at its next meeting.

Repeat Prescriptions

Ayrshire Local Medical Committee submitted for the Committee's consideration a special card in current use for repeat prescriptions.

The Committee resolved that it was not in favour of the introduction of a card for repeat prescriptions as a general rule, though it was appreciated that general practitioners were at liberty to use these in their practices if they wished to do so.

Scottish Committee for Hospital Medical Services

The Scottish Committee for Hospital Medical Services met in Edinburgh on 4 December. Mr. N. G. C. HENDRY was in the chair.

The CHAIRMAN welcomed Drs. W. Norris, B. Groden, G. M. McAndrew, and K. Sinclair as new members of the Committee.

The Committee agreed with the suggestion of Dr. J. G. M. HAMILTON, Chairman of its Finance Subcommittee, that the title of the Central Consultants and Specialists Committee (Scotland) Fund should be changed to accord with the new title of the Committee. In future the Fund would be known as the Scottish Hospital Medical Services Committee Fund.

Remuneration

A paper was received from the Scottish Home and Health Department setting out suggestions for the pay of general practitioners and others who, though not consultants, were undertaking unsupervised specialist work in certain remote areas. It was reported that the General Medical Services Committee (Scotland) would be examining this document and that there would be a joint meeting with the Home and Health Department to discuss the arrangements.

The CHAIRMAN pointed to the need for some sort of scrutiny of those doctors who were undertaking this work to ensure that their competence and qualifications were suitable. Dr. H. M. URQUHART said that the Committee should not agree to any scrutiny that excluded the thoroughly competent doctor who nevertheless had no higher qualification.

Mr. R. J. A. FRASER considered that the suggestions for special remuneration should be supported, and that the document before the Committee should be used as a basis for discussion.

Hospital Posts

Professor A. FORRESTER submitted a memorandum from the Committee's Anaesthetic Services Subcommittee about senior registrars in the specialty of anaesthetics in Scotland. The memorandum provided figures which showed that in the past two years experience had confirmed the subcommittee's conclusion that the establishment for senior registrars in this specialty was insufficient to provide an adequate number of fully trained and qualified consultants for the expected consultant vacancies. It was submitted that the minimum number of senior registrar posts for the next year should be 24, which was two more than the revised establishment as it now stood.

The Committee agreed to pass the memorandum to the Joint Consultants Committee (Scotland) with a request that it should be submitted to the Scottish Home and Health Department.

The CHAIRMAN remarked that it was encouraging that note was being taken of such documents by the Scottish Home and Health Department.

The Committee was pleased to note that there had been an improvement in the amount of consultation with local doctors before consideration of the establishment of a new medical assistant post. It was reported from each region that the deficiencies in such consultations were being eliminated, and that the Advisory Committee on Consultant Establishments was now being informed of the views of regional committees as well as all other relevant information, when it was considering a request for the establishment of a new post.

The Committee discussed the machinery for the consideration of the report of the Joint Working Party on the Organization of Medical Work in Scotland. Arrangements had already been made for regional discussions. It was decided to obtain copies for hospital junior staff group committees, and

to provide at least one copy in each hospital for the junior staff. Arrangements were made to collate the views of regional committees and to put these before the Committee at its meeting in February.

Dr. HAMILTON said that the main purpose of the report was to suggest lines on which experimentation might follow. Dr. C. D. NEEDHAM did not agree that the tentative nature of the suggestions of the report, if they were there, could be gleaned from reading it.

Joint Consultants Committee

Dr. A. ALLISON spoke of the work of the Joint Consultants Committee (Scotland) since the last meeting. Much of the business was still under discussion with the Scottish Home and Health Department, and reports and papers on various points were awaited. The Committee was still considering its constitution and terms of reference, including the problem of representation of hospital junior staffs on the committee.

Dr. Allison reported that, owing to other commitments, Dr. C. W. Clayson had found it necessary to resign from the Advisory Committee on Consultant Establishments. The Joint Committee's nomination of Mr. J. R. Cameron, P.R.C.S.E., to replace Dr. Clayson had been accepted by the Scottish Home and Health Department.

Dr. Allison informed the committee that Dr. J. G. M. Hamilton had attended, on behalf of the Joint Consultants Committee (Scotland), a conference to consider certain aspects of the Report of the Committee on Senior Nursing Staff Structure (Salmon Committee). Dr. HAMILTON said he would be submitting a report on the conference to the Joint Consultants Committee (Scotland).

Referring to the circular on professional and study leave (S.H.M. 29/1967), Dr. C. J. MACKINLAY said that he was in no doubt that junior staff seemed happier now that something was being done for them in this matter.

The CHAIRMAN said that the Committee would like to know of instances where study leave had been held up by lack of finance. Dr. W. P. U. KENNEDY said that the South-eastern Regional Board seemed willing to pay the expenses of a doctor still in post, but this did not always apply, for example, if someone left a post to take a membership course.

Dr. GRODEN, who represented the Western Region, said that after some initial troubles all was now going well.

Health Service Inquiry

Reference was made to the statement by the Secretary of State for Scotland that he proposed to hold an inquiry into the structure of the Health Service. A paper for discussion from the Scottish Home and Health Department was still awaited.

It was reported to the Committee that the Chairman of the Association's Scottish Council had called a meeting of the chairmen of the principal committees of the Association in Scotland to discuss the method of dealing with the matter. The Chairman of the Scottish Council had said he was anxious that the profession should have an agreed attitude towards integration.

The Scottish Committee for Hospital Medical Services had not formulated a policy on integration, and the Committee agreed to await the discussion paper from the Scottish Home and Health Department before discussing the matter further.

The Committee discussed the Welsh Committee's proposals for a scheme for area health boards in Wales, and it was pointed out that it seemed that half the members of the board would be nominees of local authorities.

The Committee doubted whether this would be acceptable to hospital medical staff. It was agreed that when the document setting out the proposals was published it should be

sent to regional committees for comment, and also to hospital junior staff group committees.

Other Matters

The Committee received a report that the Scottish Home and Health Department was considering what system could be introduced to control capital expenditure by "starting dates," similar to the system which had been agreed in England and Wales. The system in Scotland might necessarily differ, but the idea behind it was to control capital building by regulating the input of new schemes into the programme rather than by requiring the expenditure to conform closely each year to an approved financial estimate.

In response to an invitation to submit views on the future development of the artificial limb services to a working party of the Scottish Home and Health Department, members of the Committee expressed satisfaction with the service provided, and the Committee as a whole thought it had no particular comment to offer. It was suggested, however, that general practitioners might have comments and suggestions to make, and the matter was referred to the G.M.S. Committee (Scotland).

It was reported to the Committee that the Western Regional Hospital Board had, on instructions from the auditors, discontinued an arrangement by which hospital doctors were paid mileage allowance by a lump sum based on an estimate of their mileage.

The Committee agreed that such a system saved both money and trouble, and that an approach should be made to the Scottish Home and Health Department with a suggestion that the system might be re-introduced.

The Committee was informed of the relevant clauses of the Health Service and Public Health Bill which affected the Scottish Hospital Service.

B.M.A. Nuffield Library

The Library service is available to all members of the Association resident in Great Britain and Northern Ireland (and by special arrangement to members of the Irish Medical Association). A copy of the library rules will be forwarded on application to the Librarian at B.M.A. House.

The following books have been added to the Library:

- Schneyer, L. H., and Schneyer, C. A. (Editors): *Secretory Mechanisms of Salivary Glands*. 1967.
 Stafford-Clark, D.: *Psychiatry for Students*, 3rd edition. 1967.
 Steptoe, P. C.: *Laparoscopy in Gynaecology*. 1967.
 Talbot, C. H.: *Medicine in Mediaeval England*. 1967.
 Taylor, R. G. W.: *Practical Cytology*. 1967.
 Watson, E. H., and Lowrey, G. H.: *Growth and Development of Children*, 5th edition. 1967.
 Wolstenholme, G., and Porter, R. (Editors): *Drug Responses in Man*. 1967.
 Wyburn, G. M., Warbrick, J. G., and Todd, M. E.: *Concise Anatomy*. 1967.
 Young, J. Z.: *The Memory System of the Brain*. 1966.

Hospitality

A German doctor living in Marl would like his 16-year-old daughter to stay with a British medical family from 28 June to 8 August as a paying guest, and would like her to attend English classes.

A South African doctor living in Johannesburg would like his 13-year-old son to stay with a British medical family during July 1968 on an exchange basis.

Would anyone who is interested please get in touch with Dr. R. A. Pallister, Medical Director, International Medical Advisory Bureau, B.M.A. House, Tavistock Square, London W.C.1.

Association Notices

Junior Members Forum

The Junior Members Forum will meet at Birmingham University on Saturday, 6 April, and Sunday, 7 April, 1968, under the Chairmanship of Dr. A. W. Macara, of Bristol. Official representatives to the Forum are drawn from junior members in the hospital service, in general practice, in public health, among university teaching staff, in the armed Forces, in industrial medicine, and in research and administration. In the case of both the hospital service and general practice Great Britain and Northern Ireland are divided into 21 electoral regions.

For the purpose of the Forum the term "junior member" is defined as "young member within 12 years of provisional registration and under the age of 40." Nominations for election of representatives are now being invited from Divisions, hospital junior staffs regional groups, and other bodies within the Association. In addition, individual junior members of the B.M.A. are invited to submit nominations for election. Such nominations should be made and seconded by junior members, with the consent of the nominee, and sent to the Secretary of the British Medical Association, Tavistock Square, London W.C.1, not later than Monday, 22 January.

D. P. STEVENSON,
Secretary.

Diary of Central Meetings

DECEMBER

- 28 Thurs. Central Ethical Committee, 10 a.m.
 28 Thurs. Executive Subcommittee (Central Committee for Hospital Medical Services), 10 a.m.
 28 Thurs. General Purposes Committee, 10.30 a.m.
 29 Fri. Chairman's Subcommittee (Full-time Medical Teachers and Research Workers Committee), 2 p.m.

JANUARY

- 3 Wed. Occupational Health Committee, 10 a.m.
 3 Wed. Private Practice Committee, 2 p.m.
 4 Thurs. Finance Committee, 2.30 p.m.
 17 Wed. Annual Meetings Committee, 10.30 a.m.
 23 Tues. Joint Consultants Committee (at Royal College of Physicians of London), 10 a.m.
 26 Fri. Venereologists Group Committee, 2 p.m.

FEBRUARY

- 6 Tues. Orthopaedic Group Committee, 2.30 p.m.

Branch and Division Meetings to be Held

HARROW AND HILLINGDON DIVISION.—At Edith Martin Memorial Hall, Roxeth Hill, Harrow, Friday, 29 December, 7.30 p.m., teens and twenties Christmas dance.

ST. MARYLEBONE DIVISION.—At 11 Chandos Street, London W., Wednesday, 27 December, 8.30 p.m., general meeting and election of representatives to Annual Representative Meeting.

Central Committee for Hospital Medical Services

The Welsh Committee's second report on area health boards did not get a ready welcome from the Central Committee for Hospital Medical Services. It recommended that the report should not be published without further amendment. Hospital junior medical staff are to have four instead of three seats on the Negotiating Subcommittee and the size of the Subcommittee is to be increased from 15 to 16 members. A memorandum from the Junior Hospital Doctors Association on the representation of junior staff was referred to the Hospital Junior Staffs Group and to the Joint Consultants Committee for comment before the Executive reported its views on it to the Committee. The Committee was dissatisfied about the Minister's action on private hospital beds, and the Joint Consultants Committee is to be asked to send a deputation to the Ministry. Lord Platt, Chairman of the Advisory Committee on Distinction Awards, addressed the Committee in private.

A meeting of the Central Committee for Hospital Medical Services (C.C.H.M.S.) was held on 14 December. Mr. H. H. LANGSTON was in the chair.

The Committee, as a constituent body, gave its formal support to some proposed changes in the composition of the Joint Consultants Committee.

Area Health Boards

The CHAIRMAN reported that the Welsh Committee had produced its second report on area health boards, which it had sought permission of the Council to publish. The Council, at its meeting on 25 October (*Supplement*, 4 November, p. 29), had deferred consideration of the report until it had obtained the comments of the Association's principal standing committees. The report had been referred by the C.C.H.M.S. to Mr. D. Lloyd Griffiths, Mr. H. A. Kidd, and Dr. G. E. Owen Williams to consider.

Mr. H. A. KIDD referred first to the constitution of an area health board, as proposed in the Welsh Committee's report, of 10 public representatives elected by county and county borough councils and 10 representatives of the professions, of whom not fewer than five would be elected by the medical advisory committee. He said there was no objection to that, provided the medical representatives were in active practice.

The second and, in Mr. Kidd's view, more worrying matter concerned private practice. It was doubtful whether there was any real provision for, and indeed little intention of provision being made for, private practice in Wales. "I see this pilot scheme as one which is intended to do away with private practice," he said.

Thirdly, Mr. Kidd thought that if the experimental scheme came into operation in Wales there should be a referendum on it at the end of five years.

Mr. D. LLOYD GRIFFITHS said that, though there was much in the report that was acceptable, it was not a good pilot experiment because it could never be undone once it was started. It would be a great pity if the success or failure of a scheme in Wales was to be a guide to the outcome of similar schemes in many parts of England where circumstances were quite different.

Dr. G. E. OWEN WILLIAMS suggested that the report seemed to have been produced by a group of enthusiasts and added to by

further enthusiasts. In his view the Committee should reserve its position on the question of hospital administration.

Dr. A. SKENE suggested that the Committee should recommend to the Council that some of the 10 public representatives on the area health board should be elected by county and county borough councils, but that there should be machinery, similar to the regional hospital board machinery, which would allow for other representatives to be elected who were not connected with local authorities. It should be recommended also, said Dr. Skene, that in the minimum of five medical members on the board there should be some direct representation of hospital medical staff.

Dr. H. GLYN JONES said it would seem from the report that general practitioners would continue to be "independent contractors." General practitioners had stated that their administrative structure should not be disturbed and that they proposed to keep it completely independent. "They are prepared to mess everybody else about, but their own administrative structure is to stay totally unchanged," he said. If there was to be one administrative structure it should be for the whole Service and no part of it should be excluded.

Mr. KIDD said that in his view it would be a mistake to allow the report to be published with the Committee's blessing. There was nothing in it to protect private practice. Dr. OWEN WILLIAMS referred to the appointment of members of area health boards by local authorities, and said it must be remembered that the proposals were not based on county authorities organized as at present but on the new regions, in each of which there would be one area health board.

The Committee decided by a large majority to recommend to the Council that the second report of the Welsh Committee on area health boards should not be published without further amendment.

Negotiating Subcommittee

The CHAIRMAN drew attention to three resolutions about the representation of hospital junior staff on the new Negotiating Subcommittee. The first was a resolution of the Annual Representative Meeting 1967:

That this Annual Representative Meeting does not approve of the action already taken by the Central Consultants and Specialists Committee

in reducing from four to three the number of junior hospital staff representatives who sit on the negotiating committee for all hospital medical staff, which has 15 seats, and asks the C.C. and S. Committee to reconsider this matter in the light of the recommendations initially made by the Joint Consultants Committee.

The second was a resolution of the Hospital Junior Staffs Group Council:

That the H.J.S. Group Council expresses dissatisfaction with the reduction from four to three of the minimum number of junior staff on the new Negotiating Subcommittee.

The third resolution was one which had been passed by the Council at its meeting on 29 November, on a motion by Dr. H. L. Leaming (*Supplement*, 9 December, p. 71):

That this Council requests that when considering the composition of the negotiating committee the Central Committee for Hospital Medical Services take note of the desirability of ensuring that it contains adequate representation not only of hospital junior staff but also of consultants working exclusively in regional board hospitals.

Dr. E. A. HARVEY-SMITH, Chairman of the Hospital Junior Staffs Group, said that his Group had always wanted a 50% representation of the Negotiating Subcommittee, but unless the total number of members on the Subcommittee was altered it was difficult to see how that could be achieved.

The CHAIRMAN said that rather than alter the total number of members on the Subcommittee it would be easier to add one more junior member at the present stage, because if the Committee considered reducing the consultant representation, which might be necessary if junior representation was to be increased, the matter would have to be referred back to the Joint Consultants Committee.

Dr. SKENE suggested that for the remainder of the session one additional member nominated by the Hospital Junior Staffs Group should be co-opted to the Negotiating Subcommittee. Mr. WALPOLE S. LEWIN thought that the time had now come for the Committee to state clearly that the hospital junior staff should have four seats on the Negotiating Subcommittee.

Mr. KIDD pointed out that of all the members of the Negotiating Subcommittee only three could really be considered to be working in regional hospitals. There were about 8,000 consultants in the country who must spend at least 20 years of their life in their work. There was also a large number of hospital junior staff, said Mr. Kidd, but most of them were not in the hospital service for more than a year. Mr. Kidd said he did not feel happy about always increasing the junior staff representation at the expense of regional consultants.

Dr. HARVEY-SMITH said that he appreciated Mr. Kidd's views, and agreed that regional consultants should be adequately represented. The bulk of the consultants in the country were working in the regions, but their representation on the Negotiating Subcommittee should not be at the expense of the hospital junior staff. Mr. KIDD observed that the hedge-sparrow was not consulted by the cuckoo when it came into its nest.

The Committee finally agreed that the number of seats for hospital junior staff on the Negotiating Subcommittee should be increased from three to four, thus raising the total number of members on the Subcommittee to 16.

Proportional Representation

Dr. H. L. LEAMING referred to the Council's resolution. He said that he thought it essential that the Central Committee for Hospital Medical Services (C.C.H.M.S.) should have the chance of considering its relationship to hospital staff in the regions and to the B.M.A. itself. The C.C.H.M.S. was serviced and financed by the B.M.A., and it was only reasonable that it should pay some attention to the Association's principles and policies. The principle of proportional representation in the Representative Body and the Council had been obtained in the new constitution, and it would mean that hospital medical staff would have more say in B.M.A. matters than ever before. Four-fifths of the consultants in the country worked exclusively in regional board hospitals, and, in Dr. Leaming's view, it was ridiculous that in a negotiating committee numbering 16 four-fifths of the consultants in the country should be represented by only three members.

Dr. OWEN WILLIAMS agreed with the need for some degree of proportional representation on a policy-making committee. The Negotiating Subcommittee had a technical job to do, and in his view a distinction should be made between a policy-making body such as the Central Committee for Hospital Medical Services, and a technical committee such as the Negotiating Subcommittee.

Distinction Awards

At this point the CHAIRMAN welcomed Lord Platt, Chairman of the Advisory Committee on Distinction Awards, who had accepted an invitation to meet the Committee, and to give his observations, *in camera*, on the results of the recent ballot on distinction awards (*Supplement*, 21 October, p. 22). LORD PLATT spoke at some length and answered many questions. At the end he was warmly thanked by the Committee.

Health Services and Public Health Bill

The CHAIRMAN informed the Committee that on the publication of the Health Services and Public Health Bill a meeting of the Medico-legal Subcommittee was convened to consider the clauses in the Bill relating to the hospital service. He invited Dr. S. Cochrane Shanks, the Subcommittee's chairman, to report on its findings.

Dr. COCHRANE SHANKS said that the most important clause in the Bill seemed to be clause 1. It did not alter the Health Minister's existing power to reduce or to increase the number of pay-beds. The Subcommittee had understood that the increased flexibility of "authorization" (as opposed to designating specific beds under the existing Acts) had been regarded by the Joint Consultants Committee as having more advantages than disadvantages, and the Medico-legal Subcommittee had seen no reason to disagree.

Dr. Cochrane Shanks said that it was not clear—and the Health Departments should be asked to clarify the point—whether a paying patient could be admitted under subsection (1) under the care of a whole-time consultant, and, if so, whether any part-time consultant

involved in the treatment of that patient would or would not be entitled to charge a fee.

Mr. ALAN SMALL reported that in the North-west Metropolitan Region pay-beds had been cut by 20% in non-teaching hospitals and by 4.1% in teaching hospitals. There was a staggering difference in the treatment of teaching hospitals and of regional hospitals. If it was impossible to effect a change in the situation he suggested that the teaching hospitals in London might make voluntary cuts so as to enable more pay-beds to remain in the regional hospitals, because there had been deliberate discrimination.

Dr. HARVEY-SMITH supported Mr. Small. It was, he said, a political manoeuvre, and the criterion adopted was based on bed occupancy, which, as everyone concerned knew, was often low because beds were used for N.H.S. patients, and once a bed was occupied by an N.H.S. patient it reduced private occupancy.

Mr. LLOYD GRIFFITHS said it was in his view a matter for regret when a member of the Committee found it necessary to emphasize the difference in treatment accorded to teaching and non-teaching hospitals. Speaking for one provincial centre, he could say that no distinction had been made whatever. The cut had been just as savage in the teaching hospital as in the non-teaching hospital. The savage reduction in private beds in his region had been made on fallacious statistics of beds that were empty because they could not be staffed by nurses.

Dr. LEAMING said that private beds were not provided in order that consultants could earn private fees. The provision of private beds was to enable patients to be treated privately if they so wished. He said that no progress would be made in arguing with the Minister unless evidence could be produced to show that patients who wanted to be treated privately had had to go into general wards.

Dr. J. F. PIGOTT drew attention to a letter from Dr. John Lister and others, which had appeared recently in *The Times*, which had referred to a reduction in the number of private beds from 5,764 to 4,379 as from 1 January 1968. It was a matter of serious concern to the Committee, said Dr. Pigott.

Mr. T. M. HENNEBRY said that the Joint Consultants Committee should continue to press the matter, although it would seem to be too late.

Dr. OWEN WILLIAMS said that he had had access to figures upon which the calculations were based in his region, and there was no gross discrepancy between the docking of beds and bed occupancy in the various categories in the different hospitals.

The Bill had nothing to do with the recent reductions in pay-beds, he said, and it concerned not only the profession and the Ministry but also the public. Dr. Owen Williams said that some thought should be given to the publicity aspect of any case put forward for private beds in hospitals in future.

The Committee agreed to request the Joint Consultants Committee to arrange for a deputation, which should include a representative of the Private Practice Committee, to go to the Ministry of Health on the matter.

Representation of Hospital Junior Staff

The Committee considered a memorandum on the representation of hospital junior staff

which had been submitted to the Council of the B.M.A. by the national executive council of the Junior Hospital Doctors Association, and referred by the Council to the Committee and to the Hospital Junior Staffs Group Council and the Organization Committee.

Dr. PIGOTT, vice-chairman of the Junior Hospital Doctors Association, presenting the memorandum, recalled that it had been prepared at the request of the B.M.A. and it outlined a new structure for the representation of junior staff. It was intended to form a basis for detailed discussions. The J.H.D.A. emphasized that its proposals outlined a democratic system but not an egalitarian one. Representation at the highest level on a basis of one doctor one vote was not asked for.

The memorandum pointed out, said Dr. Pigott, that within the B.M.A. the representation of hospital junior staff had never been satisfactory. The existing structure was paternalistic in concept and in many ways undemocratic in operation. The result was a feeling of impotence and apathy among junior staff at a time when important changes were being planned in the N.H.S.—changes which were likely to have far-reaching effects on the training and career prospects of all junior doctors. It was vital that junior doctors should play a full and equal part in the political life of the profession, and thereby have power to influence their own future.

Dr. SKENE suggested that the memorandum should be considered as a step towards the re-establishment of trust within the profession. Unless there was reasonable unity everyone was lost. Dr. Skene said he would like to think that the energetic and highly intelligent doctors running the J.H.D.A. would be able to find a way with the B.M.A. of coming together and speaking with one voice in the interest of hospital doctors.

Dr. HARVEY-SMITH, who spoke as an individual and not as chairman of the Hospital Junior Staffs Group, said that the memorandum was an honest attempt by a group of hospital doctors who thought that the existing structure was unsatisfactory to suggest improvements in junior staff representation. It was a clear, concise, and precise document which the Committee must welcome. Of course the various points set out in it had been considered in great detail before, and in many respects it sought exactly the same objectives as the Hospital Junior Staffs Group. The main difference in the proposed from the existing organization was that of keeping the junior and senior staff quite separate until their executives met in what was termed in the memorandum the "Hospital Staffs Subcommittee."

Dr. Harvey-Smith said he would not be happy about losing the Hospital Junior Staffs Group Executive's representation on the Central Committee for Hospital Medical Services, which would be the case if the proposed new structure were adopted. If an assurance could be given that the Hospital Junior Staffs Group was represented at all the discussions of the Central Committee for Hospital Medical Services he could see no difficulty in the executive of his Group and that of the J.H.D.A. meeting to form a common executive committee.

Dr. D. GUTTMANN said there were three main points which arose from the proposals set out in the memorandum. The first concerned the position of the Hospital Junior

Staffs Group Council should it become an autonomous committee; the second was the interpolation of an extra committee for the purpose of appointing the negotiating team; and the third the disappearance of the Joint Consultants Committee from the negotiating machinery.

The first two points concerned the greater representation of hospital junior staff, and the Group had been in favour of that for a long time. It was necessary to safeguard the Group's ability to achieve representation in the C.C.H.M.S. and in its various subcommittees.

Suspicion and Mistrust

In general, Dr. Guttman said, there was no doubt that the Junior Hospital Doctors Association and the Hospital Junior Staffs Group had gained support because of the suspicion and distrust between junior and senior staff. In his view that had arisen largely out of ignorance of what took place in committees—not only ignorance of what was said but of the spirit in which it was said. That ignorance had arisen in turn out of apathy. "When I see the number of junior staff in my own hospital and elsewhere who could not care less about the representation of their views or about the future of the N.H.S. and the profession, it frightens me," he continued. It was true that this was partly because 50% of hospital junior staff qualified overseas and had no intention of staying in Britain permanently. But the remaining 50% were concerned in the future of the medical services here.

Dr. Guttman said he was appalled at the difficulty encountered in getting those doctors interested in meetings at central or regional level. It was chiefly a matter of communication, he said, and he did not believe that "B.M.A. News" was enough in that respect. All members of the Central Committee for Hospital Medical Services should make it their job to arouse the interest of junior staff in committee work. "I do not think we can afford to turn a cold shoulder to any person or any body which is prepared to join us, to work with us, and to take an active interest in medico-political matters," concluded Dr. Guttman.

Dr. S. WAND drew attention to a paragraph in the memorandum which read: "It is essential that the H.J.S.G.C. have adequate funds to appoint and maintain a secretariat, to maintain communications, and to reimburse the expenses incurred by thus appointed representatives. Regional organizations must also have access to funds." As Treasurer of the Association, Dr. Wand pointed out that the additional cost of the proposals would be approximately £10,000 a year.

The CHAIRMAN assured the Junior Hospital Doctors Association that the Committee realized that there had been much discontent and distrust among junior staff which it had been slow to recognize. That was a measure of the failure in communications. The memorandum would have to be studied carefully, continued the Chairman, and he suggested it would be discourteous if it was not sent to the Joint Consultants Committee for information. It was also necessary to await the Hospital Junior Staffs Group's comments. When these had been received the

Executive Subcommittee would study the document and provide some comments on it for the consideration of the Central Committee for Hospital Medical Services.

The Chairman thought that the main weakness of the proposals in the memorandum was that junior and senior staff discussions were kept separate until they had gone far up the respective channels. It was essential that the body that ultimately met the Government should be the most powerful, well informed, and authoritative possible, and in designing any new structure that aspect must be carefully considered.

The Committee agreed that the memorandum should be sent to the Joint Consultants Committee and that the Hospital Junior Staffs Group should be asked for its views. After that the Executive Subcommittee would consider all the comments and report to the C.C.H.M.S.

Helicopter Ambulance Service

The Committee gave its full support to a proposal by the Outer Isles Division that the B.M.A. should press for the establishment of a helicopter ambulance service.

Increases in Prescriptions

The Ministry of Health reports an increase in both the number and the cost of prescriptions dispensed by chemists in England and Wales in the second and third quarters 1967 compared with the figures for corresponding periods in the previous year. The number of claims for sickness benefit was substantially higher in both quarters in 1966, and this, the Ministry states, will have affected the prescribing figures.

The number of prescriptions issued during the period April to June 1966 was 61.2 million at a cost of £33.088m.; and during the same period in 1967 67.214 million prescriptions were issued at a cost of £36.7m. In the period July to September 1966 59.1 million prescriptions were issued at a cost of £32.251m., and in the same period in 1967 62.816 million prescriptions were issued at a total cost of £34.473m.

Services for Epilepsy

The B.M.A. has appointed a working party to prepare evidence for submission to the joint subcommittee set up by the Ministry of Health's Standing Committee on Health and its Advisory Committee on Health and Welfare of the Department of Health to review the health and services for epileptics.

The members of the Advisory Committee on Health and its Working Party are Drs. Joan R. E. W. Fisher (London), R. E. W. Fisher (London), W. Lumsden (Colchester), and J. N. Walton (Newbury).

Committee on Medical Science, Education, and Research

The Council is to be urged to set up a board of science and medical education as soon as possible, on the lines proposed in a memorandum by Dr. Ronald Gibson, Chairman of Council, discussed by the Committee. The board would control the medico-scientific and medico-sociological work of the Association, excepting its publications, and would execute its functions through working groups or panels. It would also sponsor inquiries on current scientific and social problems. The board would have its own team of permanent officials.

A meeting of the Association's Committee on Medical Science, Education, and Research was held on 12 December. Mr. A. LAWRENCE ABEL was in the chair.

Labelling of Containers

Dr. N. A. Wynne, director of the poisons information centre at the Royal Victoria Infirmary, Newcastle upon Tyne, attended by invitation to speak to a resolution of the Annual Representative Meeting 1967 which had been moved by the Newcastle upon Tyne Division. The resolution, which had been referred to the Committee by the Council, stated that all commercial preparations available to the public which were poisonous if ingested or inhaled or harmful if applied to the surface of the body should have these facts stated on the label of the container, together with the name or formula of the particular substances concerned.

Dr. WYNNE explained some of the present difficulties. People had been urged to lock away all poisons, but they did not know what substances were poisonous, because it was not stated on the container. To have the manufacturer's name on the label assisted in finding out the contents of the container in cases of poisoning with an unknown substance. Better still to have the formula of the substance named on the label. Sweden had already passed legislation on those lines.

Dr. ARNOLD BROWN thought that the action was too sweeping: much more thought could be given to it.

The Committee was doubtful whether the "commercial preparations" was precise enough—it was intended to relate to anything that could be sold over the counter. Subject to a satisfactory term being decided, the Committee agreed to recommend the Council that the resolution should be the B.M.A. policy.

Science and the B.M.A.

RONALD GIBSON, Chairman of

all spoke to a memorandum setting out proposals for the establishment of a board of education and science of the British Association. He said that the image of the Association seemed to many to fall short of its founders' object of promoting the advancement of science and of maintaining the interests of the medical profession. Its activities, particularly in the last few years, had seemed to be concentrated more on the interests of the profession. Such an imbalance, he said, was not, however, a true reflection of the annual Secretary's report on the Association's medico-sociological activities. In addition, the Association's expenditure on medical research was not commensurate with its activities.

There was room, said Dr. Gibson, for expansion and rationalization of the Association's medico-scientific work. Its Planning Unit had been in operation for a relatively short time, but already it was apparent that doctors whose primary interests were clinical or academic had been impressed by the Association's new initiative. There had been a similar reaction to recent new activities undertaken by the Science Committee. Dr. Gibson believed that if the Association was to expand and redeploy its scientific activities it might attract more members, and, more important, stimulate interest in its existing members. The Association was unique in that its membership included all types of doctors in all types of practice. With this wide range of expertise to draw on the B.M.A. should be able to contribute to the medico-scientific and medico-sociological fields in a way no other medical organization could.

Dr. Gibson's memorandum proposed, as a first step, that all the routine activities already undertaken by the Committee on Medical Science, Education, and Research, together with all the other medico-scientific and medico-sociological work undertaken by the Association, including the commissioning of all investigations and reports, should be reorganized in one department of the Association. The department should be under the control of a small, carefully selected board of eminent men, who would execute its various functions through a more flexible system of working groups or panels. Such a department could sponsor inquiries not only of a medico-scientific but also of a medico-sociological nature—for example, into the social problems of "hard" and "soft" drugs, nutrition, the population explosion, stress diseases, and so on.

The expansion of its Department of Audio-visual Communication would enable the Association to disseminate information on new methods of teaching and of learning by, for instance, television and video tape, programmed learning, and computer-assisted instruction.

Board of Medical Science

The proposal was to concentrate the scientific activities of the Association under the overall direction of a board of medical science and education. The chairman should be a respected member of the profession who was a national figure in medicine. The appointment should be of a limited duration, probably five years. The board should have a membership of probably not more than ten. It would operate through the medium of specially appointed panels. A standing panel would, for example, administer the Nuffield Library and another research awards. Ad hoc panels would be appointed to perform specific tasks. Each panel would be responsible

directly to the board, and normally the board would select the chairman for each panel, would seek representation from the Council or standing committees of the Association (or from other bodies), would invite experts to serve on the panel where applicable, and would nominate one of its own number to serve on a panel when appropriate. The board would have its own team of permanent officials. It was too early at this stage, said Dr. Gibson, to say what relationship the B.M.A.'s Planning Unit should have to the board, but in due course a close liaison must evolve between them.

The initial cost of these proposals ought not to exceed the Association's existing overall scientific budget, since the "exercise" was largely a reorganization of the present activities.

Constitutional Position

The memorandum concluded by explaining the relation of the board to the Council and to the Representative Body. It would be necessary under the B.M.A.'s constitution to ensure that the Council and the Representative Body had a say in the activities of the board, but there would be a need to ensure the independence of the board and of the panels within an overall remit. It would probably emerge that the Representative Body and the Council would have an overall say in the routine administration of the board, but its expert inquiries could either be presented for specific approval or published in a new series of books or pamphlets intended to encourage discussion.

Dr. Gibson explained that this was not a new concept. The Organization Committee had suggested it some years ago as part of a general reorganization of the machinery of the Association. The Organization Committee was concerned with the membership of the Association, and the membership depended on the Association being seen to be of service to doctors in their various disciplines. Nowadays doctors needed continual support, and this the Association would continue to supply through its medico-political activities. Over the years medico-politics had come into the limelight so much that some doctors thought the Association was no longer interested in the promotion of the medical and allied sciences.

The objective of the board would be to ensure that the Association was fulfilling its responsibilities in the medical and allied sciences. There was no question of building a new department at much cost to the Association but of consolidating the existing state of affairs. By creating a board of medical science and education Dr. Gibson hoped that the B.M.A. would both enlarge its membership and prove its right to be considered a forceful entity in the field of medical science.

Discussion on Memorandum

Dr. J. WEDGWOOD said it was time that the Association gave a lead in teaching and research. It had a long way to catch up with other organizations that were doing this work. He hoped the policy would be followed with "great vigour." The facilities of the B.M.A. for research were necessarily limited, and he had thought that the Association tended to dissipate its energies over too wide a field of activity, instead of concentrating on a few. That was a virtue, but it was impractical.

Sir AUBREY LEWIS congratulated the Chairman of Council on producing such a fine statement of the position, and he hoped that the Committee would support the memorandum.

Mr. DAVID BROWN said that he had on a previous occasion asked that the Association should consider co-ordinating its work in undergraduate and postgraduate education, but his proposals had been rejected because of the shortage of money. The board suggested in the memorandum was the answer to what he had in mind, provided the emphasis was on education—particularly with a scientific background. Though the Association could not afford the money for all it might hope to do, such a new project might attract money from other sources. If it had to work on a tiny budget he could not see it developing.

Dr. B. LIVESLEY, speaking as a hospital junior doctor, said that one of the things which had driven young men from the B.M.A. was its engrossment in medico-politics. He hoped that training for specialist and general practice would come within the compass of the new department.

Dr. L. P. GRIME said that the proposed board could co-ordinate the scientific and educational activities of the B.M.A., and Dr. M. M. BULL, in hoping the project would be pursued with enthusiasm, said there should be active liaison with other interested bodies. He asked that preclinical teaching should not be forgotten. The new science of medical sociology was being given greater attention in the universities, and he was pleased to see it included in the outline of the activities of the proposed department.

Professor F. E. STOCK was concerned that the board of education and science should not become in any way separated from the rest of the B.M.A., so that there was one part which seemed to be doing only medico-political work and another the scientific work. The work of the two should be integrated. Professor D. E. C. MEKIE said that thought would have to be given to how the new body should be related to the Association. The danger that the board might be too high-powered should be avoided. It should not consist of specialists in an ivory tower. The board should cater for all types of doctors.

Dr. W. W. FULTON, speaking as a family doctor, said that the B.M.A. should guard against the idea of "them" and "us." The ordinary members should be encouraged not only to take an interest in the work of the board but also to take part in it. Dr. ARNOLD BROWN hoped that the board would be a high-powered body. It should consist of people who were respected and known for their scientific activities. That would cost money, but it would be well spent. The work of the board would, he hoped, result in an increase in B.M.A. membership, and contri-

butions from some of the voluntary societies. There should be one person on the board acquainted with the needs of the public. The board should be independent and it should answer to the Representative Body.

Dr. F. J. C. HERRALD said that the board should seriously consider what it could do best. There were some things it could do better than others, and it would be a mistake to duplicate what another body was doing.

Film Committee

The Committee discussed the position of the Film Committee in relation to the proposed board of education and science.

Sir RONALD TUNBRIDGE said that the Film Committee should not be separate, otherwise it was defeating the object of the board.

In reply to a question by Mr. R. MYLES GIBSON on what the functions of the panels would be, Dr. D. P. STEVENSON, Secretary, said that the board would choose subjects for the panels to consider. For example, the B.M.A. ought to be leading the way with opinions on contentious matters such as whether there ought to be a register of specialists and consultants. There was a new role for the Association in postgraduate centres. There was no end to its activities in medical education. The scheme was also coupled with the plan to regionalize all the activities of the Association.

Members of the Film Committee then joined the meeting. Its chairman, Dr. T. A. QUILLIAM, said that his committee was in sympathy with the new concept of integrating the scientific medical education activities of the B.M.A. The Department of Audio-visual Communications was concerned primarily with doctors, but many of its activities were financed in part by the British Life Offices Association and were directed towards the health education of the general public. He believed that in many ways the functions of the department could best be performed as an independent body.

Dr. VALERIE GRAVES said that, as a producer of educational material, she was always becoming entangled with committees who admired the technology without understanding its limitations. Producers were tired of trying to do things for people who did not know what they could do, and as a result they were suspicious of one more board. The Film Committee was worried about losing the support of the Life Offices Association, who would like to think that the Committee was committed to a definite programme. The Life Offices Association would not like to feel that the Committee's activities were to be merged with another group's activities which were not directly under the control of those to whom the money was originally given.

Fashioned to Fit

Mr. C. ENGEL, director of the Department of Audio-visual Communications, said he saw the role of his department as being to help in the implementation of education at all levels from the undergraduate up to continuing education, including health education, both in teaching and in learning. This meant that the tools had to be fashioned to fit the

end. The organization of the department must have two quite separate bases. One was on activities which were not based on any specific project but were on a continuing basis. The other was the specific projects that could be laid down from above.

After the Film Committee had had a separate discussion it returned. Dr. QUILLIAM said that it was pleased that there should be a board. However, the Film Committee had come to the conclusion that the Department of Audio-visual Communication, advised by the Film Committee as a panel, should be an autonomous organization in that it should have direct access to the board. He appreciated that there should be cross-representation with the panel on education.

Mr. MYLES GIBSON said that he was "disappointed" at the suggestion that audio-visual communication should be separated from medical education. Looking ahead, in the context of continuing medical education, the two could not reasonably be dissociated. He could not see the logic of divorcing them.

Dr. QUILLIAM wondered why the proposed board would be anxious to incorporate the Department of Audio-visual Communication in its activities. The department was an extremely important one, and he would be sorry to see its activities diluted.

The Science Committee adopted the following motions proposed by Professor MEKIE:

- (1) That the recommendations in the memorandum should be approved in principle.
- (2) That the Council should be urged to set up a board of science and medical education as soon as possible.
- (3) That details of the organization of special panels under the general direction of the board should be studied further after the formation of the board.

Postgraduate Medical Centres

The Committee agreed to recommend to the Council that the following recommendations of the Committee's working party on postgraduate medical centres should be adopted.

(1) The scientific and educational aspects of the Association's activities should be fostered by all the means at its disposal.

(2) If the report of the Royal Commission on Medical Education recommended official recognition of the educational functions of postgraduate medical centres it was probable that the centres would be linked with the local university and a local director appointed. Where such arrangements are or are coming into existence, the local B.M.A. honorary or science secretary should be consulted. He should be kept informed of all possible help which could be channelled through him to enable him to work together with the local organizer, dean, or director.

(3) In the working party's view the Association would exercise the greatest influence in centres in those areas where the Association was the only outside body helping in the arrangement of the programme. It is suggested that in these centres the Association should expand its present activities, such as the development of library facilities and audio-visual aids, and play a prominent part in cultural and social activities.

(4) The annual B.M.A. lecture for Divisions should continue to be made available, but an

attempt should be made to integrate the lecture into the programme of postgraduate medical centres.

(5) An attempt might also be made to replace or supplement the lecture by something a little more elaborate, perhaps by inviting the lecturer to take part in a panel discussion or clinicopathological conference.

(6) The Medical Science Committee might recommend to Divisions and Branches speakers or subjects which at the time were showing themselves to be extremely popular and attracting large audiences in other areas.

(7) An experiment might be undertaken into the possibility of arranging weekend meetings locally with one or two speakers from a distance taking part. It is appreciated that this would probably involve the Associa-

tion in greater expense than the cost of a B.M.A. lecture to a Division, but it is suggested that some of the money allocated for B.M.A. lectures might be used for experiment on such weekend meetings in some areas.

H.M. Forces

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Majors G. S. Midgley, M. Macintyre T.D., B. K. Madden, C. D. MacCarthy, J. H. Stranger, L. H. Allan, and W. I. N. Kessel have resigned their commissions, retaining the rank of Major.

Majors G. L. Herbert and G. F. A. Howie have resigned their commissions.
Captains (Honorary Majors) H. R. W. Lunt, T.D. R. B. Martin, C. W. J. Hunt, and J. A. R. Johnson, T.D., have resigned their commissions, retaining the honorary rank of Major.

Public Health Medical Officers' Salary Claim

Agreement on revised salary scales for public health medical officers was reached at a meeting of Whitley Committee C on 20 December. Under the early warning machinery of the Government's prices and incomes legislation the operative date of the award will be 1 July 1967, but both sides of Committee C are to approach the appropriate Ministry to ask for an earlier date. It is hoped that the secretary of the Management Side of Committee C will be able to notify local authorities of the new salary scales early in January, and an M.D.C. circular is being drafted.

Association Notices

Fellowship and Awards for Medical Research

The Council of the British Medical Association invites applications from members for the following fellowship and research awards.

Fellowship

A new whole-time research fellowship to the value of £1,500 is offered to assist research into any subject relating to the causation, prevention, or treatment of disease. It will be tenable for one year, and normally renewable for a second year subject to a satisfactory progress report.

Research Awards

The Council will also consider applications for the Ernest Hart and Walter Dixon Research Awards, each up to the value of £300, and other research awards. The awards are granted to assist specific research work in any subject relating to the causation, prevention, or treatment of disease.

Applications for the fellowship or research awards should be submitted not later than 27 January 1968. The appropriate form and information on the conditions of the awards are obtainable from the Secretary, British Medical Association, Tavistock Square, London W.C.1.

DEREK STEVENSON, *Secretary*.

Diary of Central Meetings

JANUARY

- | | | |
|----|--------|---|
| 3 | Wed. | Occupational Health Committee, 10 a.m. |
| 3 | Wed. | Private Practice Committee, 2 p.m. |
| 4 | Thurs. | Finance Committee, 2.30 p.m. |
| 5 | Fri. | Executive Subcommittee (Public Health Committee), 10 a.m. |
| 9 | Tues. | Constitution Subcommittee (G.M.S. Committee), 2.30 p.m. |
| 10 | Wed. | Joint Formulary Committee 10.30 a.m. |
| 12 | Fri. | H.J.S. Group Executive Committee, 2.30 p.m. |
| 15 | Mon. | Planning Unit-Primary Medical Care, 6 p.m. |
| 16 | Tues. | Working Party on Health and Welfare of Epileptics, 10.30 a.m. |
| 17 | Wed. | Annual Meetings Committee, 10.30 a.m. |
| 19 | Fri. | Committee on Overseas Affairs, 1.30 p.m. |
| 23 | Tues. | Joint Consultants Committee (at Royal College of Physicians of London), 10 a.m. |
| 23 | Tues. | General Medical Services Committee (Scotland), (at 7 Drumsheugh Gardens, Edinburgh), 10.30 a.m. |
| 26 | Fri. | Venereologists Group Committee, 2 p.m. |

| 14 | Wed. | Joint Formulary Committee, 10.30 a.m. |
| 19 | Mon. | Scottish Committee for Hospital Medical Services (at 7 Drumsheugh Gardens, Edinburgh), 11.15 a.m. |

Branch and Division Meetings to be Held

Members proposing to attend meetings marked ● are asked to notify in advance the honorary secretary concerned.

DUMFRIES AND GALLOWAY DIVISION.—Sunday, 7 January, Dr. W. M. Court Brown: "Some Recent Advances in Human Cytogenetics."

HAVERING DIVISION.—At Academic Unit, Oldchurch Hospital, Friday, 5 January, talk by Miss Kathleen M. Frith: "Contraception." Ladies are invited.

LEWISHAM DIVISION.—At Medical Centre, Lewisham Hospital, Friday, 5 January, 8.30 p.m., consultants' wine and cheese party and Division's social evening.

NORTH DEVON DIVISION.—Thursday, 4 January, Mr. G. Blackburn: "Thyroid Surgery."

Branch and Division Officers Elected

BARNESLEY DIVISION.—Chairman, Dr. C. G. Oddy. Honorary Secretary, Dr. D. W. Mayman.

BRIGHTON AND MID-SUSSEX DIVISION.—Chairman, Dr. N. W. A. Harvey. Chairman-elect, Mr. P. V. Wadsworth. Vice-chairman, Mr. S. H. C. Clarke. Honorary Secretary, Dr. F. E. de W. Cayley. Honorary Treasurer, Dr. J. L. Digby Roberts.

CITY OF DUNDEE DIVISION.—Chairman, Dr. J. M. Langlands. Vice-chairman, Dr. D. Green. Honorary Secretary, Dr. W. Yeaman. Honorary Treasurer, Dr. J. Scott Innes.

CONGO BORDER DIVISION.—Chairman, Dr. M. Lowenthal. Honorary Secretary and Treasurer, Dr. C. J. Goosen.

CUMBERLAND DIVISION.—Chairman, Dr. T. Mooney. Vice-chairman, Dr. A. Stevenson. Honorary Secretary and Treasurer, Dr. G. P. Raitt.

DERBYSHIRE BRANCH.—President, Dr. A. P. Tait. President-elect, Dr. E. H. B. Grey. Honorary Secretary, Dr. I. R. D. Proctor. Honorary Treasurer, Dr. R. A. A. R. Lawrence.

FOLKESTONE AND DOVER DIVISION.—Chairman, Mr. D. V. Evans. Vice-chairman, Dr. L. P. Ribet. Honorary Secretary, Dr. I. Foster.

HONG KONG BRANCH.—President, Colonel I. Walsh. Vice-President, Dr. R. G. M. Wedderburn. Honorary Secretary, Dr. Otto Y. T. Au. Honorary Treasurer, Dr. E. Y. C. Lee.

MERSEYSIDE BRANCH.—President, Dr. J. Sugden. Vice-presidents, Dr. H. C. W. Baker, Mr. J. G. Gow. Honorary Secretary and Treasurer, Dr. H. C. W. Baker.

METROPOLITAN COUNTIES BRANCH.—President, Dr. G. M. J. Slot. President-elect, Dr. E. Colin-Russ. Vice-presidents, Dr. O. S. Kohnstamm, Dr. G. Little, Dr. W. B. Pemberton, Dr. J. Wigg. Joint Honorary Secretaries, Dr. A. M. Angel, Dr. E. M. Rosser.

MID-GLAMORGAN DIVISION.—Dr. D. B. Price has been appointed Assistant Honorary Secretary of the Division.

NORTHERN IRELAND BRANCH.—President, Lieutenant-Colonel D. G. C. Whyte. President-elect, Dr. J. S. McKelvey. Vice-president, Dr. M. M. Vida Lemon. Honorary Secretary, Mr. J. W. Wilson. Assistant Honorary Secretary, Dr. J. McA. Taggart.

NORTH-WEST WALES DIVISION.—Chairman, Dr. R. Rees Prytherch. Chairman-elect, Dr. J. B. T. Griffiths. Honorary Secretary and Treasurer, Dr. W. J. Hughes.

ST. HELENS DIVISION.—Chairman, Dr. D. C. Lawton. Honorary Secretary and Treasurer, Dr. J. Sugden. Assistant Honorary Secretary, Dr. E. Wyn Jones.

WEST BROMWICH AND SMETHWICK DIVISION.—Chairman, Dr. B. Conochie. Chairman-elect, Dr. E. M. Allen. Honorary Secretary and Treasurer, Dr. J. E. Evans. Assistant Honorary Secretary, Dr. M. Ramsden.
